# Large near-surface anomalies, seismic reflection data, and simulated annealing

*Daniel H. Rothman, Ph.D.  
Stanford University, 1985*

## ABSTRACT

Where the near-surface of the Earth is irregular, seismic signals reflected from the underlying subsurface are degraded. The most important effects of near-surface anomalies are often traveltime delays called statics. Large near-surface anomalies can cause large statics that grossly distort the apparent structure of the Earth in reflection seismic sections.

To estimate (and then remove) statics, traveltime delays are measured by crosscorrelating seismograms. When statics are large, however, the lag that yields the maximum value of a crosscorrelation function may be an unreliable indicator of the true time delay. Gross errors are common.

Statics estimation is usually posed as a linear inverse problem. However, because statics estimation is actually a *nonlinear* inverse problem, linear approaches to statics estimation rely implicitly on an initial guess. I present a method for the estimation of statics that is independent of an initial guess. Statics estimation is formulated as a nonlinear inverse problem in which the estimation of the optimal statics corrections requires locating the global minimum of a multidimensional objective function.

Global optimization must avoid entrapment in suboptimal local minima. To achieve this goal, I adapt the method of simulated annealing, a Monte Carlo method that mimics the physical process by which a crystal is grown from a melt. Geophysical parameters are treated as if they were the microscopic components of a physical system. The method randomly generates new values for these parameters in a way that simulates thermal equilibrium; a control parameter analogous to absolute temperature determines the freedom with which the parameters' values are changed. A non-zero temperature allows perturbations that can either decrease or increase the objective function.

The most efficient form of the new statics estimation algorithm also uses crosscorrelation functions. Instead of picking the peaks of crosscorrelation functions to estimate time delays, the new method transforms the crosscorrelation functions to probability distributions. Estimates of time delays are then randomly drawn from these probability distributions. This procedure is repeated iteratively until a stable solution is reached.

Results are demonstrated on synthetic data and field data from the Wyoming Overthrust belt. Further applications of the method are proposed.

## Acknowledgments

This thesis has been made possible by the frequent assistance, advice, criticism, and support I have received from the students and staff of the Stanford Exploration Project (SEP), the research group of which I have been a member. Those to whom I feel especially indebted include Paul Fowler, Stew Levin, Peter Mora, Francis Muir, Rick Ottolini, Fabio Rocca, Shuki Ronen, Chuck Sword, and John Toldi. Their help has been invaluable.

Financial support for this work was provided by the Amoco Foundation and the industrial sponsors of the SEP. Among the sponsors, I am most grateful to Jim Johnson of Conoco for providing the field data used in this thesis. I would also like to thank Ken Larner and Ron Chambers of Western Geophysical for the interest they have shown in this work.

Aside from the members and sponsors of the SEP, I benefited from many discussions with Rob Haar, Dale Morgan, Mike Schlax, and Norm Sleep.

I thank those among the aforementioned who critically read early drafts of this thesis. I am also grateful to Fannie Toldi for her work as an editor.

Finally, I thank my advisor, Jon Claerbout, not only for his advice, encouragement, and interest, but also for his insistence that this thesis emphasize concrete facts over speculations.

# Table of Contents

Abstract .....	iii
Acknowledgments .....	v
List of figures .....	ix
<b>Chapter 1 Introduction</b> .....	1
1.1 Overview .....	1
1.2 Structure .....	3
<b>Chapter 2 Large near-surface anomalies</b> .....	5
2.1 Statics observed: field profile .....	6
2.2 Statics observed: common midpoint gathers and stacks .....	8
2.3 Surface-consistency .....	11
2.4 Cycle-skips and the estimation of time delays .....	11
2.5 A probabilistic perspective .....	16
<b>Chapter 3 Residual statics estimation by simulated annealing: theory</b> .....	19
3.1 A model for surface-consistent statics .....	20
3.2 Statics estimation and computational intractability .....	22
3.3 Simulated annealing .....	25
3.4 General issues of practical importance .....	33
3.5 The algorithm as a Markov chain .....	35
<b>Chapter 4 Residual statics estimation by simulated annealing: results</b> .....	39
4.1 Synthetic data example .....	40
4.2 Field data example .....	48
4.3 Discussion .....	67
<b>Chapter 5 General theory and further applications</b> .....	69
5.1 Nonlinear inversion and optimization .....	69
5.2 Gibbs-Markov models .....	72
5.3 Bayesian formulation .....	75
5.4 Residual statics estimation: a new perspective .....	76
5.5 Future applications .....	79
5.6 Two useful concepts from statistical mechanics .....	81
<b>Chapter 6 Conclusions</b> .....	83

<b>Appendix The Markov chain and its steady state</b> .....	87
A.1 Preliminaries .....	87
A.2 The transition-probability matrix .....	88
A.3 Irreducibility .....	89
A.4 Aperiodicity .....	90
A.5 The steady state .....	91
References .....	93

## List of Figures

2.1	A reflection seismic experiment .....	6
2.2	Field profile .....	7
2.3	Common midpoint (CMP) gather .....	8
2.4	CMP gathers and stack before statics corrections .....	10
2.5	CMP gathers and stack after statics corrections .....	10
2.6	Two seismograms from CMP gather 118 .....	13
2.7	Crosscorrelation of the two seismograms in Figure 2.6 .....	13
2.8	Two seismograms from CMP gather 34 .....	14
2.9	Crosscorrelation of the two seismograms in Figure 2.8 .....	14
2.10	CMP gathers and stack after inaccurate statics corrections .....	15
2.11	A probability distribution obtained from a crosscorrelation function .....	16
3.1	The objective function $E(\mathbf{x})$ .....	23
3.2a	A normalized crosscorrelation function .....	31
3.2b	A probability distribution obtained from Figure 3.2a, with $T = .044$ .....	32
3.2c	A probability distribution obtained from Figure 3.2a, with $T = .013$ .....	32
4.1a	Four synthetic CMP gathers .....	41
4.1b	The desired stack .....	41
4.2	Random shot and receiver statics .....	42
4.3a	CMP gathers after application of random statics .....	42
4.3b	Input stack .....	43
4.4a	Stack after 2410 iterations .....	43
4.4b	Stack after 3080 iterations .....	44
4.4c	Stack after 4540 iterations .....	44
4.4d	CMP gathers after application of statics solution .....	45
4.4e	Stack power versus iteration number .....	45
4.5	Difference between estimated statics and model statics .....	46
4.6	Stack, iterative improvement .....	46
4.7a	Input stack (field data) .....	52
4.7b	CMP gathers 34 and 64, before statics corrections .....	53
4.8a	Stack after 5 iterations .....	54
4.8b	Stack after 1000 iterations .....	55
4.8c	Stack after 1125 iterations .....	56
4.8d	Stack after 1250 iterations .....	57
4.8e	Stack after 1835 iterations .....	58
4.9	Stack power versus iteration number .....	59
4.10	CMP gathers 34 and 64, after statics corrections .....	60
4.11	Shot and receiver statics output by iteration 1835 .....	61

4.12	Stack, shift limit increased .....	62
4.13	Shot and receiver statics after shift limit was increased .....	63
4.14	Stack, linear trend removed .....	64
4.15	Shot and receiver statics after linear trend was removed .....	65
4.16	Stack, iterative improvement .....	66
5.1	A two-dimensional Markov random field .....	73
5.2	Spatial organization of residual statics estimation .....	78
