4.1 Extrapolation of Magnetotelluric Wave Fields

by Robert H. Brune & Jon F. Claerbout

4.1.I. Electromagnetic Waves: Frequency Domain Finite Difference Techniques

We will first consider transverse electric waves, then the transverse magnetic case. Maxwell's equations are (in MKS):

$$\nabla \times E = -\dot{B} \tag{1}$$

$$\nabla \times H = J + \dot{D} \tag{2}$$

We assume $\dot{D} \approx 0$ in equation (2) and remember Ohm's law, $J = \sigma E$, and that $B = \mu H$. Equation (2) by components is (using superscripts for components):

$$\partial_y (B^z/\mu) = 0 \tag{3a}$$

$$-\partial_y (B^x/\mu) = 0 \tag{3b}$$

$$-\partial_x (B^z/\mu) + \partial_z (B^x/\mu) = \sigma E^y \tag{3c}$$

Take B to have time dependence $B_o e^{-i\omega t}$; eq. (1) by components is then:

$$-\partial_z E^y = i\omega B^x \tag{4a}$$

$$\partial_x E^y = i\omega B^z \tag{4b}$$

Substitute equations (4) into (3c):

$$-\partial_x [(1/\mu) \partial_x (E^y/i\omega)] + \partial_z [(1/\mu) \partial_z (E^y/i\omega)] = \sigma E^y$$

For μ as a function of x only, we have (using subscripts for derivatives):

$$E^y_{xx} + E^y_{zz} - (\mu_x/\mu) E^y_x = -\ell^2 E^y \quad ; \quad \ell = (i\omega\mu\sigma)^{1/2} \tag{5}$$

Now, let's consider a perturbation technique:

$$E^y = Q(x, z)\, e^{i\ell z}$$

Then:

$$E^y_x = Q_x \, e^{i\ell z} \tag{7a}$$

$$E^y_{xx} = Q_{xx} \, e^{i\ell z} \tag{7b}$$

$$E^y_{zz} = (Q_{zz} + 2 \, i \, \ell \, Q_z - \ell^2 \, Q) \; e^{i\ell z} \tag{7c}$$

Substituting equations (7) into (5) and dropping Q_{zz} (parabolic approximation) yields:

$$Q_{xx} - (\mu_x/\mu) \, Q_x = - 2 \, i \, \ell \, Q_z \tag{8}$$

This equation can be solved by Crank Nicolson technique. A sample program to solve (8) where $\mu_x = 0$ is given in Example A.

Before going on, let's consider the parallel development for the transverse magnetic problem. Writing equation (1) by components:

$$\partial_y E^z = 0 \tag{9a}$$

$$- \partial_y E^x = 0 \tag{9b}$$

$$- \partial_x E^z + \partial_z E^x = - i \, \omega \, B^y \tag{9c}$$

where B has $e^{-i\omega t}$ time dependence. Similarly, equation (2) by components is:

$$- \partial_z (B^y/\mu) = \sigma \, E^x \tag{10a}$$

$$\partial_x (B^y/\mu) = \sigma \, E^z \tag{10b}$$

Substituting equations (10) into equation (9c) gives:

$$\partial_x [(1/\sigma) \, \partial_x (B^y/\mu)] + \partial_z [(1/\sigma) \, \partial_z (B^y/\mu)] = - i \, \omega \, B^y \tag{11}$$

Now, let's take σ , μ to be functions of x only:

$$B^y_{zz} + B^y_{xx} + B^y_x \left(- 2 (\mu_x/\mu) - (\sigma_x/\sigma) \right)$$

$$+ B \left(- (\mu_{xx}/\mu) + 2 (\mu_x/\mu)^2 + (\mu_x \sigma_x/\mu\sigma) + \ell^2\right) = 0 \qquad (12)$$

The equation can now be solved by perturbation:

$$B^y = Q (x, z) e^{i\ell z} \quad \text{with} \quad \ell = \ell(x)$$

Thus

$$B^y_x = (Q_x + i \ell_x z Q) e^{i \ell z}$$

$$B^y_{xx} = (Q_{xx} + 2 i \ell_x z Q_x - \ell_x^2 z^2 Q) e^{i \ell z}$$

$$B^y_{zz} = (Q_{zz} + 2 i \ell Q_z - \ell^2 Q) e^{i \ell z}$$

Substituting into (12), dropping Q_{zz} , and cancelling the exponential:

$$- 2 i \ell Q_z = Q_{xx} + Q_x (2 i\ell_x z + C)$$

$$+ Q (- \ell_x^2 z^2 + i\ell_x C + D) \qquad (13)$$

where

$$C = (- 2 (\mu_x/\mu) - (\sigma_x/\sigma))$$

$$D = (- C (\mu_x/\mu) - (\mu_{xx}/\mu))$$

A more practical problem is to reconsider (from equation (11)):

$$\partial_x [(1/\sigma) \partial_x B^y] + \partial_z [(1/\sigma) \partial_z B^y] = i \mu \omega B^y \qquad (14)$$

with the realistic assumptions that μ is constant and σ is a function of x and z. We then have:

$$B_{zz} + B_{xx} - (\sigma_x/\sigma)\, B_x - (\sigma_z/\sigma)\, B_z = - i\, \mu\, \sigma\, \omega\, B = -\ell^2\, B \qquad (15)$$

Now, we use a perturbation:

$$B = Q\, e^{i\phi}\ , \text{ where } \phi = \int_0^z \ell\ dz \qquad (16)$$

$$B_x = (Q_x + i\, \phi_x\, Q)\, e^{i\phi} \qquad (16a)$$

$$B_{xx} = (Q_{xx} + 2\, i\, \phi_x\, Q_x + Q\, [i\, \phi_{xx} + (i\, \phi_x)^2])\, e^{i\phi} \qquad (16b)$$

$$B_z = (Q_z + i\, \ell\, Q)\, e^{i\phi} \qquad (16c)$$

$$B_{zz} = (Q_{zz} + 2\, i\, \ell\, Q_z + Q\, [i\, \ell_z + (i\, \ell)^2])\, e^{i\phi} \qquad (16d)$$

Substituting equations (16) into equation (15) and cancelling the exponential:

$$(- 2\, i\, \ell + (\sigma_z/\sigma))\, Q_z = Q_{xx} + Q_x\, (2\, i\, \phi_x - (\sigma_x/\sigma))$$

$$+ Q\, (i\, \ell_z + i\, \phi_{xx} - (\phi_x)^2 - (\sigma_x/\sigma)\, i\, \phi_x - (\sigma_z/\sigma)\, i\, \ell) \qquad (17)$$

A program to solve this is given in Example B. The use of equation (16) in B is not the ideal; Part III deals with further frequency domain techniques which appear to work better.

4.1.II. Electromagnetic Waves: Time Domain Recursions .

First we note that all the solutions in Section I were in the frequency domain. In this section we want to consider similar problems in the time domain. Initially let's consider how to solve the one dimensional equation:

$$Q_z = (- i \omega \mu \sigma)^{1/2} \; Q \tag{1}$$

First we change notation: drop superscripts for components and subscripts for derivatives. Then let's use superscripts for z coordinate and subscripts for time, t, coordinate. Using finite differences with this notation we can write:

$$(Q^{N+1} - Q^N) = - \underbrace{\frac{\Delta z}{2} \left(\frac{\mu\sigma}{\Delta t} \right)^{1/2}}_{\text{denote as A, a constant}} \underbrace{(-i \omega \Delta t)^{1/2}}_{\text{denote as S}} (Q^{N+1} + Q^N)$$

or,

$$(1 + A S) Q^{N+1} = (1 - A S) Q^N \tag{2}$$

There are two ways to proceed from here. Both will require the development of time domain coefficients for the half order derivative operator S. Example C gives this development for both half order derivative and integral operators.

The first way to solve equation (2) is the more obvious, but is relatively expensive. Rewrite equation (2) in time domain as:

$$P_t^{N+1} + A \sum_{\tau=0}^{t} s_\tau \, P_{t-\tau}^{N+1} = P_t^N - A \sum_{\tau=0}^{t} s_\tau \, P_{t-\tau}^N$$

Rearranging we get a recurrence relation for increasing time and depth

$$[\ 1 + A\ s_0\ ]\ P_t^{N+1}$$

$$= [\ 1 - A\ s_0\ ]\ P_t^N \quad - \quad A \sum_{\tau=1}^{t} s_\tau\ [\ P_{t-\tau}^{N+1} \ + \ P_{t-\tau}^N\ ]$$

Appendix D contains a program for this equation.

However, there is an alternate way to solve equation (2). First we observe from equation (2) that to get, for example Q^1, from Q^0 we have:

$$Q^1 = \frac{1 - AS}{1 + AS}\ Q^0$$

Hence, we might then postulate Q^N to be of the form indicated for Q^1, i.e.,

$$Q^N = \frac{U^N - A\ S\ V^N}{U^N + A\ S\ V^N} \tag{3}$$

Substituting equation (3) into equation (2):

$$\frac{U^{N+1} - A\ S\ V^{N+1}}{U^{N+1} + A\ S\ V^{N+1}} = \frac{1 - A\ S}{1 + A\ S} \quad \frac{U^N - A\ S\ V^N}{U^N + A\ S\ V^N}$$

Matching even and odd powers of S in either the numerator or denominator (note: same recursion for both numerator and denominator):

$$\text{even:} \qquad U^{N+1} = U^N + (A\ S)^2\ V^N$$

$$\text{odd:} \qquad V^{N+1} = U^N + V^N$$

This recursion is still in the frequency domain, as is equation (2). We use the bilinear approximation:

$$S^2 \approx 2\ \frac{1-z}{1-z}$$

where z is the z transform variable to write:

$$U_t^{N+1} = -U_{t-1}^{N+1} + U_t^N + U_{t-1}^N + 2A^2 [\, V_t^N - V_{t-1}^N \,]$$

and (4 a,b)

$$V_t^{N+1} = U_t^N + V_t^N$$

At this point we see to solve equation (2) for any given z level, we use the recursions of equations (4 a,b) to obtain U, V at the desired level, then find Q by equation (3). Note that in equation (3) we have the half order operator S for which we obtained the time domain representation in Example C.

If we desire to solve equation (2) for all z then there is no advantage to the technique just discussed. However, to solve for a deep z level only, we have only to perform the recursions of equations (4 a,b) for intermediate z levels. A program is given in Example E.

Having outlined a one dimensional time domain solution that was based on assuming a solution of the form of equation (3), let's now consider the two dimensional problem:

$$Q_z = \frac{-1}{2(-i\omega\mu\sigma)^{1/2}} \, Q_{xx} \tag{5}$$

Examples are equation (8) or equation (11) of section I with μ, σ constant. Proceeding as in the one dimensional case:

$$Q^{N+1} - Q^N = -\underbrace{\frac{\Delta z}{4}\left(\frac{\Delta t}{\mu\sigma}\right)^{1/2}}_{\text{denote as } A_2} \underbrace{\frac{1}{(-i\omega\Delta t)^{1/2}}}_{\text{denote as } S} \underbrace{[T]}_{\substack{\text{second} \\ \text{difference} \\ \text{operator}}} (Q^N + Q^{N+1})$$

$$(I + A_2 S T) \, Q^{N+1} = (I - A_2 S T) \, Q^N \tag{6}$$

Rewriting in time domain:

$$(I + A_2 \, s_o \, T) \, Q_t^{N+1} = Q_t^N - A_2 \, T \, (\, s_o \, Q_t^N + \sum_{\tau = 0}^{t} s_\tau \, (Q_{t-\tau}^{N+1} + Q_{t-\tau}^N \,)) \qquad (7)$$

This recursion in z and t then requires a solution for the tridiagonal operator T on the left hand side. A program for this "expensive" solution is given in Example F.

The extension of the one dimensional technique to give a recursion on U and V would be desirable. However, there apparently are problems in this approach. Consider how we might want to get from Q^0 to Q^2 by equation (6):

$$Q^1 = (I + A_2 \, S \, T)^{-1} (I - A_2 \, S \, T) \, Q^0$$

then,

$$Q^2 = (I + A_2 \, S \, T)^{-1} (I - A_2 \, S \, T) (I + A_2 \, S \, T)^{-1} (I - A_2 \, S \, T) \, Q^0 \qquad (8)$$

Now, if $(I + A_2 \, S \, T)^{-1}$ and $(I - A_2 \, S \, T)$ were to commute, then we could write:

$$(I + A_2 \, S \, T)^N \, Q^N = (I - A_2 \, S \, T)^N \, Q^0$$

If this were the case, then we could develop an algorithm as for the one dimensional case: however, the two terms in question do not commute. We might be lead to try to expand $(I + A_2 \, S \, T)^{-1}$ in a power series:

$$(I + A_2 \, S \, T)^{-1} = I - (A_2 \, S \, T) + (A_2 \, S \, T)^2 - (A_2 \, S \, T)^3 + \cdots$$

Disregarding questions of convergence, etc., we see to substitute into equation (8) so that we have products like:

$$[\, I - (A_2 S \, T) + (A_2 S \, T)^2 - (A_2 S \, T)^3 + \cdots] \, [\, I - A_2 S \, T \,]$$

All the terms now commute, but we have terms like T^k with large k : there is no gain in efficiency, even if the power series is valid.

We leave economic techniques for our two dimensional problem as an open question.

4.1.III. Electromagnetic Waves: Further Frequency Domain Techniques

Equation (15) of part I is: (TM; gradient in x,z for σ ; μ constant):

$$B_{zz} + B_{xx} - \frac{\sigma_x}{\sigma} B_x - \frac{\sigma_z}{\sigma} B_z = - \ell^2 B \qquad (1)$$

$$\ell = (i \omega \mu \sigma)^{1/2}$$

let $B = Q e^{i\bar{\ell}z}$

$B_x = Q_x e^{i\bar{\ell}z}$

$B_{xx} = Q_{xx} e^{i\bar{\ell}z}$

$B_z = (Q_z + i \bar{\ell} Q) e^{i\bar{\ell}z}$

$B_{zz} = (Q_{zz} + 2 i \bar{\ell} Q_z - \bar{\ell}^2 Q) e^{i\bar{\ell}z}$

Substituting into (1):

$$(Q_{zz} + 2 i \bar{\ell} Q_z - \bar{\ell}^2 Q) + Q_{xx} - \frac{\sigma_x}{\sigma} Q_x - \frac{\sigma_z}{\sigma} (Q_z + i \bar{\ell} Q) + \ell^2 Q = 0$$

Dropping Q_{zz} and rearranging:

$$(2 i \bar{\ell} - \frac{\sigma_z}{\sigma}) Q_z + Q_{xx} - \frac{\sigma_x}{\sigma} Q_x + (\ell^2 - \bar{\ell}^2 - i \bar{\ell} \frac{\sigma_z}{\sigma}) Q = 0 \qquad (2)$$

Now $Q = B e^{-i\bar{\ell}z}$

$Q_x = B_x e^{-i\bar{\ell}z}$

$Q_{xx} = B_{xx} e^{- i\bar{\ell}z}$

$Q_z = (B_z - i \bar{\ell} B) e^{- i\bar{\ell}z}$

Substituting into equation (2):

$$(2 i\bar{\ell} - \frac{\sigma_z}{\sigma})(B_z - i\bar{\ell} B) + B_{xx} - \frac{\sigma_x}{\sigma} B_x + (\ell^2 - \bar{\ell}^2 - i\bar{\ell} \frac{\sigma_z}{\sigma})B = 0$$

Rearranging:

$$(\frac{\sigma_z}{\sigma} - 2 i\bar{\ell}) B_z = B_{xx} - \frac{\sigma_x}{\sigma} B_x + (\ell^2 + \bar{\ell}^2) B \qquad (3)$$

Finally, we take the important step of replacing $\bar{\ell}$ by ℓ. This is justified because dropping Q_{zz} was a "local" approximation, i.e. it depended on the "goodness" of $e^{i\bar{\ell}z}$ locally to make Q_{zz} small. Using ℓ instead of $\bar{\ell}$ in (3) should locally improve the approximation:

$$(\frac{\sigma_z}{\sigma} - 2 i\ell) B_z = B_{xx} - \frac{\sigma_x}{\sigma} B_x + 2 \ell^2 B \qquad (4)$$

Example G gives a program for equation (4).

By dropping Q_{zz} to get equation (2) we are limiting the validity of our calculations to propagation in directions that are close to the z-axis. To increase this range of angles we may solve (2) for Q_z, then differentiate to find an approximation to the Q_{zz} term that was dropped. For simplicity let:

$$A = \frac{\sigma_z}{\sigma} - 2 i \bar{\ell}$$

$$E = \ell^2 - \bar{\ell}^2 - i \bar{\ell} \frac{\sigma_z}{\sigma} \qquad (5)$$

$$C = \frac{\sigma\sigma_{xz} - \sigma_x\sigma_z}{\sigma^2}$$

$$D = \frac{\sigma\sigma_{zz} - \sigma_z\sigma_z}{\sigma^2}$$

Then we substitute the approximation to Q_{zz} into equation (4); using equations (5) and rearranging, we get:

$$Q_z\left(A - \frac{E}{A}\right) + Q_{xz}\left(\frac{\frac{\sigma_x}{\sigma}}{A}\right) + Q_{xxz}\left(-\frac{1}{A}\right) = Q_{xx}\left(1 - \frac{D}{A^2}\right) + Q_x\left(\frac{\sigma_x}{\sigma}\left\{\frac{D}{A^2} - 1\right\} - \frac{C}{A}\right)$$

$$+ Q\left(E + \frac{2\ell\ell_z - i\bar{\ell}D}{A} - \frac{ED}{A^2}\right) \qquad (6)$$

This equation could be solved efficiently. However, we choose to follow through with the development at the beginning of Part III in order to increase accuracy. We will go back to an equation in B and then set the $\bar{\ell}$'s to ℓ's . First we write:

$$Q = B\, e^{-i\bar{\ell}z}$$

$$Q_{xz} = \left(B_{xz} - i\bar{\ell}\, B_x\right)e^{-i\bar{\ell}z}$$

$$Q_{xxz} = \left(B_{xxz} - i\bar{\ell}\, B_{xx}\right)e^{-i\bar{\ell}z}$$

Q_x , Q_{xx} , and Q_z are as before.

Substituting into equation (6) gives:

$$\left(A - \frac{E}{A}\right)\left(B_z - i\bar{\ell}\, B\right) + \left(\frac{\frac{\sigma_x}{\sigma}}{A}\right)\left(B_{xz} - i\bar{\ell}\, B_x\right) + \left(-\frac{1}{A}\right)\left(B_{xxz} - i\bar{\ell}\, B_{xx}\right) =$$

$$\left(1 - \frac{D}{A^2}\right)\left(B_{xx}\right) + \left(\frac{\sigma_x}{\sigma}\left\{\frac{D}{A^2} - 1\right\} - \frac{C}{A}\right)\left(B_x\right) + \left(E + \frac{2\ell\ell_z - i\bar{\ell}D}{A} - \frac{ED}{A^2}\right) B$$

Rearranging and setting $\bar{\ell}$ to ℓ we get:

$$B_z\left(A - \frac{E}{A}\right) + B_{xz}\left(\frac{\frac{\sigma_x}{\sigma}}{A}\right) + B_{xxz}\left(-\frac{1}{A}\right) = B_{xx}\left(1 - \frac{D}{A^2} - \frac{i\ell}{A}\right)$$

$$+ B_x\left(\frac{\sigma_x}{\sigma}\left[\frac{D}{A^2} - 1 + \frac{i\ell}{A}\right] - \frac{C}{A}\right) + B\left(E + \frac{\ell}{A}\left[2\ell_z - iD\right] - \frac{ED}{A^2} + i\ell\left[A - \frac{E}{A}\right]\right) \quad (7)$$

Now let's consider the problem of multiply reflected waves as in a layered structure. We can first solve for downgoing propagation; then we consider:

$$B = B^+ + B^-$$

$$= Q^+ e^{i\bar{\ell}z} + Q^- e^{-i\bar{\ell}z}$$

We are writing B as the sum of its upgoing and downgoing parts, each as a perturbation about a complex exponential. Next:

$$B_z = \left(Q_z^+ + i\,\bar{\ell}\,Q^+\right)e^{i\bar{\ell}z} + \left(Q_z^- - i\bar{\ell}\,\bar{Q}\right)e^{-i\bar{\ell}z}$$

$$B_{zz} = \left(Q_{zz}^+ + 2\,i\bar{\ell}\,Q_z^+ - \bar{\ell}^2\,Q^+\right)e^{i\bar{\ell}z} + \left(Q_{zz}^- - 2i\bar{\ell}\,Q_z^- - \bar{\ell}^2\,Q^-\right)e^{-i\bar{\ell}z}$$

$$B_x = Q_x^+ e^{i\bar{\ell}z} + Q_x^- e^{-i\bar{\ell}z}$$

$$B_{xx} = Q_{xx}^+ e^{i\bar{\ell}z} + Q_{xx}^- e^{-i\bar{\ell}z}$$

Substituting into equation 15 of Part I,

$$\left[\left(Q_{zz}^+ + 2\,i\bar{\ell}\,Q_z^+ - \bar{\ell}^2\,Q^+\right)e^{i2\bar{\ell}z} + \left(Q_{zz}^- - 2\,i\,\bar{\ell}\,Q_z^- - \bar{\ell}^2\,Q^-\right)\right]$$

$$+ \left[Q_{xx}^+ e^{i2\bar{\ell}z} + Q_{xx}^-\right] - \frac{\sigma_x}{\sigma}\left[Q_x^+ e^{i2\bar{\ell}z} + Q_x^-\right]$$

$$- \frac{\sigma_z}{\sigma}\left[\left(Q_z^+ + i\bar{\ell}\,Q^+\right)e^{i2\bar{\ell}z} + \left(Q_z^- - i\bar{\ell}\,Q^-\right)\right] = -\ell^2\left[Q^+ e^{i2\bar{\ell}z} + Q^-\right]$$

Dropping Q^-_{zz} and all terms in Q^+ except Q^+_{zz} (in other words we drop those terms in Q^+ for which we have solved when finding the downgoing wave) :

$$Q^+_{zz}\, e^{i2\bar{\ell}z} + Q^-_z\left(- 2i\bar{\ell} - \frac{\sigma_z}{\sigma} \right) + Q^-_{xx} + Q^-_x \left(-\frac{\sigma_x}{\sigma} \right)$$

$$+ Q^-\left(\ell^2 - \bar{\ell}^2 + i\bar{\ell}\,\frac{\sigma_z}{\sigma} \right) = 0$$

This is then an equation for the upward propagation with a source term that involves Q^+_{zz} .

Now

$$Q^- = B^-\, e^{i\bar{\ell}z}$$

$$Q^-_z = \left(B^-_z + i\bar{\ell}\, B^- \right) e^{i\bar{\ell}z}$$

$$Q^-_{zz} = \left(B^-_{zz} + 2\, i\bar{\ell}\, B^- - \bar{\ell}^2\, B^- \right) e^{i\bar{\ell}z}$$

also $$Q^+ = B^+\, e^{-i\bar{\ell}z}$$

$$Q^+_{zz} = \left(B^+_{zz} - 2\, i\bar{\ell}\, B^+_z - \bar{\ell}^2\, B^+ \right) e^{-i\bar{\ell}z}$$

Substituting into equation (8) gives:

$$\left(2\, i\, \bar{\ell} + \frac{\sigma_z}{\sigma} \right) B^-_z = B^-_{xx} - \frac{\sigma_x}{\sigma}\, B^-_x + B^-\left(\ell^2 + \bar{\ell}^2 \right)$$

$$+ \left(B^+_{zz} - 2\, i\bar{\ell}\, B^+_z - \bar{\ell}^2\, B^+ \right) \qquad (9)$$

Finally, we again set the $\bar{\ell}$'s to ℓ . A program and some comments on the problems encountered in this approach are found in Example I.

Example A: Frequency Domain Finite Difference Technique for T.E. or T.M. with Constant μ and σ.

The program uses an implicit scheme with 2 levels in z (Crank Nicolson):

Plot real part of solution

This output is a plot of amplitudes of a transverse E or H component (in and - out of plane of paper). It represents the solution for one frequency over the x , z plane. The top row represents the boundary conditions.

Example B: Frequency Domain Finite Difference Technique for T.M. with μ constant and σ a function of x, z .

Equation (17) of section I in finite difference notation with superscripts on Q for z-coordinate and subscripts on Q for x-coordinate:

$$\underbrace{\left[-\frac{2i\ell}{\Delta z} + \frac{\partial_z \sigma}{\sigma \Delta z} \right]}_{C1} \left(Q_x^{N+1} - Q_x^N \right) = \underbrace{\left[\frac{1}{2\Delta x^2} \right]}_{C2} \left(Q_{x+1}^N - 2\, Q_x^N + Q_{x-1}^N + Q_{x+1}^{N+1} - 2\, Q_x^{N+1} + Q_{x-1}^{N+1} \right)$$

$$+ \underbrace{\left[\frac{i}{2\Delta x} \int \partial_x \ell \, dz - \frac{\partial_x \sigma}{4\sigma \Delta x} \right]}_{C3} \left(Q_{x+1}^N - Q_{x-1}^N + Q_{x+1}^{N+1} - Q_{x-1}^{N+1} \right)$$

$$+ 1/2 \underbrace{\left[i\, \partial_z \ell + i \left\{ \partial_{xx} \ell \, dz - \left\{ \left(\partial_x \ell \, dz \right)^2 - \frac{\partial_x \sigma}{\sigma} i \int \partial_x \ell \, dz - \frac{\partial_z \sigma}{\sigma} i\ell \right] \right.}_{C4} \left(Q_x^N + Q_x^{N+1} \right)$$

C1, ..., C4 are as used in the program; rearranging, we get the tridiagonal system:

$$\left[-C2 + C3 \right] Q_{x-1}^{N+1} + \left[C1 + 2 * C2 - C4 \right] Q_x^{N+1} + \left[-C2 - C3 \right] Q_{x+1}^{N+1}$$

$$= \left[C2 - C3 \right] Q_{x-1}^N + \left[C1 - 2 * C2 + C4 \right] Q_x^N + \left[C2 + C3 \right] Q_{x+1}^N$$

There is one final detail to be taken care of: we have a one way wave equation and we have "secondary sources" at the contrasts in σ . It is necessary to halve these secondary sources since we are modeling only that secondary energy propagated in one direction.

The values here are complex amplitudes over the x , z plane for two abutting quarter spaces of conductivities .01 on left and .015 on right. The contours should decrease monotonically from right to left. The excessive "droop" of the contours at, and to the left of the vertical contact appears to be due to "incorrect" propagation of energy from secondary sources along the contact. Essentially, the method in this Example doesn't work.

Example C: Time Domain Coefficients for Half Order Derivative and Integral.

The time domain representation of the half order operators is obtained by matching coefficients of various powers of the complex variable z ; e.g.:

$$\left(\frac{1}{(-i\omega\Delta t)^{1/2}} \right)^2 = \frac{1+z}{2(1-z)}$$

letting $SI(z)$ be the half order integral operator:

$$2\,(1-z)\,[(\,1 + SI_1\, z + SI_2\, z^2 + \cdots)^2\,] = 1 + z$$

or, letting $b_i = \frac{1}{\sqrt{2}}\, SI_i$,

$$(1 - z)\,[\sum_{k=0}^{\infty} z^k \left(\sum_{i=0}^{k} b_{k-i}\; b_i \right)] = 1 + z$$

Matching coefficients of z^0 and z gives $b_0 = b_1 = 1$

For z^k , $k > 1$, we have:

$$\sum_{i=0}^{k} b_{k-i}\; b_i - \sum_{i=0}^{k-1} b_{k-1-i}\; b_i = 0$$

Rearranging:

$$b_k\, b_0 + (b_k - b_{k-1})\, b_0 + \sum_{i=1}^{k-1} (b_{k-i} - b_{k-1-i})\, b_i = 0$$

With b_0 known we have:

$$b_k = \frac{1}{2}\, [\, b_{k-1} - \sum_{i=1}^{k-1} (b_{k-i} - b_{k-1-i})\, b_i \,]$$

Given the coefficients, SI_i , for the half order integral operator, we can find the half order derivative:

$$\frac{1}{(-i\omega\Delta t)^{1/2}} \; (- i\, \omega\, \Delta\, t) = (i\, \omega\, \Delta\, t)^{1/2}$$

or, in terms of z transforms:

$$(SI_0 + SI_1\, z + SI_2\, z^2 + \cdots)\; 2\; \frac{1-z}{1+z} = (SD_0 + SD_1\, z + SD_2\, z^2 + \cdots)$$

Matching coefficient of z^0 after multiplying through by $(1 + z)$ gives

$$SD_0 = \sqrt{2}$$

The coefficients of z^k, $k \geq 1$ give:

$$2\,(SI_k - SI_{k-1}) = SD_k + SD_{k-1}$$

thus:

$$SD_k = -SD_{k-1} + 2\,(SI_k - SI_{k-1})$$

Program is:

```

Example D: "Expensive" Time Domain Technique for $Q_z = i \ell Q$ and Comparison to Analytic Green's Functions

The analytic Green's function (Morse & Feshbach, p. 894) is given by the statement function, G , and the "expensive" solution for the same one dimensional diffusion problem is given in the subroutine G 1. However, a direct compariosn is not possible (due to differences in definition for Green's function).

Thus we compare Feshbach's function, G_F , at $z = 2$ with the result of propagating Feshbach's function at $z= 1$ across the interval $z=1$ to $z=2$ by our method:

$$G_F\ (z=2) \ = \ [G_F(z=1)] * [G_1(z=1)]$$

where G_1 is our function. The comparison is good as shown by the example. Feshbach's function is defined such that

$$[\ G_F(z=1)\ ] * [\ G_F(z=1)\ ] \neq [\ G_F(z=2)\ ]$$

as we discovered by a numerical convolution and as undoubtedly can be verified theoretically.

Program:

```
1           DIMENSION T1(100),TN(100),P(100),PN(100),S1(100),SD(100)

Example F: "Expensive" Two Dimensional Time Domain Technique

The program uses equation (7) of section II. The comparison is similar to that for the one dimensional case. We compare Feshbach's Green's function, G_F, at $z = 2$ with the result of propagating G_F from $z = 1$ to $z = 2$ by our technique:

$$G_F\ (z=2) \;=\; [\ G_F\ (z=1)\ ] * [\ G\ (z=1)\ ] \qquad (1)$$

G_F is given in the statement function G 2 (z) . In the comparison, the left and right columns correspond to the left and right sides of the comparison above. The impulse is at the left side ; x axis to right, t axis down. The numbers along the top are degrees off vertical from the source impulse. The fairly good agreement up to 45° may be spurious in that there is a periodicity to the sources, i.e. for x_{max} on the right hand side there are sources at x=0 and at $x=4x_{max}$.

Example G: Program for Strong Contrast Techniques

Consider

$$B = B_x^{N\ \Delta z}_{\ \Delta x}$$

Then equation (4) of part III becomes:

$$\left(\frac{\sigma_z}{\sigma} - 2\,i\ell\right)\left(B_x^{N+1} - B_x^N\right) = \frac{\Delta z}{2\Delta x^2}\left[\left(B_{x+1} - 2B_x + B_{x-1}\right)^{N+1} + \left(B_{x+1} - 2B_x + B_{x-1}\right)^{N}\right]$$

$$- \frac{\Delta z}{4\Delta x}\left(\frac{\sigma_x}{\sigma}\right)\left[\left(B_{x+1} - B_{x-1}\right)^{N+1} + \left(B_{x+1} - B_{x-1}\right)^{N}\right] + \frac{\Delta z}{2}\left(\ell^2 + \bar{\ell}^2\right)\left(B_x^N + B_x^{N+1}\right)$$

Rearranging

$$B_{x-1}^{N+1}\left[-\frac{\Delta z}{2\Delta x^2} - \frac{\Delta z}{4\Delta x}\frac{\sigma_x}{\sigma}\right]$$

$$+ \quad B_x^{N+1}\left[\frac{\sigma_z}{\sigma} - 2i\bar{\ell} + \frac{\Delta z}{\Delta x^2} - \frac{\Delta z}{2}\left(\ell^2 + \bar{\ell}^2\right)\right]$$

$$+ \quad B_{x+1}^{N+1}\left[-\frac{\Delta z}{2\Delta x^2} + \frac{\Delta z}{4\Delta x}\frac{\sigma_x}{\sigma}\right]$$

$$= B_{x-1}^{N}\left[\frac{\Delta z}{2\Delta x^2} + \frac{\Delta z}{4\Delta x}\frac{\sigma_x}{\sigma}\right]$$

$$+ B_x^N\left[\frac{\sigma_z}{\sigma} - 2i\bar{\ell} - \frac{\Delta z}{\Delta x^2} + \frac{\Delta z}{2}\left(\ell^2 + \bar{\ell}^2\right)\right]$$

$$+ B_{x+1}^{N}\left[\frac{\Delta z}{2\Delta x^2} - \frac{\Delta z}{4\Delta x}\frac{\sigma_x}{\sigma}\right]$$

As done earlier (Example B) we also halve the secondary source terms since we have an equation for only one way propagation in z.; ℓ is also used in place of $\bar{\ell}$.

Example I : Program for Up and Down Going Propagation

To model upward and downward propagation, we first utilize the techniques of Example G for the downward propagation, then use equation (9) of Part III for the upward direction. The up-down sequence may be iterated.

Letting $B^{-} = B^{N\Delta z}_{x\Delta x}$, equation (9) of Part III is

$$\left(2i\bar{\ell} + \frac{\sigma_z}{\sigma} \right) \frac{\left(B^{N+1}_x - B^N_x \right)}{\Delta z} = \frac{\left(B^{N+1}_{x+1} + B^N_{x+1} - 2B^{N+1}_x - 2B^N_x + B^{N+1}_{x-1} + B^N_{x-1} \right.}{2\left(\Delta x \right)^2}$$

$$- \frac{\sigma_x}{\sigma} \left(\frac{B^{N+1}_{x+1} + B^N_{x+1} - B^{N+1}_{x-1} - B^N_{x-1}}{4\,\Delta x} \right) + 1/2\left(B^{N+1}_x + B^N_x \right)\left(\ell^2 + \bar{\ell}^2 \right)$$

$$+ \left(\frac{B^{*N+2}_x - B^{*N+1}_x - B^{*N}_x + B^{*N-1}_x}{2\left(\Delta z \right)^2} \right) - 2i\bar{\ell}\left(\frac{B^{*N+1}_x - B^{*N}_x}{\Delta z} \right) - \frac{\bar{\ell}^2}{2}\left(B^{*N+1}_x + B^{*N}_x \right)$$

where we write B^* for B^+

Rearranging:

$$B^N_{x-1}\left[- \frac{\Delta z}{2(\Delta x)^2} - \frac{\sigma_x}{\sigma}\frac{\Delta z}{4\Delta x} \right]$$

$$+ B^N_x\left[- 2i\bar{\ell} - \frac{\sigma_z}{\sigma} + \frac{\Delta z}{(\Delta x)^2} - \frac{\Delta z}{2}\left(\ell^2 + \bar{\ell}^2 \right) \right]$$

$$+ B^N_{x+1}\left[- \frac{\Delta z}{2(\Delta x)^2} + \frac{\sigma_x}{\sigma}\frac{\Delta z}{4\Delta z} \right]$$

$$= B^{N+1}_{x-1}\left[\frac{\Delta z}{2(\Delta x)^2} + \frac{\sigma_x}{\sigma}\frac{\Delta z}{4\Delta x} \right]$$

$$+ B^{N+1}_x\left[- 2i\bar{\ell} - \frac{\sigma_z}{\sigma} - \frac{\Delta z}{(\Delta x)^2} + \frac{\Delta z}{2}\left(\ell^2 + \bar{\ell}^2 \right) \right]$$

$$+ B^{N+1}_{x+1}\left[\frac{\Delta z}{2(\Delta x)^2} - \frac{\sigma_x}{\sigma}\frac{\Delta z}{4\Delta x} \right] + B^{*N+2}_x\left(\frac{1}{2(\Delta z)^2} \right)$$

$$+ \; B_x^{*N+1}\left(\frac{-1}{2(\Delta z)^2} - \frac{2i\bar{\ell}}{\Delta z} - \frac{\bar{\ell}^2}{2}\right) + B_x^{*N}\left(\frac{-1}{2(\Delta z)^2} + \frac{2i\bar{\ell}}{\Delta z} - \frac{\bar{\ell}^2}{2}\right) + B_x^{*N-1}\left(\frac{1}{2(\Delta z)^2}\right)$$

Again, we set all $\bar{\ell}$'s to ℓ. Also, the secondary source terms in σ_x and σ_z are halved: half upgoing, half downgoing.

The program is given along with a one dimensional problem of a horizontal layer. The conductivity contrast is 5 to 1; thus, there is a large reflection coefficient. The results aren't what we expect: what's the problem? First we note that the Fresnel approximation is not valid for this type of contrast. We start with $B = Q\, e^{i\bar{m}z}$ and drop Q_{zz} as small. If $\bar{m}$ is constant, then Q has to vary considerably in one or both of the mediums forming a strong contrast. However, we have used m rather than $\bar{m}$ in an equation for B that we got after transforming Q to B by $Q = B\, e^{-i\bar{m}z}$. This doesn't solve the problem here though.

When we estimate Q_{zz}^{+} to find the "source" terms for the upgoing wave our difference operator will be 3 levels in z and thus span across the contact. The desirable fact that Q was like a perturbation about e^{imz} rather than $e^{i\bar{m}z}$ is somewhat clouded by the way we do estimate Q_{zz}^{+}.

Thus, upgoing propagation requires "slowly" variable conductivity. In fact, for the large conductivity contrasts at the surface and possibly at some horizontal contact(s) we have to model multiples until amplitudes decay after several skin depths of propagation.

This is a rather basic problem: we are looking for a solution.
