

Intel® Math Kernel Library

Reference Manual

September 2007

Disclaimer and Legal Information

Document Number: 630813-027US

World Wide Web: <http://developer.intel.com>

Version	Version Information	Date
-001	Original Issue.	11/94
-002	Added functions crotg, zrotg. Documented versions of functions ?her2k, ?symm, ?syrk, and ?syr2k not previously described. Pagination revised.	5/95
-003	Changed the title; former title: "Intel BLAS Library for the Pentium® Processor Reference Manual." Added functions ?rotm, ?rotmg and updated Appendix C.	1/96
-004	Documents Intel® Math Kernel library (Intel® MKL) release 2.0 with the parallelism capability. Information on parallelism has been added in Chapter 1 and in section "BLAS Level 3 Routines" in Chapter 2.	11/96
-005	Two-dimensional FFTs have been added. C interface has been added to both one- and two-dimensional FFTs.	8/97
-006	Documents Intel Math Kernel Library release 2.1. Sparse BLAS section has been added in Chapter 2.	1/98
-007	Documents Intel Math Kernel Library release 3.0. Descriptions of LAPACK routines (Chapters 4 and 5) and CBLAS interface (Appendix C) have been added. Quick Reference has been excluded from the manual; MKL 3.0 Quick Reference is now available in HTML format.	1/99
-008	Documents Intel Math Kernel Library release 3.2. Description of FFT routines have been revised. In Chapters 4 and 5 NAG names for LAPACK routines have been excluded.	6/99
-009	New LAPACK routines for eigenvalue problems have been added in chapter 5.	11/99
-010	Documents Intel Math Kernel Library release 4.0. Chapter 6 describing the VML functions has been added.	06/00
-011	Documents Intel Math Kernel Library release 5.1. LAPACK section has been extended to include the full list of computational and driver routines.	04/01
-6001	Documents Intel Math Kernel Library release 6.0 beta. New DFT interface and Vector Statistical Library functions have been added.	07/02
-6002	Documents Intel Math Kernel Library 6.0 beta update. DFT functions description has been updated. CBLAS interface description was extended.	12/02
-6003	Documents Intel Math Kernel Library 6.0 gold. DFT functions have been updated. Auxiliary LAPACK routines' descriptions were added to the manual.	03/03
-6004	Documents Intel Math Kernel Library release 6.1.	07/03
-6005	Documents Intel Math Kernel Library release 7.0 beta. Includes ScaLAPACK and sparse solver descriptions.	11/03
-017	Documents Intel MKL and Intel® Cluster MKL release 7.0 gold. Auxiliary ScaLAPACK and alternative sparse solver interface were added.	04/04

Version	Version Information	Date
-018	Documents Intel MKL and Intel® Cluster MKL release 8.0 beta. Sparse BLAS and DFTI sections were extended. New functionality was added: Sparse BLAS, Cluster DFTI, iterative sparse solver, multiple-precision arithmetic, interval linear solver, and convolution/correlation. Fortran95 interface to LAPACK functions was added.	03/05
-019	Documents Intel MKL and Intel® Cluster MKL release 8.0 gold. Fortran95 interface to BLAS and Sparse BLAS functions has been added.	08/05
-020	Documents Intel MKL and Intel Cluster MKL release 8.0.2. PARDISO functionality description has been extended with indefinite symmetric matrices pivoting.	03/06
-021	Documents Intel MKL and Intel Cluster MKL release 8.1 gold. Chapter 13 on Trigonometric Transform functions has been added. Information on specific features of Fortran-95 implementation for LAPACK routines has been reflected in a new Appendix E and the relevant subsection of Chapter 3.	03/06
-022	Documents Intel MKL and Intel Cluster MKL release 9.0 beta. Statistical Functions, Fourier Transform Functions (Cluster DFT) descriptions have been updated. Description of new VML functions, RCI Sparse Solvers, and Poisson solver have been added. Chapter 13 has been renamed to PDE Support. Code examples have been expanded.	05/06
-023	Documents Intel MKL and Intel Cluster MKL release 9.0 gold. Complex Interval Solvers have been added. Description of the old deprecated FFT functions have been removed.	09/06
-024	Documents Intel MKL and Intel Cluster MKL release 9.1 beta. Optimization Solvers Routines and Support Functions chapters have been added. Chapters on Sparse Solvers and Partial Differential Equations Support have been extended. LAPACK chapters have been partially updated to reflect LAPACK 3.1 version.	01/07
-025	Documents Intel MKL and Intel Cluster MKL release 9.1 gold. BLACS chapter has been added. Chapters on BLAS and FFT have been extended. LAPACK chapters have been additionally updated to reflect LAPACK 3.1 version. Description of BSR format has been added to Appendix A. New FFT examples have been added to Appendix C.	03/07
-026	Documents Intel MKL and Intel Cluster MKL release 10.0 beta. BLACS, BLAS, Sparse Solver, VML, and FFT chapters have been extended. Description of new Threading Control functions has been added to Support Functions chapter.	07/07
-027	Documents Intel MKL release 10.0. BLAS, Sparse Solver, VML, and PDES chapters have been updated.	09/07

INFORMATION IN THIS DOCUMENT IS PROVIDED IN CONNECTION WITH INTEL® PRODUCTS. NO LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE, TO ANY INTELLECTUAL PROPERTY RIGHTS IS GRANTED BY THIS DOCUMENT. EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER, AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

UNLESS OTHERWISE AGREED IN WRITING BY INTEL, THE INTEL PRODUCTS ARE NOT DESIGNED NOR INTENDED FOR ANY APPLICATION IN WHICH THE FAILURE OF THE INTEL PRODUCT COULD CREATE A SITUATION WHERE PERSONAL INJURY OR DEATH MAY OCCUR.

Intel may make changes to specifications and product descriptions at any time, without notice. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. The information here is subject to change without notice. Do not finalize a design with this information.

The products described in this document may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

Copies of documents which have an order number and are referenced in this document, or other Intel literature, may be obtained by calling 1-800-548-4725, or by visiting Intel's Web Site. Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See http://www.intel.com/products/processor_number for details.

Chapter 8: Sparse Solver Routines

PARDISO* - Parallel Direct Sparse Solver Interface.....	2163
pardiso.....	2164
Direct Sparse Solver (DSS) Interface Routines.....	2182
DSS Interface Description.....	2184
dss_create.....	2186
dss_define_structure.....	2187
dss_reorder.....	2189
dss_factor_real, dss_factor_complex.....	2190
dss_solve_real, dss_solve_complex.....	2191
dss_delete.....	2192
dss_statistics.....	2193
mkl_cvt_to_null_terminated_str.....	2196
Implementation Details.....	2197
Iterative Sparse Solvers based on Reverse Communication Interface	
(RCI ISS).....	2198
CG Interface Description.....	2203
FGMRES Interface Description.....	2209
dcg_init.....	2218
dcg_check.....	2219
dcg.....	2221
dcg_get.....	2223
dcgmrhs_init.....	2224
dcgmrhs_check.....	2225
dcgmrhs.....	2227
dcgmrhs_get.....	2229
dfgmres_init.....	2230
dfgmres_check.....	2231
dfgmres.....	2233
dfgmres_get.....	2235
Implementation Details.....	2237
Preconditioners based on Incomplete LU Factorization Technique...	2238
ILU0 and ILUT Preconditioners Interface Description.....	2241

dcscrilu0.....	2242
dcscrilut.....	2247
Calling Sparse Solver and Preconditioner Routines from C/C++.....	2252

Chapter 9: Vector Mathematical Functions

Data Types and Accuracy Modes.....	2255
Function Naming Conventions.....	2256
Functions Interface.....	2257
VML Mathematical Functions.....	2257
Pack Functions.....	2257
Unpack Functions.....	2257
Service Functions.....	2258
Input Parameters.....	2258
Output Parameters.....	2259
Vector Indexing Methods.....	2259
Error Diagnostics.....	2260
VML Mathematical Functions.....	2260
Arithmetic Functions.....	2263
Add.....	2263
Sub.....	2265
Sqr.....	2266
Mul.....	2268
MulByConj.....	2269
Conj.....	2271
Abs.....	2272
Power and Root Functions.....	2274

Routines for Checking Properties of Interval Matrices.....	2625
?gerbr.....	2625
?gesvr.....	2627
Auxiliary and Utility Routines.....	2630
?gemip.....	2630

Chapter 13: Partial Differential Equations Support

Trigonometric Transform Routines.....	2633
Transforms Implemented.....	2634
Sequence of Invoking TT Routines.....	2636
Interface Description.....	2639
TT Routines.....	2640
?_init_trig_transform.....	2640

?_commit_trig_transform.....	2641
?_forward_trig_transform.....	2644
?_backward_trig_transform.....	2646
free_trig_transform.....	2648
Common Parameters.....	2649
Implementation Details.....	2654
Poisson Library Routines	2657
Poisson Library Implemented.....	2658
Sequence of Invoking PL Routines.....	2666
Interface Description.....	2669
PL Routines for the Cartesian Solver.....	2670
?_init_Helmholtz_2D/?_init_Helmholtz_3D.....	2670
?_commit_Helmholtz_2D/?_commit_Helmholtz_3D....	2673
?_Helmholtz_2D/?_Helmholtz_3D.....	2679
free_Helmholtz_2D/free_Helmholtz_3D.....	2685
PL Routines for the Spherical Solver.....	2686
?_init_sph_p/?_init_sph_np.....	2686
?_commit_sph_p/?_commit_sph_np.....	2689
?_sph_p/?_sph_np.....	2691
free_sph_p/free_sph_np.....	2694
Common Parameters.....	2695
Implementation Details.....	2704
Calling PDE Support Routines from Fortran 90.....	2717

Chapter 14: Optimization Solver Routines

Organization and Implementation.....	2721
Nonlinear Least Squares Problem without Constraints.....	2723
dtrnlsp_init.....	2724
dtrnlsp_solve.....	2725
dtrnlsp_get.....	2727
dtrnlsp_delete.....	2729
Examples of dtrnlsp Usage.....	2730

Nonlinear Least Squares Problem with Linear (Bound) Constraints..	2743
dtrnlspbc_init.....	2744
dtrnlspbc_solve.....	2746
dtrnlspbc_get.....	2747
dtrnlspbc_delete.....	2749
Examples of dtrnlspbc Usage.....	2750
Jacobi Matrix Calculation Routines.....	2765
djacobi_init.....	2766
djacobi_solve.....	2767
djacobi_delete.....	2768
djacobi.....	2768
Examples of djacobi_solve Usage.....	2770
Examples of djacobi Usage.....	2777

Chapter 15: Support Functions

Version Information Functions.....	2783
MKLGetVersion.....	2783
MKLGetVersionString.....	2785
Threading Control Functions.....	2787
mkl_set_num_threads.....	2788
mkl_domain_set_num_threads.....	2788
mkl_set_dynamic.....	2789
mkl_get_max_threads.....	2790
mkl_domain_get_max_threads.....	2791
mkl_get_dynamic.....	2792
Error Handling Functions.....	2793
xerbla.....	2793
pxerbla.....	2793
Equality Test Functions.....	2794
lsame.....	2794
lsamen.....	2795
Timing Functions.....	2796

second/dsecnd.....	2796
getcpuclocks.....	2796
getcpufrequency.....	2797
setcpufrequency.....	2797
Memory Functions.....	2798
MKL_FreeBuffers.....	2798
MKL_MemStat.....	2800
MKL_malloc.....	2801
MKL_free.....	2802
Examples of MKL_malloc(), MKL_free(), MKL_MemStat() Usage.....	2803

Chapter 16: BLACS Routines

Matrix Shapes.....	2807
BLACS Combine Operations.....	2808
?gamx2d.....	2810
?gamn2d.....	2812
?gsum2d.....	2814
BLACS Point To Point Communication.....	2815
?gesd2d.....	2818
?trsd2d.....	2819
?gerv2d.....	2820
?trrv2d.....	2821
BLACS Broadcast Routines.....	2822
?gebs2d.....	2823
?trbs2d.....	2824
?gebr2d.....	2825
?trbr2d.....	2826
BLACS Support Routines.....	2827
Initialization Routines.....	2827
blacs_pinfo.....	2828
blacs_setup.....	2828

blacs_get.....	2830
blacs_set.....	2831
blacs_gridinit.....	2832
blacs_gridmap.....	2834
Destruction Routines.....	2835
blacs_freebuff.....	2836
blacs_gridexit.....	2836
blacs_abort.....	2837
blacs_exit.....	2837
Informational Routines.....	2838
blacs_gridinfo.....	2838
blacs_pnum.....	2839
blacs_pcoord.....	2840
Miscellaneous Routines.....	2840
blacs_barrier.....	2841
Examples of BLACS Routines Usage.....	2842

Appendix A: Linear Solvers Basics

Sparse Linear Systems.....	2861
Matrix Fundamentals.....	2862
Direct Method.....	2863
Sparse Matrix Storage Formats.....	2869
Interval Linear Systems.....	2883
Intervals.....	2883
Interval vectors and matrices.....	2885
Preconditioning.....	2890
Inverting interval matrices.....	2890

Appendix B: Routine and Function Arguments

Vector Arguments in BLAS.....	2893
Vector Arguments in VML.....	2894

Matrix Arguments.....	2895

Appendix C: Code Examples

BLAS Code Examples.....	2901
PARDISO Code Examples.....	2908
Examples for Sparse Symmetric Linear Systems.....	2909
Examples for Sparse Unsymmetric Linear Systems.....	2921
Direct Sparse Solver Code Examples.....	2935
Iterative Sparse Solver Code Examples.....	2949
Fourier Transform Functions Code Examples.....	2997
FFT Code Examples.....	2997
Examples of Using Multi-Threading for FFT Computation.....	3016
Examples for Cluster FFT Functions.....	3022
Auxiliary Data Transformations.....	3026
Interval Linear Solvers Code Examples.....	3029
PDE Support Code Examples.....	3041
Trigonometric Transforms Interface Code Examples.....	3041
Poisson Library Code Examples.....	3060
Preconditioner Code Examples.....	3091

Appendix D: CBLAS Interface to the BLAS

CBLAS Arguments.....	3159
Level 1 CBLAS.....	3160
Level 2 CBLAS.....	3164
Level 3 CBLAS.....	3172
Sparse CBLAS.....	3175

Appendix E: Specific Features of Fortran 95 Interfaces for LAPACK Routines

Interfaces Identical to Netlib.....	3180

Interfaces with Replaced Argument Names.....3183

Modified Netlib Interfaces.....3185

Interfaces Absent From Netlib.....3187

Interfaces of New Functionality.....3193

Overview

The Intel® Math Kernel Library (Intel® MKL) provides Fortran routines and functions that perform a wide variety of operations on vectors and matrices including sparse matrices and interval matrices. The library also includes fast Fourier transform (FFT) functions, as well as vector mathematical and vector statistical functions with Fortran and C interfaces.

The versions of Intel MKL intended for Windows* and Linux* operating systems also include ScaLAPACK software and Cluster FFT software for solving respective computational problems on distributed-memory parallel computers.

The Intel MKL enhances performance of the application programs that use it because the library has been optimized for latest generations of Intel® processors.

This chapter introduces the Intel Math Kernel Library and provides information about the organization of this manual.

About This Software

The Intel® Math Kernel Library includes the following groups of routines:

- Basic Linear Algebra Subprograms (BLAS):
 - vector operations
 - matrix-vector operations
 - matrix-matrix operations
- Sparse BLAS Level 1, 2, and 3 (basic operations on sparse vectors and matrices)
- LAPACK routines for solving systems of linear equations
- LAPACK routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations
- Auxiliary and utility LAPACK routines
- ScaLAPACK computational, driver and auxiliary routines (only in Intel MKL for Linux* and Windows* operating systems)
- Direct and Iterative Sparse Solver routines
- Vector Mathematical Library (VML) functions for computing core mathematical functions on vector arguments (with Fortran and C interfaces)

- Vector Statistical Library (VSL) functions for generating vectors of pseudorandom numbers with different types of statistical distributions and for performing convolution and correlation computations
- General Fast Fourier Transform (FFT) Functions, providing fast computation of Discrete Fourier Transform via the FFT algorithms and having Fortran and C interfaces
- Cluster FFT functions (only in Intel MKL for Linux* and Windows* operating systems)
- Interval Solver routines for solving systems of interval linear equations
- Tools for solving partial differential equations - trigonometric transform routines and Poisson solver
- Optimization Solver routines for solving nonlinear least squares problems through the Trust-Region (TR) algorithms and computing Jacobi matrix by central differences
- Basic Linear Algebra Communication Subprograms (BLACS) that are used to support a linear algebra oriented message passing interface.
- GMP arithmetic functions

For specific issues on using the library, please refer to the *MKL Release Notes*.

Technical Support

Intel MKL provides a product web site that offers timely and comprehensive product information, including product features, white papers, and technical articles. For the latest information, check: <http://developer.intel.com/software/products/>

Intel also provides a support web site that contains a rich repository of self help information, including getting started tips, known product issues, product errata, license information, user forums, and more (visit <http://support.intel.com/support/performance/tools/libraries/mkl>).

Registering your product entitles you to one year of technical support and product updates through Intel® Premier Support. Intel Premier Support is an interactive issue management and communication web site providing these services:

- Submit issues and review their status.
- Download product updates anytime of the day.

To register your product, contact Intel, or seek product support, please visit: <http://developer.intel.com/software/products/support>.

BLAS Routines

The BLAS routines and functions are divided into the following groups according to the operations they perform:

- [BLAS Level 1 Routines and Functions](#) perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
- [BLAS Level 2 Routines](#) perform matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
- [BLAS Level 3 Routines](#) perform matrix-matrix operations, such as matrix-matrix multiplication, rank-k update, and solution of triangular systems.

Starting from release 8.0, Intel® MKL also supports Fortran 95 interface to the BLAS routines.

Sparse BLAS Routines

The [Sparse BLAS Level 1 Routines and Functions](#) and [Sparse BLAS Level 2 Routines and Level 3 routines](#) and functions operate on sparse vectors and matrices. These routines perform vector operations similar to the BLAS Level 1, 2, and 3 routines. The Sparse BLAS routines take advantage of vector and matrix sparsity: they allow you to store only non-zero elements of vectors and matrices. Intel MKL also supports Fortran 95 interface to Sparse BLAS routines.

LAPACK Routines

The Intel® Math Kernel Library fully supports LAPACK 3.1 set of computational, driver, auxiliary and utility routines.

The original versions of LAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/lapack/index.html>. The authors of LAPACK are E. Anderson, Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen.

The LAPACK routines can be divided into the following groups according to the operations they perform:

- Routines for solving systems of linear equations, factoring and inverting matrices, and estimating condition numbers (see [Chapter 3](#)).
- Routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations (see [Chapter 4](#)).
- Auxiliary and utility routines used to perform certain subtasks, common low-level computation or related tasks (see [Chapter 5](#)).

Starting from release 8.0, Intel MKL also supports Fortran-95 interface to LAPACK computational and driver routines. This interface provides an opportunity for simplified calls of LAPACK routines with fewer required arguments.

ScaLAPACK Routines

The ScaLAPACK package (included only with the Intel® MKL versions for Linux* and Windows* operating systems, see [Chapter 6](#) and [Chapter 7](#)) runs on distributed-memory architectures and includes routines for solving systems of linear equations, solving linear least squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

The original versions of ScaLAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/scalapack/index.html>. The authors of ScaLAPACK are L. Blackford, J. Choi, A. Cleary, E. D'Azevedo, J. Demmel, I. Dhillon, J. Dongarra, S. Hammarling, G. Henry, A. Petitet, K. Stanley, D. Walker, and R. Whaley.

The Intel MKL version of ScaLAPACK is optimized for Intel® processors and uses MPICH version of MPI as well as Intel MPI.

Sparse Solver Routines

Direct sparse solver routines in Intel MKL (see [Chapter 8](#)) solve symmetric and symmetrically-structured sparse matrices with real or complex coefficients. For symmetric matrices, these Intel MKL subroutines can solve both positive-definite and indefinite systems. Intel MKL includes the PARDISO* sparse solver interface as well as an alternative set of user callable direct sparse solver routines.

If you use the sparse solver PARDISO* from Intel MKL, please cite:

O.Schenk and K.Gärtner. Solving unsymmetric sparse systems of linear equations with PARDISO. J. of Future Generation Computer Systems, 20(3):475-487, 2004.

Intel MKL provides also an iterative sparse solver (see [Chapter 8](#)) that uses Sparse BLAS level 2 and 3 routines and works with different sparse data formats.

VML Functions

The Vector Mathematical Library (VML) functions (see [Chapter 9](#)) include a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic, etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VML include nonlinear programming software, integrals computation, and many others. VML provides interfaces both for Fortran and C languages.

Statistical Functions

The Vector Statistical Library (VSL) contains two sets of functions (see [Chapter 10](#)):

- The first set includes a collection of pseudo- and quasi-random number generator subroutines implementing basic continuous and discrete distributions. To provide best performance, the VSL subroutines use calls to highly optimized Basic Random Number Generators (BRNGs) and a library of vector mathematical functions.
- The second set includes a collection of routines that implement a wide variety of convolution and correlation operations.

Fourier Transform Functions

The Intel® MKL multidimensional Fast Fourier Transform (FFT) functions with mixed radix support (see [Chapter 11](#)) provide uniformity of discrete Fourier transform computation and combine functionality with ease of use. Both Fortran and C interface specification are given. There is also a cluster version of FFT functions, which runs on distributed-memory architectures and is provided only in Intel MKL versions for the Linux* and Windows* operating systems.

The FFT functions provide fast computation via the FFT algorithms not only for lengths that are powers of 2 but also for 3, 5, 7, 11, and other radices.

Interval Solver Routines

Interval Solver routines included into Intel® MKL (see [Chapter 12](#)) can be used to solve interval systems of linear equations and related problems.

Partial Differential Equations Support

Intel® MKL provides tools for solving Partial Differential Equations (PDE) (see [Chapter 13](#)). These tools are Trigonometric Transform interface routines and Poisson Library.

The Trigonometric Transform routines may be helpful to users who implement their own solvers similar to the solver that the Poisson Library provides. The users can improve performance of their solvers by using fast sine, cosine, and staggered cosine transforms implemented in the Trigonometric Transform interface.

The Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The Trigonometric Transform interface, which underlies the solver, is based on the Intel MKL FFT interface (refer to [Chapter 11](#)), optimized for Intel® processors.

Optimization Solver Routines

Intel® MKL provides Optimization Solver routines (see [Chapter 14](#)) that can be used to solve nonlinear least squares problems with or without linear (bound) constraints through the Trust-Region (TR) algorithms and compute Jacobi matrix by central differences.

See also Appendix A [Optimization Solvers Basics](#) for description of the basic notions of optimization solvers, nonlinear least square problems, and the TR algorithm.

Support Functions

The Intel® MKL support functions (see [Chapter 15](#)) are used to support the operation of the Intel MKL software and provide basic information on the library and library operation, such as the current library version, timing, setting and measuring of CPU frequency, error handling, and memory allocation.

Starting from 10.0 version, the Intel MKL support functions provide additional threading control.

BLACS Routines

The Intel® Math Kernel Library implements routines from the BLACS (Basic Linear Algebra Communication Subprograms) package (see [Chapter 16](#)) that are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The original versions of BLACS from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/blacs/index.html>. The authors of BLACS are Jack Dongarra and R. Clint Whaley.

GMP Arithmetic Functions

Intel® MKL implementation of GMP arithmetic functions includes arbitrary precision arithmetic operations on integer numbers. The interfaces of such functions fully match the GNU Multiple Precision (GMP) Arithmetic Library.

Performance Enhancements

The Intel® Math Kernel Library has been optimized by exploiting both processor and system features and capabilities. Special care has been given to those routines that most profit from cache-management techniques. These especially include matrix-matrix operation routines such as `dgemm()`.

In addition, code optimization techniques have been applied to minimize dependencies of scheduling integer and floating-point units on the results within the processor.

The major optimization techniques used throughout the library include:

- Loop unrolling to minimize loop management costs
- Blocking of data to improve data reuse opportunities
- Copying to reduce chances of data eviction from cache
- Data prefetching to help hide memory latency
- Multiple simultaneous operations (for example, dot products in `dgemm`) to eliminate stalls due to arithmetic unit pipelines
- Use of hardware features such as the SIMD arithmetic units, where appropriate

These are techniques from which the arithmetic code benefits the most.

Parallelism

In addition to the performance enhancements discussed above, Intel® MKL offers performance gains through parallelism provided by the symmetric multiprocessing performance (SMP) feature. You can obtain improvements from SMP in the following ways:

- One way is based on user-managed threads in the program and further distribution of the operations over the threads based on data decomposition, domain decomposition, control decomposition, or some other parallelizing technique. Each thread can use any of the Intel MKL functions because the library has been designed to be thread-safe.
- Another method is to use the FFT and BLAS level 3 routines. They have been parallelized and require no alterations of your application to gain the performance enhancements of multiprocessing. Performance using multiple processors on the level 3 BLAS shows excellent scaling. Since the threads are called and managed within the library, the application does not need to be recompiled thread-safe (see also [Fortran 95 Interface Conventions](#) in Chapter 2).

- Yet another method is to use *tuned LAPACK routines*. Currently these include the single- and double precision flavors of routines for *QR* factorization of general matrices, triangular factorization of general and symmetric positive-definite matrices, solving systems of equations with such matrices, as well as solving symmetric eigenvalue problems.

For instructions on setting the number of available processors for the BLAS level 3 and LAPACK routines, see *Intel® MKL User's Guide*.

Platforms Supported

The Intel® Math Kernel Library includes Fortran routines and functions optimized for Intel® processor-based computers running operating systems that support multiprocessing. In addition to the Fortran interface, Intel MKL includes a C-language interface for the Discrete Fourier transform functions, as well as for the Vector Mathematical Library and Vector Statistical Library functions. For hardware and software requirements to use Intel MKL, see *Intel® MKL Release Notes*.

About This Manual

This manual describes the routines and functions of Intel® MKL. Each reference section describes a routine group typically consisting of routines used with four basic data types: single-precision real, double-precision real, single-precision complex, and double-precision complex.

Each routine group is introduced by its name, a short description of its purpose, and the calling sequence, or syntax, for each type of data with which each routine of the group is used. The following sections are also included:

Description	Describes the operation performed by routines of the group based on one or more equations. The data types of the arguments are defined in general terms for the group.
Input Parameters	Defines the data type for each parameter on entry, for example: a REAL for saxpy DOUBLE PRECISION for daxpy
Output Parameters	Lists resultant parameters on exit.

The following terms are used in the manual in reference to various operating systems:

Windows* OS	This term refers to information that is valid on all supported Microsoft Windows* operating systems.
Linux* OS	This term refers to information that is valid on all supported Linux* operating systems.

Mac OS* X This term refers to information that is valid on Intel®-based systems running the Mac OS* X operating system.

Audience for This Manual

The manual addresses programmers proficient in computational mathematics and assumes a working knowledge of the principles and vocabulary of linear algebra, mathematical statistics, and Fourier transforms.

Manual Organization

The manual contains the following chapters and appendixes:

Chapter 1	Overview . Introduces the Intel Math Kernel Library software, provides information on manual organization, and explains notational conventions.
Chapter 2	BLAS and Sparse BLAS Routines . Provides descriptions of BLAS and Sparse BLAS functions and routines.
Chapter 3	LAPACK Routines: Linear Equations . Provides descriptions of LAPACK routines for solving systems of linear equations and performing a number of related computational tasks: triangular factorization, matrix inversion, estimating the condition number of matrices.
Chapter 4	LAPACK Routines: Least Squares and Eigenvalue Problems . Provides descriptions of LAPACK routines for solving least squares problems, standard and generalized eigenvalue problems, singular value problems, and Sylvester's equations.
Chapter 5	LAPACK Auxiliary and Utility Routines . Describes auxiliary and utility LAPACK routines that perform certain subtasks or common low-level computation.
Chapter 6	ScaLAPACK Routines . Describes ScaLAPACK computational and driver routines (software included only with Intel MKL for Linux* and Windows* operating systems).
Chapter 7	ScaLAPACK Auxiliary and Utility Routines . Describes ScaLAPACK auxiliary routines (software included only with Intel MKL for Linux* and Windows* operating systems).
Chapter 8	Sparse Solver Routines . Describes direct sparse solver routines that solve symmetric and symmetrically-structured sparse matrices. Also describes the iterative sparse solver routines.
Chapter 9	Vector Mathematical Functions . Provides descriptions of VML functions for computing elementary mathematical functions on vector arguments.

Chapter 10	Statistical Functions . Provides descriptions of VSL functions for generating vectors of pseudorandom numbers and for performing convolution and correlation operations.
Chapter 11	Fourier Transform Functions . Describes multidimensional functions for computing fast Fourier transform and cluster FFT functions (software included only with Intel MKL for the Linux* and Windows* operating systems).
Chapter 12	Interval Linear Solvers . Describes routines that can be used to solve interval systems of linear equations and related problems.
Chapter 13	Partial Differential Equations Support . Describes Trigonometric Transform interface routines and Poisson Library implemented for solving Partial Differential Equations (PDE).
Chapter 14	Optimization Solver Routines . Describes routines for solving optimization problems. These routines solve nonlinear least squares problems through the Trust-Region (TR) algorithms and compute Jacobi matrix by central differences.
Chapter 15	Support Functions . Describes functions that are used to support the operation of Intel MKL software, such as status information functions, timing and error handling functions.
Chapter 16	BLACS Routines . Describes Basic Linear Algebra Communication Subprograms that are used to support a linear algebra oriented message passing interface.
Appendix A	Linear Solvers Basics . Briefly describes the basic definitions and approaches used in linear algebra for solving systems of linear equations. Describes sparse data storage formats, as well as basic concepts of interval arithmetic.
Appendix B	Routine and Function Arguments . Describes the major arguments of the BLAS routines and VML functions: vector and matrix arguments.
Appendix C	Code Examples . Provides code examples of calling various Intel MKL functions and routines (BLAS, PARDISO, Direct and Iterative Sparse Solver, FFT, Cluster FFT, Interval Linear Solvers, Trigonometric Transforms, and Poisson Library).
Appendix D	CBLAS Interface to the BLAS . Provides the C interface to the BLAS.
Appendix E	Specific Features of Fortran 95 Interfaces for LAPACK Routines . Provides the features of Intel MKL Fortran 95 interfaces for LAPACK routines in comparison with Netlib implementation.
Appendix F	Optimization Solvers Basics . Briefly describes the basic notions of optimization solvers, nonlinear least square problem, and Trust Region algorithm.

The manual also includes a [Bibliography](#), [Glossary](#) and an [Index](#).

Notational Conventions

This manual uses the following notational conventions:

- Routine name shorthand (for example, `?ungqr` instead of `cungqr/zungqr`).
- Font conventions used for distinction between the text and the code.

Routine Name Shorthand

For shorthand, names with a question mark “?” in them represent groups of routines with similar functionality. The question mark is used to indicate any or all possible varieties of a function; for example:

`?swap` Refers to all four data types of the vector-vector `?swap` routine: `sswap`, `dswap`, `cswap`, and `zswap`.

Font Conventions

The following font conventions are used:

<code>UPPERCASE COURIER</code>	Data type used in the description of input and output parameters for Fortran interface. For example, <code>CHARACTER*1</code> .
<code>lowercase courier</code>	Code examples: <code>a(k+i,j) = matrix(i,j)</code> and data types for C interface, for example, <code>const float*</code>
<code>lowercase courier</code> <code>mixed with UpperCase</code> <code>courier</code>	Function names for C interface, for example, <code>vmlSetMode</code>
<i>lowercase courier</i> <i>italic</i>	Variables in arguments and parameters description. For example, <i>incx</i> .
*	Used as a multiplication symbol in code examples and equations and where required by the Fortran syntax.

BLAS and Sparse BLAS Routines

2

This chapter contains descriptions of the BLAS and Sparse BLAS routines of the Intel® Math Kernel Library. The routine descriptions are arranged in several sections according to the BLAS level of operation:

- [BLAS Level 1 Routines](#) (vector-vector operations)
- [BLAS Level 2 Routines](#) (matrix-vector operations)
- [BLAS Level 3 Routines](#) (matrix-matrix operations)
- [Sparse BLAS Level 1 Routines](#) (vector-vector operations).
- [Sparse BLAS Level 2 and Level 3 Routines](#) (matrix-vector and matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by routine or function group name; for example, the `?asum` group, the `?axpy` group. The question mark in the group name corresponds to different character codes indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

When BLAS or Sparse BLAS routines encounter an error, they call the error reporting routine `xerbla`.

In BLAS Level 1 groups `i?amax` and `i?amin`, an “i” is placed before the character code and corresponds to the index of an element in the vector. These groups are placed in the end of the BLAS Level 1 section.

BLAS Routines

Routine Naming Conventions

BLAS routine names have the following structure:

`<character> <name> <mod> ( )`

The `<character>` field indicates the data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `scasum` uses a complex input array and returns a real value.

The `<name>` field, in BLAS level 1, indicates the operation type. For example, the BLAS level 1 routines `?dot`, `?rot`, `?swap` compute a vector dot product, vector rotation, and vector swap, respectively.

In BLAS level 2 and 3, `<name>` reflects the matrix argument type:

<code>ge</code>	general matrix
<code>gb</code>	general band matrix
<code>sy</code>	symmetric matrix
<code>sp</code>	symmetric matrix (packed storage)
<code>sb</code>	symmetric band matrix
<code>he</code>	Hermitian matrix
<code>hp</code>	Hermitian matrix (packed storage)
<code>hb</code>	Hermitian band matrix
<code>tr</code>	triangular matrix
<code>tp</code>	triangular matrix (packed storage)
<code>tb</code>	triangular band matrix.

The `<mod>` field, if present, provides additional details of the operation. BLAS level 1 names can have the following characters in the `<mod>` field:

<code>c</code>	conjugated vector
<code>u</code>	unconjugated vector
<code>g</code>	Givens rotation.

BLAS level 2 names can have the following characters in the `<mod>` field:

<code>mv</code>	matrix-vector product
<code>sv</code>	solving a system of linear equations with matrix-vector operations
<code>r</code>	rank-1 update of a matrix
<code>r2</code>	rank-2 update of a matrix.

BLAS level 3 names can have the following characters in the `<mod>` field:

<code>mm</code>	matrix-matrix product
<code>sm</code>	solving a system of linear equations with matrix-matrix operations
<code>rk</code>	rank- k update of a matrix
<code>r2k</code>	rank- $2k$ update of a matrix.

The examples below illustrate how to interpret BLAS routine names:

<code>ddot</code>	<code><d> <dot></code> : double-precision real vector-vector dot product

<code>cdotc</code>	<code><c> <dot> <c></code> : complex vector-vector dot product, conjugated
<code>scasum</code>	<code><sc> <asum></code> : sum of magnitudes of vector elements, single precision real output and single precision complex input
<code>cdotu</code>	<code><c> <dot> <u></code> : vector-vector dot product, unconjugated, complex
<code>sgemv</code>	<code><s> <ge> <mv></code> : matrix-vector product, general matrix, single precision
<code>ztrmm</code>	<code><z> <tr> <mm></code> : matrix-matrix product, triangular matrix, double-precision complex.

Sparse BLAS level 1 naming conventions are similar to those of BLAS level 1. For more information, see [“Naming Conventions”](#).

Fortran 95 Interface Conventions

Fortran 95 interface to BLAS and Sparse BLAS Level 1 routines is implemented through wrappers that call respective FORTRAN 77 routines. This interface uses such features of Fortran 95 as assumed-shape arrays and optional arguments to provide simplified calls to BLAS and Sparse BLAS Level 1 routines with fewer parameters.

NOTE. For BLAS, Intel MKL offers two types of Fortran 95 interfaces:

- using `mkl_blas.fi` only through `include 'mkl_blas_subroutine.fi'` statement. Such interfaces allow you to make use of the original LAPACK routines with all their arguments
 - using `mkl_blas.f90` that includes improved interfaces described below. This file is used to generate the module files `mkl95_blas.mod` and `mkl95_precision.mod`. See also section “Fortran 95 interfaces and wrappers to LAPACK and BLAS” of *Intel® MKL User's Guide* for details. The module files are used to process the FORTRAN use clauses referencing the LAPACK interface: `use mkl95_blas` and `use mkl95_precision`.
-

The main conventions used in Fortran 95 interface are as follows:

- The names of parameters used in Fortran 95 interface are typically the same as those used for the respective generic (FORTRAN 77) interface. However, certain changes of some parameter names are made to reduce their number in the whole library. For BLAS and Sparse BLAS Level 1 routines only one generic parameter name `ap` is changed to `a` in the Fortran 95 interface.

Note that these changes of the formal parameter names have no impact on program semantics and follow the conventions of names unification.

- Some input parameters such as array dimensions are not required in Fortran 95 and are skipped from the calling sequence. Array dimensions are reconstructed from the user data that must exactly follow the required array shape.
- A parameter can be skipped if its value is completely defined by the presence or absence of another parameter in the calling sequence, and the restored value is the only meaningful value for the skipped parameter.
- Parameters specifying the increment values *incx* and *incy* are skipped. In most cases their values are equal to 1. In Fortran 95 an increment with different value can be directly established in the corresponding parameter.
- Some generic parameters are declared as optional in Fortran 95 interface and may or may not be present in the calling sequence. A parameter can be declared optional if it satisfies one of the following conditions:
 1. It can take only a few possible values. The default value of such parameter typically is the first value in the list; all exceptions to this rule are explicitly stated in the routine description.
 2. It has a natural default value.

Optional parameters are given in square brackets in Fortran 95 call syntax.

The particular rules used for reconstructing the values of omitted optional parameters are specific for each routine and are detailed in the respective "Fortran 95 Notes" subsection at the end of routine specification section. If this subsection is omitted, the Fortran 95 interface for the given routine does not differ from the corresponding FORTRAN 77 interface.

Note that this interface is not implemented in the current version of Sparse BLAS Level 2 and Level 3 routines. Fortran 95 interface for each of these routines is given in the "Interfaces - Fortran 95" subsection at the end of the respective routine specification section.

Matrix Storage Schemes

Matrix arguments of BLAS routines can use the following storage schemes:

- *Full storage*: a matrix *A* is stored in a two-dimensional array *a*, with the matrix element a_{ij} stored in the array element $a(i, j)$.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: a band matrix is stored compactly in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

For more information on matrix storage schemes, see “[Matrix Arguments](#)” in Appendix B.

BLAS Level 1 Routines

BLAS Level 1 includes routines and functions, which perform vector-vector operations. [Table 2-1](#) lists the BLAS Level 1 routine and function groups and the data types associated with them.

Table 2-1 BLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
?asum	s, d, sc, dz	Sum of vector magnitudes (functions)
?axpy	s, d, c, z	Scalar-vector product (routines)
?copy	s, d, c, z	Copy vector (routines)
?dot	s, d	Dot product (functions)
?sdot	sd, d	Dot product with extended precision (functions)
?dotc	c, z	Dot product conjugated (functions)
?dotu	c, z	Dot product unconjugated (functions)
?nrm2	s, d, sc, dz	Vector 2-norm (Euclidean norm) (functions)
?rot	s, d, cs, zd	Plane rotation of points (routines)
?rotg	s, d, c, z	Givens rotation of points (routines)
?rotm	s, d	Modified plane rotation of points
?rotmg	s, d	Givens modified plane rotation of points
?scal	s, d, c, z, cs, zd	Vector scaling (routines)
?swap	s, d, c, z	Vector-vector swap (routines)
i?amax	s, d, c, z	Index of the maximum absolute value element of a vector (functions)

Routine or Function Group	Data Types	Description
<code>i?amin</code>	s, d, c, z	Index of the minimum absolute value element of a vector (functions)
<code>dcabs1</code>	d	Absolute value of a double precision complex number

?asum

Computes the sum of magnitudes of the vector elements.

Syntax

FORTRAN 77:

```
res = sasum(n, x, incx)
res = scasum(n, x, incx)
res = dasum(n, x, incx)
res = dzasum(n, x, incx)
```

Fortran 95:

```
res = asum(x)
```

Description

The function `?asum` function computes the sum of the magnitudes of elements of a real vector, or the sum of magnitudes of the real and imaginary parts of elements of a complex vector:

$$res = |Re\ x(1)| + |Im\ x(1)| + |Re\ x(2)| + |Im\ x(2)| + \dots + |Re\ x(n)| + |Im\ x(n)|,$$

where x is a vector of order n .

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
x	REAL for <code>sasum</code> DOUBLE PRECISION for <code>dasum</code> COMPLEX for <code>scasum</code> DOUBLE COMPLEX for <code>dzasum</code>

incx Array, DIMENSION at least $(1 + (n-1) * \text{abs}(incx))$.
 INTEGER. Specifies the increment for indexing vector *x*.

Output Parameters

res REAL for sasum
 DOUBLE PRECISION for dasum
 REAL for scasum
 DOUBLE PRECISION for dzasum
 Contains the sum of magnitudes of real and imaginary parts
 of all elements of the vector.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `asum` interface are the following:

x Holds the array of size(*n*).

?axpy

Computes a vector-scalar product and adds the result to a vector.

Syntax

FORTRAN 77:

```
call saxpy(n, a, x, incx, y, incy)
call daxpy(n, a, x, incx, y, incy)
call caxpy(n, a, x, incx, y, incy)
call zaxpy(n, a, x, incx, y, incy)
```

Fortran 95:

```
call axpy(x, y [,a])
```

Description

The `?axpy` routines perform a vector-vector operation defined as

$$y := a * x + y$$

where:

a is a scalar

x and y are vectors of order n .

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
a	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Specifies the scalar a .
x	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$.
incx	INTEGER. Specifies the increment for the elements of x .
y	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incy}))$.
incy	INTEGER. Specifies the increment for the elements of y .

Output Parameters

y	Contains the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpy` interface are the following:

<i>x</i>	Holds the array of size (<i>n</i>).
<i>y</i>	Holds the array of size (<i>n</i>).
<i>a</i>	The default value is 1.

?copy

Copies vector to another vector.

Syntax

FORTRAN 77:

```
call scopy(n, x, incx, y, incy)
call dcopy(n, x, incx, y, incy)
call ccopy(n, x, incx, y, incy)
call zcopy(n, x, incx, y, incy)
```

Fortran 95:

```
call copy(x, y)
```

Description

The `?copy` routines perform a vector-vector operation defined as

$$y = x,$$

where *x* and *y* are vectors.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>x</i>	REAL for <code>scopy</code> DOUBLE PRECISION for <code>dcopy</code>

	COMPLEX for ccopy
	DOUBLE COMPLEX for zcopy
	Array, DIMENSION at least $(1 + (n-1) * \text{abs}(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	REAL for scopy
	DOUBLE PRECISION for dcopy
	COMPLEX for ccopy
	DOUBLE COMPLEX for zcopy
	Array, DIMENSION at least $(1 + (n-1) * \text{abs}(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

Output Parameters

<i>y</i>	Contains a copy of the vector <i>x</i> if <i>n</i> is positive. Otherwise, parameters are unaltered.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `copy` interface are the following:

<i>x</i>	Holds the vector of length(<i>n</i>).
<i>y</i>	Holds the vector of length (<i>n</i>).

?dot

Computes a vector-vector dot product.

Syntax

FORTRAN 77:

```
res = sdot(n, x, incx, y, incy)
res = ddot(n, x, incx, y, incy)
```

Fortran 95:

```
res = dot(x, y)
```

Description

The `?dot` functions perform a vector-vector reduction operation defined as

$$\text{res} = \sum (x * y)$$

where x and y are vectors.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	REAL for <code>sdot</code> DOUBLE PRECISION for <code>ddot</code> Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$.
incx	INTEGER. Specifies the increment for the elements of x .
y	REAL for <code>sdot</code> DOUBLE PRECISION for <code>ddot</code> Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incy}))$.
incy	INTEGER. Specifies the increment for the elements of y .

Output Parameters

res	REAL for <code>sdot</code> DOUBLE PRECISION for <code>ddot</code> Contains the result of the dot product of x and y , if n is positive. Otherwise, res contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dot` interface are the following:

x	Holds the vector of length(n).
y	Holds the vector of length (n).

?sdot

Computes a vector-vector dot product with extended precision.

Syntax

FORTRAN 77:

```
res = sdsdot(n, sb, sx, incx, sy, incy)
res = dsdot(n, sx, incx, sy, incy)
```

Fortran 95:

```
res = sdot(sx, sy)
res = sdot(sx, sy, sb)
```

Description

The ?sdot functions compute the inner product of two vectors with extended precision. Both functions use extended precision accumulation of the intermediate results, but the function sdsdot outputs the final result in single precision, whereas the function dsdot outputs the double precision result. The function sdsdot also adds scalar value *sb* to the inner product.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in the input vectors <i>sx</i> and <i>sy</i> .
<i>sb</i>	REAL. Single precision scalar to be added to inner product (for the function sdsdot only).
<i>sx, sy</i>	REAL. Arrays, DIMENSION at least $(1+(n-1)*abs(incx))$ and $(1+(n-1)*abs(incy))$, respectively. Contain the input single precision vectors.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>sx</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>sy</i> .

Output Parameters

<i>res</i>	REAL for sdsdot DOUBLE PRECISION for dsdot

Contains the result of the dot product of sx and sy (with sb added for `sdsdot`), if n is positive. Otherwise, res contains sb for `sdsdot` and 0 for `dsdot`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sdot` interface are the following:

sx	Holds the vector of length(n).
sy	Holds the vector of length(n).

NOTE. Note that scalar parameter sb is declared as a required parameter in Fortran 95 interface for the function `sdot` to distinguish between function flavors that output final result in different precision.

?dotc

Computes a dot product of a conjugated vector with another vector.

Syntax

FORTRAN 77:

```
res = cdotc(n, x, incx, y, incy )
```

```
res = zdotc(n, x, incx, y, incy )
```

Fortran 95:

```
res = dotc(x, y)
```

Description

The `?dotc` functions perform a vector-vector operation defined as

$$res = \sum (\text{conjg}(x) * y)$$

where x and y are n -element vectors.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>x</i>	COMPLEX for <code>cdotc</code> DOUBLE COMPLEX for <code>zdotc</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	COMPLEX for <code>cdotc</code> DOUBLE COMPLEX for <code>zdotc</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

Output Parameters

<i>res</i>	COMPLEX for <code>cdotc</code> DOUBLE COMPLEX for <code>zdotc</code> Contains the result of the dot product of the conjugated <i>x</i> and unconjugated <i>y</i> , if <i>n</i> is positive. Otherwise, <i>res</i> contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotc` interface are the following:

<i>x</i>	Holds the vector of length(<i>n</i>).
<i>y</i>	Holds the vector of length (<i>n</i>).

?dotu

Computes a vector-vector dot product.

Syntax

FORTRAN 77:

```
res = cdotu(n, x, incx, y, incy )
```

```
res = zdotu(n, x, incx, y, incy )
```

Fortran 95:

```
res = dotu(x, y)
```

Description

The ?dotu functions perform a vector-vector reduction operation defined as

$$\text{res} = \sum (x^* y)$$

where x and y are n -element complex vectors.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	COMPLEX for cdotu DOUBLE COMPLEX for zdotu Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
incx	INTEGER. Specifies the increment for the elements of x .
y	COMPLEX for cdotu DOUBLE COMPLEX for zdotu Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$.
incy	INTEGER. Specifies the increment for the elements of y .

Output Parameters

res	COMPLEX for cdotu DOUBLE COMPLEX for zdotu Contains the result of the dot product of x and y , if n is positive. Otherwise, res contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotu` interface are the following:

x	Holds the vector of length(n).
y	Holds the vector of length (n).

?nrm2

Computes the Euclidean norm of a vector.

Syntax

FORTRAN 77:

```
res = snrm2(n, x, incx )
res = dnrm2(n, x, incx )
res = scnrm2(n, x, incx )
res = dznrm2(n, x, incx )
```

Fortran 95:

```
res = nrm2(x)
```

Description

The ?nrm2 functions perform a vector reduction operation defined as

$$res = ||x||,$$

where:

x is a vector

res is a value containing the Euclidean norm of the elements of x .

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
x	REAL for snrm2

DOUBLE PRECISION for dnorm2
 COMPLEX for scnorm2
 DOUBLE COMPLEX for dznorm2
Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
incx INTEGER. Specifies the increment for the elements of *x*.

Output Parameters

res REAL for snrm2
 DOUBLE PRECISION for dnorm2
 REAL for scnorm2
 DOUBLE PRECISION for dznorm2
 Contains the Euclidean norm of the vector *x*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `norm2` interface are the following:

x Holds the vector of length (n) .

?rot

Performs rotation of points in the plane.

Syntax

FORTRAN 77:

```
call srot( n, x, incx, y, incy, c, s )
call drot( n, x, incx, y, incy, c, s )
call csrot( n, x, incx, y, incy, c, s )
call zdrot( n, x, incx, y, incy, c, s )
```

Fortran 95:

```
call rot(x, y [,c] [,s])
```

Description

Given two complex vectors x and y , each vector element of these vectors is replaced as follows:

$$x(i) = c*x(i) + s*y(i)$$

$$y(i) = c*y(i) - s*x(i)$$

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	REAL for srot DOUBLE PRECISION for drot COMPLEX for csrot DOUBLE COMPLEX for zdrot Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .
y	REAL for srot DOUBLE PRECISION for drot COMPLEX for csrot DOUBLE COMPLEX for zdrot Array, DIMENSION at least $(1 + (n-1)*abs(incy))$.
$incy$	INTEGER. Specifies the increment for the elements of y .
c	REAL for srot DOUBLE PRECISION for drot REAL for csrot DOUBLE PRECISION for zdrot A scalar.
s	REAL for srot DOUBLE PRECISION for drot REAL for csrot DOUBLE PRECISION for zdrot A scalar.

Output Parameters

x	Each element is replaced by $c*x + s*y$.
y	Each element is replaced by $c*y - s*x$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rot` interface are the following:

<code>x</code>	Holds the vector of length(n).
<code>y</code>	Holds the vector of length (n).
<code>c</code>	The default value is 1.
<code>s</code>	The default value is 1.

?rotg

Computes the parameters for a Givens rotation.

Syntax

FORTRAN 77:

```
call srotg(a, b, c, s )
call drotg(a, b, c, s )
call crotg(a, b, c, s )
call zrotg(a, b, c, s )
```

Fortran 95:

```
call rotg(a, b, c, s)
```

Description

Given the cartesian coordinates (a, b) of a point p , these routines return the parameters a , b , c , and s associated with the Givens rotation that zeros the y -coordinate of the point.

See a more accurate LAPACK version [?lartg](#).

Input Parameters

<code>a</code>	REAL for srotg DOUBLE PRECISION for drotg COMPLEX for crotg

	DOUBLE COMPLEX for zrotg Provides the x -coordinate of the point p .
b	REAL for srotg DOUBLE PRECISION for drotg COMPLEX for crotg DOUBLE COMPLEX for zrotg Provides the y -coordinate of the point p .

Output Parameters

a	Contains the parameter r associated with the Givens rotation.
b	Contains the parameter z associated with the Givens rotation.
c	REAL for srotg DOUBLE PRECISION for drotg REAL for crotg DOUBLE PRECISION for zrotg Contains the parameter c associated with the Givens rotation.
s	REAL for srotg DOUBLE PRECISION for drotg COMPLEX for crotg DOUBLE COMPLEX for zrotg Contains the parameter s associated with the Givens rotation.

?rotm

Performs rotation of points in the modified plane.

Syntax

FORTRAN 77:

```
call srotm(n, x, incx, y, incy, param)
call drotm(n, x, incx, y, incy, param)
```

Fortran 95:

```
call rotm(x, y [,param])
```

Description

Given two complex vectors x and y , each vector element of these vectors is replaced as follows:

$$x(i) = H*x(i) + H*y(i)$$

$$y(i) = H*y(i) - H*x(i)$$

where:

H is a modified Givens transformation matrix whose values are stored in the $param(2)$ through $param(5)$ array. See discussion on the $param$ argument.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	REAL for srotm DOUBLE PRECISION for drotm Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
incx	INTEGER. Specifies the increment for the elements of x .
y	REAL for srotm DOUBLE PRECISION for drotm Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$.
incy	INTEGER. Specifies the increment for the elements of y .
$param$	REAL for srotm DOUBLE PRECISION for drotm Array, DIMENSION 5. The elements of the $param$ array are: $param(1)$ contains a switch, $flag$. $param(2-5)$ contain $h11$, $h21$, $h12$, and $h22$, respectively, the components of the array H . Depending on the values of $flag$, the components of H are set as follows:

$$flag = -1. : H = \begin{bmatrix} h11 & h12 \\ h21 & h22 \end{bmatrix}$$

$$flag = 0. : H = \begin{bmatrix} 1. & h12 \\ h21 & 1. \end{bmatrix}$$

$$flag = 1. : H = \begin{bmatrix} h11 & 1. \\ -1 & h22 \end{bmatrix}$$

$$flag = -2. : H = \begin{bmatrix} 1. & 0. \\ 0. & 1. \end{bmatrix}$$

In the last three cases, the matrix entries of 1., -1., and 0. are assumed based on the value of *flag* and are not required to be set in the *param* vector.

Output Parameters

<i>x</i>	Each element is replaced by $h11*x + h12*y$.
<i>y</i>	Each element is replaced by $h21*x + h22*y$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rotm` interface are the following:

<i>x</i>	Holds the vector of length(<i>n</i>).
<i>y</i>	Holds the vector of length (<i>n</i>).
<i>param</i>	The default value for <i>param</i> (1) is -2.

?rotmg

Computes parameters for a modified Givens rotation.

Syntax

FORTRAN 77:

```
call srotmg(d1, d2, x1, y1, param)
call drotmg(d1, d2, x1, y1, param)
```

Fortran 95:

```
call rotmg(x1, y1, param [, d1] [d2])
```

Description

Given cartesian coordinates $(x1, y1)$ of an input vector, these routines compute the components of a modified Givens transformation matrix H that zeros the y -component of the resulting vector:

$$\begin{bmatrix} x \\ 0 \end{bmatrix} = H \begin{bmatrix} \text{sqrt}(d_1)x_1 \\ \text{sqrt}(d_2)y_1 \end{bmatrix}$$

Input Parameters

$d1$	REAL for srotmg DOUBLE PRECISION for drotmg Provides the scaling factor for the x -coordinate of the input vector.
$d2$	REAL for srotmg DOUBLE PRECISION for drotmg Provides the scaling factor for the y -coordinate of the input vector.
$x1$	REAL for srotmg DOUBLE PRECISION for drotmg Provides the x -coordinate of the input vector.
$y1$	REAL for srotmg DOUBLE PRECISION for drotmg

Provides the y -coordinate of the input vector.

Output Parameters

<i>d1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the first diagonal element of the updated matrix.
<i>d2</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the second diagonal element of the updated matrix.
<i>x1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the x-coordinate of the rotated vector before scaling.
<i>param</i>	REAL for srotmg DOUBLE PRECISION for drotmg Array, DIMENSION 5. The elements of the <i>param</i> array are: <i>param</i>(1) contains a switch, <i>flag</i>. <i>param</i>(2-5) contain <i>h11</i>, <i>h21</i>, <i>h12</i>, and <i>h22</i>, respectively, the components of the array <i>H</i>. Depending on the values of <i>flag</i>, the components of <i>H</i> are set as follows:

$$flag = -1. : H = \begin{bmatrix} h11 & h12 \\ h21 & h22 \end{bmatrix}$$

$$flag = 0. : H = \begin{bmatrix} 1. & h12 \\ h21 & 1. \end{bmatrix}$$

$$flag = 1. : H = \begin{bmatrix} h11 & 1. \\ -1 & h22 \end{bmatrix}$$

$$flag = -2. : H = \begin{bmatrix} 1. & 0. \\ 0. & 1. \end{bmatrix}$$

In the last three cases, the matrix entries of 1., -1., and 0. are assumed based on the value of *flag* and are not required to be set in the *param* vector.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rotmg` interface are the following:

<i>d1</i>	The default value is 1.
<i>d2</i>	The default value is 1.

?scal

Computes a vector by a scalar product.

Syntax

FORTRAN 77:

```
call sscal(n, a, x, incx )
call dscal(n, a, x, incx )
call cscal(n, a, x, incx )
call zscal(n, a, x, incx )
call csscal(n, a, x, incx )
call zdscal(n, a, x, incx )
```

Fortran 95:

```
call scal(x, a)
```

Description

The `?scal` routines perform a vector-vector operation defined as

$$x = a * x$$

where:

a is a scalar, x is an n -element vector.

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
a	REAL for <code>sscal</code> and <code>csscal</code> DOUBLE PRECISION for <code>dscal</code> and <code>zdsal</code> COMPLEX for <code>cscal</code> DOUBLE COMPLEX for <code>zscal</code> Specifies the scalar a .
x	REAL for <code>sscal</code> DOUBLE PRECISION for <code>dscal</code> COMPLEX for <code>cscal</code> and <code>csscal</code> DOUBLE COMPLEX for <code>zscal</code> and <code>zdsal</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
incx	INTEGER. Specifies the increment for the elements of x .

Output Parameters

x	Updated vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `scal` interface are the following:

x	Holds the vector of length(n).

?swap

Swaps a vector with another vector.

Syntax

FORTRAN 77:

```
call sswap(n, x, incx, y, incy)
call dswap(n, x, incx, y, incy)
call cswap(n, x, incx, y, incy)
call zswap(n, x, incx, y, incy)
```

Fortran 95:

```
call swap(x, y)
```

Description

Given two vectors x and y , the ?swap routines return vectors y and x swapped, each replacing the other.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	REAL for sswap DOUBLE PRECISION for dswap COMPLEX for cswap DOUBLE COMPLEX for zswap Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .
y	REAL for sswap DOUBLE PRECISION for dswap COMPLEX for cswap DOUBLE COMPLEX for zswap Array, DIMENSION at least $(1 + (n-1)*abs(incy))$.
$incy$	INTEGER. Specifies the increment for the elements of y .

Output Parameters

x	Contains the resultant vector x , that is, the input vector y .
y	Contains the resultant vector y , that is, the input vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `swap` interface are the following:

x	Holds the vector of length(n).
y	Holds the vector of length(n).

i?amax

Finds the index of the element with maximum absolute value.

Syntax

FORTRAN 77:

```
index = isamax(n, x, incx )
index = idamax(n, x, incx )
index = icamax(n, x, incx )
index = izamax(n, x, incx )
```

Fortran 95:

```
index = iamax(x)
```

Description

Given a vector x , the `i?amax` functions return the position of the vector element $x(i)$ that has the largest absolute value for real flavors, or the largest sum $|\text{Re}(x(i))| + |\text{Im}(x(i))|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same largest absolute value, the index of the first one encountered is returned.

Input Parameters

<i>n</i>	INTEGER. Specifies the order of the vector <i>x</i> .
<i>x</i>	REAL for <code>isamax</code> DOUBLE PRECISION for <code>idamax</code> COMPLEX for <code>icamax</code> DOUBLE COMPLEX for <code>izamax</code> Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .

Output Parameters

<i>index</i>	INTEGER. Contains the position of vector element <i>x</i> that has the largest absolute value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `iamax` interface are the following:

<i>x</i>	Holds the vector of length (<i>n</i>).

i?amin

Finds the index of the element with the smallest absolute value.

Syntax

FORTRAN 77:

```
index = isamin(n, x, incx)
index = idamin(n, x, incx)
index = icamin(n, x, incx)
index = izamin(n, x, incx)
```

Fortran 95:

```
index = iamin(x)
```

Description

Given a vector x , the `i?amin` functions return the position of the vector element $x(i)$ that has the smallest absolute value for real flavors, or the smallest sum $|\text{Re}(x(i))| + |\text{Im}(x(i))|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same smallest absolute value, the index of the first one encountered is returned.

Input Parameters

n	INTEGER. On entry, n specifies the order of the vector x .
x	REAL for <code>isamin</code> DOUBLE PRECISION for <code>idamin</code> COMPLEX for <code>icamin</code> DOUBLE COMPLEX for <code>izamin</code> Array, DIMENSION at least $(1+(n-1)*\text{abs}(\text{incx}))$.
incx	INTEGER. Specifies the increment for the elements of x .

Output Parameters

index	INTEGER. Contains the position of vector element x that has the smallest absolute value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `iamin` interface are the following:

x	Holds the vector of length (n) .

dcabs1

Computes absolute value of double complex number.

Syntax

FORTRAN 77:

```
res = dcabs1(z)
```

Fortran 95:

```
res = dcabs1(z)
```

Description

The `dcabs1` is an auxiliary routine for a few BLAS Level 1 routines. This function performs an operation defined as

$res = |\operatorname{Re}(z)| + |\operatorname{Im}(z)|$,

where z is a scalar and res is a value containing the absolute value of a double complex number z .

Input Parameters

z DOUBLE COMPLEX scalar.

Output Parameters

res DOUBLE PRECISION.
Contains the absolute value of a double complex number z .

BLAS Level 2 Routines

This section describes BLAS Level 2 routines, which perform matrix-vector operations. [Table 2-2](#) lists the BLAS Level 2 routine groups and the data types associated with them.

Table 2-2 BLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
?gbmv	s, d, c, z	Matrix-vector product using a general band matrix
?gemv	s, d, c, z	Matrix-vector product using a general matrix

Routine Groups	Data Types	Description
?ger	s, d	Rank-1 update of a general matrix
?gerc	c, z	Rank-1 update of a conjugated general matrix
?geru	c, z	Rank-1 update of a general matrix, unconjugated
?hbmV	c, z	Matrix-vector product using a Hermitian band matrix
?hemv	c, z	Matrix-vector product using a Hermitian matrix
?her	c, z	Rank-1 update of a Hermitian matrix
?her2	c, z	Rank-2 update of a Hermitian matrix
?hpmv	c, z	Matrix-vector product using a Hermitian packed matrix
?hpr	c, z	Rank-1 update of a Hermitian packed matrix
?hpr2	c, z	Rank-2 update of a Hermitian packed matrix
?sbmv	s, d	Matrix-vector product using symmetric band matrix
?spmv	s, d	Matrix-vector product using a symmetric packed matrix
?spr	s, d	Rank-1 update of a symmetric packed matrix
?spr2	s, d	Rank-2 update of a symmetric packed matrix
?symv	s, d	Matrix-vector product using a symmetric matrix
?syr	s, d	Rank-1 update of a symmetric matrix
?syr2	s, d	Rank-2 update of a symmetric matrix
?tbmv	s, d, c, z	Matrix-vector product using a triangular band matrix
?tbsv	s, d, c, z	Solution of a linear system of equations with a triangular band matrix

Routine Groups	Data Types	Description
?tpmv	s, d, c, z	Matrix-vector product using a triangular packed matrix
?tpsv	s, d, c, z	Solution of a linear system of equations with a triangular packed matrix
?trmv	s, d, c, z	Matrix-vector product using a triangular matrix
?trsv	s, d, c, z	Solution of a linear system of equations with a triangular matrix

?gbmv

Computes a matrix-vector product using a general band matrix

Syntax

FORTRAN 77:

```
call sgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy )
call dgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy )
call cgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy )
call zgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy )
```

Fortran 95:

```
call gbmv(a, x, y [,kl] [,m] [,alpha] [,beta] [,trans])
```

Description

The ?gbmv routines perform a matrix-vector operation defined as

```
y := alpha*A*x + beta*y
```

or

```
y := alpha*A'*x + beta*y,
```

or

```
y := alpha *conjg(A')*x + beta*y,
```

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*n* band matrix, with *kl* sub-diagonals and *ku* super-diagonals.

Input Parameters

<i>trans</i>	CHARACTER*1. Specifies the operation: If <i>trans</i>= 'N' or 'n', then $y := \alpha A * x + \beta y$ If <i>trans</i>= 'T' or 't', then $y := \alpha A' * x + \beta y$ If <i>trans</i>= 'C' or 'c', then $y := \alpha \text{conjg}(A') * x + \beta y$
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i>. The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>kl</i>	INTEGER. Specifies the number of sub-diagonals of the matrix <i>A</i>. The value of <i>kl</i> must satisfy $0 \leq kl$.
<i>ku</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i>. The value of <i>ku</i> must satisfy $0 \leq ku$.
<i>alpha</i>	REAL for sgbmv DOUBLE PRECISION for dgbmv COMPLEX for cgbmv DOUBLE COMPLEX for zgbmv Specifies the scalar <i>alpha</i>.
<i>a</i>	REAL for sgbmv DOUBLE PRECISION for dgbmv COMPLEX for cgbmv DOUBLE COMPLEX for zgbmv Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry, the leading $(kl + ku + 1)$ by <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients. This matrix must be supplied column-by-column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row <i>ku</i>, the first

sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array a that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced.

The following program segment transfers a band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    k = ku + 1 - j
    do 10, i = max(1, j-ku), min(m, j+kl)
        a(k+i, j) = matrix(i,j)
    10 continue
20 continue

```

lda INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $(kl + ku + 1)$.

x REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv
DOUBLE COMPLEX for zgbmv
Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$ when $\text{trans} = 'N'$ or $'n'$, and at least $(1 + (m - 1) * \text{abs}(\text{incx}))$ otherwise. Before entry, the array x must contain the vector x .

incx INTEGER. Specifies the increment for the elements of x . incx must not be zero.

beta REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv
DOUBLE COMPLEX for zgbmv
Specifies the scalar beta. When beta is equal to zero, then y need not be set on input.

y REAL for sgbmv
DOUBLE PRECISION for dgbmv
COMPLEX for cgbmv

DOUBLE COMPLEX for `zgbmv`

Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incy}))$ when `trans = 'N'` or `'n'` and at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry, the incremented array `y` must contain the vector `y`.

`incy`

INTEGER. Specifies the increment for the elements of `y`. The value of `incy` must not be zero.

Output Parameters

`y`

Updated vector `y`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbmv` interface are the following:

`a`

Holds the array `a` of size $(kl+ku+1, n)$. Contains a banded matrix $m*n$ with `kl` lower diagonal and `ku` upper diagonal.

`x`

Holds the vector of length (rx) , where $rx = n$ if `trans = 'N'`, $rx = m$ otherwise.

`y`

Holds the vector of length (ry) , where $ry = m$ if `trans = 'N'`, $ry = n$ otherwise.

`trans`

Must be `'N'`, `'C'`, or `'T'`.
The default value is `'N'`.

`kl`

If omitted, assumed $kl = ku$, that is, the number of lower diagonals equals the number of the upper diagonals.

`ku`

Restored as $ku = lda - kl - 1$, where `lda` is the first dimension of matrix `A`.

`m`

If omitted, assumed $m = n$, that is, a square matrix.

`alpha`

The default value is 1.

`beta`

The default value is 1.

?gemv

Computes a matrix-vector product using a general matrix

Syntax

FORTRAN 77:

```
call sgemv( trans, m, n, alpha, a, lda, x, incx, beta, y, incy )
call dgemv( trans, m, n, alpha, a, lda, x, incx, beta, y, incy )
call cgemv( trans, m, n, alpha, a, lda, x, incx, beta, y, incy )
call zgemv( trans, m, n, alpha, a, lda, x, incx, beta, y, incy )
```

Fortran 95:

```
call gemv( a, x, y [,alpha][,beta] [,trans] )
```

Description

The ?gemv routines perform a matrix-vector operation defined as

$y := \alpha A x + \beta y,$

or

$y := \alpha A' x + \beta y,$

or

$y := \alpha \text{conjg}(A') x + \beta y,$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- n matrix.

Input Parameters

trans CHARACTER*1. Specifies the operation:
 if *trans*= 'N' or 'n', then $y := \alpha A x + \beta y$;
 if *trans*= 'T' or 't', then $y := \alpha A' x + \beta y$;

	if <i>trans</i> = 'C' or 'c', then $y := \alpha * \text{conjg}(A') * x + \beta * y$.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.
<i>x</i>	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv Array, DIMENSION at least $(1 + (n-1) * \text{abs}(\text{incx}))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(\text{incx}))$ otherwise. Before entry, the incremented array <i>x</i> must contain the vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv

	Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incy}))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{incy}))$ otherwise. Before entry with non-zero <i>beta</i> , the incremented array <i>y</i> must contain the vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gemv` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m,n) .
<i>x</i>	Holds the vector of length (rx) where $rx = n$ if <i>trans</i> = 'N', $rx = m$ otherwise.
<i>y</i>	Holds the vector of length (ry) where $ry = m$ if <i>trans</i> = 'N', $ry = n$ otherwise.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?ger

Performs a rank-1 update of a general matrix.

Syntax

FORTRAN 77:

```
call sger(m, n, alpha, x, incx, y, incy, a, lda )
call dger(m, n, alpha, x, incx, y, incy, a, lda )
```

Fortran 95:

```
call ger(a, x, y [,alpha])
```

Description

The ?ger routines perform a matrix-vector operation defined as

$$A := \alpha x y^T + A,$$

where:

α is a scalar,

x is an m -element vector,

y is an n -element vector,

A is an m -by- n matrix.

Input Parameters

m	INTEGER. Specifies the number of rows of the matrix A . The value of m must be at least zero.
n	INTEGER. Specifies the number of columns of the matrix A . The value of n must be at least zero.
α	REAL for sger DOUBLE PRECISION for dger Specifies the scalar α .
x	REAL for sger DOUBLE PRECISION for dger

	Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the m -element vector x .
$incx$	INTEGER. Specifies the increment for the elements of x . The value of $incx$ must not be zero.
y	REAL for sger DOUBLE PRECISION for dger Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .
$incy$	INTEGER. Specifies the increment for the elements of y . The value of $incy$ must not be zero.
a	REAL for sger DOUBLE PRECISION for dger Array, DIMENSION (lda, n) . Before entry, the leading m -by- n part of the array a must contain the matrix of coefficients.
lda	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, m)$.

Output Parameters

a	Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ger` interface are the following:

a	Holds the matrix A of size (m, n) .
x	Holds the vector of length (m) .
y	Holds the vector of length (n) .
$alpha$	The default value is 1.

?gerc

Performs a rank-1 update (conjugated) of a general matrix.

Syntax

FORTRAN 77:

```
call cgerc(m, n, alpha, x, incx, y, incy, a, lda )
call zgerc(m, n, alpha, x, incx, y, incy, a, lda )
```

Fortran 95:

```
call gerc(a, x, y [,alpha])
```

Description

The ?gerc routines perform a matrix-vector operation defined as

$$A := \alpha x \text{conjg}(y') + A,$$

where:

alpha is a scalar,

x is an *m*-element vector,

y is an *n*-element vector,

A is an *m*-by-*n* matrix.

Input Parameters

<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cgerc DOUBLE COMPLEX for zgerc Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cgerc DOUBLE COMPLEX for zgerc

	Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the m -element vector x .
$incx$	INTEGER. Specifies the increment for the elements of x . The value of $incx$ must not be zero.
y	COMPLEX for <code>cgerc</code> DOUBLE COMPLEX for <code>zgerc</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .
$incy$	INTEGER. Specifies the increment for the elements of y . The value of $incy$ must not be zero.
a	COMPLEX for <code>cgerc</code> DOUBLE COMPLEX for <code>zgerc</code> Array, DIMENSION (lda, n) . Before entry, the leading m -by- n part of the array a must contain the matrix of coefficients.
lda	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, m)$.

Output Parameters

a	Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gerc` interface are the following:

a	Holds the matrix A of size (m, n) .
x	Holds the vector of length (m) .
y	Holds the vector of length (n) .
$alpha$	The default value is 1.

?geru

Performs a rank-1 update (unconjugated) of a general matrix.

Syntax

FORTRAN 77:

```
call cgeru(m, n, alpha, x, incx, y, incy, a, lda )
call zgeru(m, n, alpha, x, incx, y, incy, a, lda )
```

Fortran 95:

```
call geru(a, x, y [,alpha])
```

Description

The ?geru routines perform a matrix-vector operation defined as

$$A := \alpha x y^T + A,$$

where:

alpha is a scalar,

x is an *m*-element vector,

y is an *n*-element vector,

A is an *m*-by-*n* matrix.

Input Parameters

<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cgeru DOUBLE COMPLEX for zgeru

	Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the m -element vector x .
$incx$	INTEGER. Specifies the increment for the elements of x . The value of $incx$ must not be zero.
y	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .
$incy$	INTEGER. Specifies the increment for the elements of y . The value of $incy$ must not be zero.
a	COMPLEX for cgeru DOUBLE COMPLEX for zgeru Array, DIMENSION (lda, n) . Before entry, the leading m -by- n part of the array a must contain the matrix of coefficients.
lda	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, m)$.

Output Parameters

a	Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geru` interface are the following:

a	Holds the matrix A of size (m, n) .
x	Holds the vector of length (m) .
y	Holds the vector of length (n) .
$alpha$	The default value is 1.

?hbmV

Computes a matrix-vector product using a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbmV(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy )
call zhbmV(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy )
```

Fortran 95:

```
call hbmV(a, x, y [,uplo][,alpha] [,beta])
```

Description

The ?hbmV routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian band matrix, with *k* super-diagonals.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian band matrix <i>A</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>k</i> must satisfy $0 \leq k$.
<i>alpha</i>	COMPLEX for chbmV

a

DOUBLE COMPLEX for zhbmv

Specifies the scalar *alpha*.

COMPLEX for chbmvm

DOUBLE COMPLEX for zhbmv

Array, DIMENSION (*lda*, *n*).

Before entry with *uplo* = 'U' or 'u', the leading (*k* + 1) by *n* part of the array *a* must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied column-by-column, with the leading diagonal of the matrix in row (*k* + 1) of the array, the first super-diagonal starting at position 2 in row *k*, and so on. The top left *k* by *k* triangle of the array *a* is not referenced. The following program segment transfers the upper triangular part of a Hermitian band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = k + 1 - j
    do 10, i = max(1, j - k), j
        a(m + i, j) = matrix(i, j)
    10 continue
20 continue

```

Before entry with *uplo* = 'L' or 'l', the leading (*k* + 1) by *n* part of the array *a* must contain the lower triangular band part of the Hermitian matrix, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right *k* by *k* triangle of the array *a* is not referenced.

The following program segment transfers the lower triangular part of a Hermitian band matrix from conventional full matrix storage to band storage:

```
do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min( n, j + k )
        a( m + i, j ) = matrix( i, j )
    10 continue
20 continue
```

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $(k + 1)$.
<i>x</i>	COMPLEX for chbmv DOUBLE COMPLEX for zhbmv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for chbmv DOUBLE COMPLEX for zhbmv Specifies the scalar <i>beta</i> .
<i>y</i>	COMPLEX for chbmv DOUBLE COMPLEX for zhbmv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbmV` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(k+1, n)$.
<i>x</i>	Holds the vector of length (n) .
<i>y</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?hemv

Computes a matrix-vector product using a Hermitian matrix.

Syntax

FORTRAN 77:

```
call chemv(uplo, n, alpha, a, lda, x, incx, beta, y, incy )
call zhemv(uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

Fortran 95:

```
call hemv(a, x, y [,uplo][,alpha] [,beta])
```

Description

The `?hemv` routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv Specifies the scalar <i>alpha</i>.
<i>a</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for chemv

	DOUBLE COMPLEX for <code>zhemv</code> Specifies the scalar <code>beta</code> . When <code>beta</code> is supplied as zero then <code>y</code> need not be set on input.
<code>y</code>	COMPLEX for <code>chemv</code> DOUBLE COMPLEX for <code>zhemv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <code>y</code> must contain the n -element vector <code>y</code> .
<code>incy</code>	INTEGER. Specifies the increment for the elements of <code>y</code> . The value of <code>incy</code> must not be zero.

Output Parameters

<code>y</code>	Overwritten by the updated vector <code>y</code> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hemv` interface are the following:

<code>a</code>	Holds the matrix <code>A</code> of size (n, n) .
<code>x</code>	Holds the vector of length (n) .
<code>y</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.
<code>beta</code>	The default value is 1.

?her

Performs a rank-1 update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher(uplo, n, alpha, x, incx, a, lda )
call zher(uplo, n, alpha, x, incx, a, lda )
```

Fortran 95:

```
call her(a, x [,uplo] [, alpha])
```

Description

The ?her routines perform a matrix-vector operation defined as

$$A := \alpha x \text{conjg}(x') + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for cher DOUBLE PRECISION for zher Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for cher DOUBLE COMPLEX for zher

	Array, dimension at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n -element vector x .
<i>incx</i>	INTEGER. Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero.
<i>a</i>	COMPLEX for cher DOUBLE COMPLEX for zher Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of a is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array a is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array a is overwritten by the lower triangular part of the updated matrix. The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n,n) .
<i>x</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?her2

Performs a rank-2 update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher2(uplo, n, alpha, x, incx, y, incy, a, lda )
call zher2(uplo, n, alpha, x, incx, y, incy, a, lda )
```

Fortran 95:

```
call her2(a, x, y [,uplo][,alpha])
```

Description

The ?her2 routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.

<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

a With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.
 The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her2` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n,n) .
<i>x</i>	Holds the vector of length (n) .
<i>y</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?hpmv

Computes a matrix-vector product using a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpmv(uplo, n, alpha, ap, x, incx, beta, y, incy )
call zhpmv(uplo, n, alpha, ap, x, incx, beta, y, incy )
```

Fortran 95:

```
call hpmv(a, x, y [,uplo][,alpha] [,beta])
```

Description

The ?hpmv routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n Hermitian matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array ap. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix A is supplied in the packed array ap. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix A is supplied in the packed array ap.
<i>n</i>	INTEGER. Specifies the order of the matrix A. The value of n must be at least zero.
<i>alpha</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Specifies the scalar α.
<i>ap</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Array, DIMENSION at least $((n*(n+1))/2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array ap must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1, 1)$, $ap(2)$ and $ap(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array ap must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1, 1)$, $ap(2)$ and $ap(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.

	The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>x</i>	COMPLEX for <code>chpmv</code> DOUBLE PRECISION COMPLEX for <code>zhpmv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for <code>chpmv</code> DOUBLE COMPLEX for <code>zhpmv</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero then <i>y</i> need not be set on input.
<i>y</i>	COMPLEX for <code>chpmv</code> DOUBLE COMPLEX for <code>zhpmv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpmv` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(n * (n + 1) / 2)$.
<i>x</i>	Holds the vector of length (<i>n</i>).
<i>y</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

beta

The default value is 1.

?hpr

Performs a rank-1 update of a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpr(uplo, n, alpha, x, incx, ap)
```

```
call zhpr(uplo, n, alpha, x, incx, ap)
```

Fortran 95:

```
call hpr(a, x [,uplo] [, alpha])
```

Description

The ?hpr routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(x') + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for chpr

	DOUBLE PRECISION for zhpr Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for chpr DOUBLE COMPLEX for zhpr Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero.
<i>ap</i>	COMPLEX for chpr DOUBLE COMPLEX for zhpr Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (1, 2) and <i>a</i> (2, 2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (2, 1) and <i>a</i> (3, 1) respectively, and so on. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

<i>ap</i>	With <i>uplo</i> = 'U' or 'u', overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', overwritten by the lower triangular part of the updated matrix. The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpr` interface are the following:

<code>a</code>	Holds the array <code>a</code> of size $(n*(n+1)/2)$.
<code>x</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.

?hpr2

Performs a rank-2 update of a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpr2(uplo, n, alpha, x, incx, y, incy, ap )
call zhpr2(uplo, n, alpha, x, incx, y, incy, ap )
```

Fortran 95:

```
call hpr2(a, x, y [,uplo][,alpha])
```

Description

The `?hpr2` routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A,$$

where:

`alpha` is a scalar,

`x` and `y` are n -element vectors,

`A` is an n -by- n Hermitian matrix, supplied in packed form.

Input Parameters

`uplo` CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix `A` is supplied in the packed array `ap`.
If `uplo = 'U'` or `'u'`, then the upper triangular part of the matrix `A` is supplied in the packed array `ap`.

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for <i>chpr2</i> DOUBLE COMPLEX for <i>zhpr2</i> Specifies the scalar <i>alpha</i>.
<i>x</i>	COMPLEX for <i>chpr2</i> DOUBLE COMPLEX for <i>zhpr2</i> Array, dimension at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <i>chpr2</i> DOUBLE COMPLEX for <i>zhpr2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i>-element vector <i>y</i>.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i>. The value of <i>incy</i> must not be zero.
<i>ap</i>	COMPLEX for <i>chpr2</i> DOUBLE COMPLEX for <i>zhpr2</i> Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(1,2) and <i>a</i>(2,2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(2,1) and <i>a</i>(3,1) respectively, and so on. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.
 The imaginary parts of the diagonal elements need are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpr2` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(n * (n+1) / 2)$.
<i>x</i>	Holds the vector of length (n) .
<i>y</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?sbmv

Computes a matrix-vector product using a symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
call dsbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call sbmv(a, x, y [,uplo][,alpha] [,beta])
```

Description

The ?sbmv routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n symmetric band matrix, with k super-diagonals.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix A is used: if <i>uplo</i> = 'U' or 'u' - upper triangular part; if <i>uplo</i> = 'L' or 'l' - low triangular part.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>k</i>	INTEGER. Specifies the number of super-diagonals of the matrix A . The value of k must satisfy $0 \leq k$.
<i>alpha</i>	REAL for ssbmv DOUBLE PRECISION for dsbmv Specifies the scalar α .
<i>a</i>	REAL for ssbmv DOUBLE PRECISION for dsbmv Array, DIMENSION (<i>lda</i> , n). Before entry with <i>uplo</i> = 'U' or 'u', the leading $(k + 1)$ by n part of the array a must contain the upper triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array a is not referenced.

The following program segment transfers the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = k + 1 - j
    do 10, i = max( 1, j - k ), j
        a( m + i, j ) = matrix( i, j )
    10 continue
20 continue

```

Before entry with `uplo = 'L' or 'l'`, the leading $(k + 1)$ by n part of the array `a` must contain the lower triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array `a` is not referenced.

The following program segment transfers the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min( n, j + k )
        a( m + i, j ) = matrix( i, j )
    10 continue
20 continue

```

`lda`

INTEGER. Specifies the first dimension of `a` as declared in the calling (sub)program. The value of `lda` must be at least $(k + 1)$.

`x`

REAL for `ssbmv`

DOUBLE PRECISION for `dsbmv`

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.

Before entry, the incremented array `x` must contain the vector `x`.

<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for <i>ssbm</i> v DOUBLE PRECISION for <i>dsbm</i> v Specifies the scalar <i>beta</i> .
<i>y</i>	REAL for <i>ssbm</i> v DOUBLE PRECISION for <i>dsbm</i> v Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sbmv* interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(k+1, n)$.
<i>x</i>	Holds the vector of length (n) .
<i>y</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?spmv

Computes a matrix-vector product using a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspmv(uplo, n, alpha, ap, x, incx, beta, y, incy )
call dspmv(uplo, n, alpha, ap, x, incx, beta, y, incy )
```

Fortran 95:

```
call spmv(a, x, y [,uplo][,alpha] [,beta])
```

Description

The ?spmv routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n symmetric matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array ap. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix A is supplied in the packed array ap. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix A is supplied in the packed array ap.
<i>n</i>	INTEGER. Specifies the order of the matrix a. The value of n must be at least zero.
<i>alpha</i>	REAL for sspmv DOUBLE PRECISION for dspmv Specifies the scalar α.

<i>ap</i>	REAL for <code>sspmv</code> DOUBLE PRECISION for <code>dspmv</code> Array, DIMENSION at least $(n*(n + 1))/2$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(1,2) and <i>a</i>(2, 2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(2,1) and <i>a</i>(3,1) respectively, and so on.
<i>x</i>	REAL for <code>sspmv</code> DOUBLE PRECISION for <code>dspmv</code> Array, DIMENSION at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for <code>sspmv</code> DOUBLE PRECISION for <code>dspmv</code> Specifies the scalar <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for <code>sspmv</code> DOUBLE PRECISION for <code>dspmv</code> Array, DIMENSION at least $(1 + (n - 1)*abs(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i>-element vector <i>y</i>.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i>. The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spmv` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(n*(n+1)/2)$.
<i>x</i>	Holds the vector of length (<i>n</i>).
<i>y</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?spr

Performs a rank-1 update of a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspr(uplo, n, alpha, x, incx, ap )
call dspr(uplo, n, alpha, x, incx, ap )
```

Fortran 95:

```
call spr(a, x [,uplo] [, alpha])
```

Description

The `?spr` routines perform a matrix-vector operation defined as

$$a := \alpha * x * x' + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sspr DOUBLE PRECISION for dspr Specifies the scalar <i>alpha</i>.
<i>x</i>	REAL for sspr DOUBLE PRECISION for dspr Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>ap</i>	REAL for sspr DOUBLE PRECISION for dspr Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(1,2) and <i>a</i>(2,2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(2,1) and <i>a</i>(3,1) respectively, and so on.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spr* interface are the following:

a Holds the array *a* of size $(n*(n+1)/2)$.
x Holds the vector of length (n) .
uplo Must be 'U' or 'L'. The default value is 'U'.
alpha The default value is 1.

?spr2

Performs a rank-2 update of a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspr2(uplo, n, alpha, x, incx, y, incy, ap )
call dspr2(uplo, n, alpha, x, incx, y, incy, ap )
```

Fortran 95:

```
call spr2(a, x, y [,uplo][,alpha])
```

Description

The ?spr2 routines perform a matrix-vector operation defined as

$$A := \alpha x y' + \alpha y x' + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i>.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Specifies the scalar <i>alpha</i>.
<i>x</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i>-element vector <i>y</i>.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i>. The value of <i>incy</i> must not be zero.
<i>ap</i>	REAL for sspr2 DOUBLE PRECISION for dspr2

Array, `DIMENSION` at least $((n * (n + 1)) / 2)$. Before entry with `uplo = 'U' or 'u'`, the array `ap` must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that `ap(1)` contains $a(1,1)$, `ap(2)` and `ap(3)` contain $a(1,2)$ and $a(2,2)$ respectively, and so on.

Before entry with `uplo = 'L' or 'l'`, the array `ap` must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that `ap(1)` contains $a(1,1)$, `ap(2)` and `ap(3)` contain $a(2,1)$ and $a(3,1)$ respectively, and so on.

Output Parameters

`ap`

With `uplo = 'U' or 'u'`, overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L' or 'l'`, overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spr2` interface are the following:

<code>a</code>	Holds the array <code>a</code> of size $(n * (n + 1)) / 2$.
<code>x</code>	Holds the vector of length (n) .
<code>y</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.

?symv

Computes a matrix-vector product for a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssymv(uplo, n, alpha, a, lda, x, incx, beta, y, incy )
call dsymv(uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

Fortran 95:

```
call symv(a, x, y [,uplo][,alpha] [,beta])
```

Description

The ?symv routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for ssymv DOUBLE PRECISION for dsymv Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for ssymv

	DOUBLE PRECISION for dsymv Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	REAL for ssymv DOUBLE PRECISION for dsymv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for ssymv DOUBLE PRECISION for dsymv Specifies the scalar <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for ssymv DOUBLE PRECISION for dsymv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i>-element vector <i>y</i>.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i>. The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `symv` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n,n) .
<i>x</i>	Holds the vector of length (n) .
<i>y</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?syr

Performs a rank-1 update of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr(uplo, n, alpha, x, incx, a, lda )
call dsyr(uplo, n, alpha, x, incx, a, lda )
```

Fortran 95:

```
call syr(a, x [,uplo] [, alpha])
```

Description

The `?syr` routines perform a matrix-vector operation defined as

$$A := \alpha * x * x' + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for ssyr DOUBLE PRECISION for dsyr Specifies the scalar <i>alpha</i>.
<i>x</i>	REAL for ssyr DOUBLE PRECISION for dsyr Array, DIMENSION at least $(1 + (n-1)*abs(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.
<i>a</i>	REAL for ssyr DOUBLE PRECISION for dsyr Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

a With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n,n) .
<i>x</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?syr2

Performs a rank-2 update of symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr2(uplo, n, alpha, x, incx, y, incy, a, lda )
call dsyr2(uplo, n, alpha, x, incx, y, incy, a, lda )
```

Fortran 95:

```
call syr2(a, x, y [,uplo][,alpha])
```

Description

The `?syr2` routines perform a matrix-vector operation defined as

$$A := \alpha x x^T + \alpha y y^T + A,$$

where:

α is a scalar,

x and y are n -element vectors,

A is an n -by- n symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array a is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array a is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array a is used.
<i>n</i>	INTEGER. Specifies the order of the matrix A. The value of n must be at least zero.
<i>alpha</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Specifies the scalar α.
<i>x</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n-element vector x.
<i>incx</i>	INTEGER. Specifies the increment for the elements of x. The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array y must contain the n-element vector y.
<i>incy</i>	INTEGER. Specifies the increment for the elements of y. The value of <i>incy</i> must not be zero.
<i>a</i>	REAL for ssyr2 DOUBLE PRECISION for dsyr2 Array, DIMENSION (lda, n).

Before entry with `uplo = 'U' or 'u'`, the leading n -by- n upper triangular part of the array `a` must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of `a` is not referenced.

Before entry with `uplo = 'L' or 'l'`, the leading n -by- n lower triangular part of the array `a` must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of `a` is not referenced.

`lda`

INTEGER. Specifies the first dimension of `a` as declared in the calling (sub)program. The value of `lda` must be at least $\max(1, n)$.

Output Parameters

`a`

With `uplo = 'U' or 'u'`, the upper triangular part of the array `a` is overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L' or 'l'`, the lower triangular part of the array `a` is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sy2` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>x</code>	Holds the vector x of length (n) .
<code>y</code>	Holds the vector y of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.

?tbmv

Computes a matrix-vector product using a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbmv(uplo, trans, diag, n, k, a, lda, x, incx )
call dtbmv(uplo, trans, diag, n, k, a, lda, x, incx )
call ctbmv(uplo, trans, diag, n, k, a, lda, x, incx )
call ztbmv(uplo, trans, diag, n, k, a, lda, x, incx )
```

Fortran 95:

```
call tbmv(a, x [,uplo] [, trans] [,diag])
```

Description

The ?tbmv routines perform one of the matrix-vector operations defined as

$x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is an upper or lower triangular matrix: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $x := A*x$; if <i>trans</i> = 'T' or 't', then $x := A'*x$; if <i>trans</i> = 'C' or 'c', then $x := \text{conjg}(A')*x$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular:

if *diag* = 'U' or 'u' then the matrix is unit triangular;
 if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n INTEGER. Specifies the order of the matrix *A*. The value of *n* must be at least zero.

k INTEGER. On entry with *uplo* = 'U' or 'u', *k* specifies the number of super-diagonals of the matrix *A*. On entry with *uplo* = 'L' or 'l', *k* specifies the number of sub-diagonals of the matrix *a*.
 The value of *k* must satisfy $0 \leq k$.

a REAL for *stbmv*
 DOUBLE PRECISION for *dtbmv*
 COMPLEX for *ctbmv*
 DOUBLE COMPLEX for *ztbmv*
 Array, DIMENSION (*lda*, *n*).
 Before entry with *uplo* = 'U' or 'u', the leading (*k* + 1) by *n* part of the array *a* must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row (*k* + 1) of the array, the first super-diagonal starting at position 2 in row *k*, and so on. The top left *k* by *k* triangle of the array *a* is not referenced. The following program segment transfers an upper triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = k + 1 - j
do 10, i = max(1, j - k), j
    a(m + i, j) = matrix(i, j)
10 continue
20 continue
  
```

Before entry with *uplo* = 'L' or 'l', the leading (*k* + 1) by *n* part of the array *a* must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right *k* by *k*

triangle of the array *a* is not referenced. The following program segment transfers a lower triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
  m = 1 - j
  do 10, i = j, min(n, j + k)
    a(m + i, j) = matrix (i, j)
  10 continue
20 continue

```

Note that when *diag* = 'U' or 'u', the elements of the array *a* corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $(k + 1)$.

x REAL for stbmv
 DOUBLE PRECISION for dtbmv
 COMPLEX for ctbmv
 DOUBLE COMPLEX for ztbmv
 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
 Before entry, the incremented array *x* must contain the *n*-element vector *x*.

incx INTEGER. Specifies the increment for the elements of *x*.
 The value of *incx* must not be zero.

Output Parameters

x Overwritten with the transformed vector *x*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbmv` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(k+1, n)$.
<i>x</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?tbsv

Solves a system of linear equations whose coefficients are in a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbsv(uplo, trans, diag, n, k, a, lda, x, incx )
call dtbsv(uplo, trans, diag, n, k, a, lda, x, incx )
call ctbsv(uplo, trans, diag, n, k, a, lda, x, incx )
call ztbsv(uplo, trans, diag, n, k, a, lda, x, incx )
```

Fortran 95:

```
call tbsv(a, x [,uplo] [, trans] [,diag])
```

Description

The ?tbsv routines solve one of the following systems of equations:

$A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$,

where:

b and *x* are *n*-element vectors,

A is an *n*-by-*n* unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is an upper or lower triangular matrix: if <i>uplo</i> = 'U' or 'u' the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the system of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{conjg}(A)*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>uplo</i> = 'U' or 'u', <i>k</i> specifies the number of super-diagonals of the matrix <i>A</i>. On entry with <i>uplo</i> = 'L' or 'l', <i>k</i> specifies the number of sub-diagonals of the matrix <i>A</i>. The value of <i>k</i> must satisfy $0 \leq k$.
<i>a</i>	REAL for stbsv DOUBLE PRECISION for dtbsv COMPLEX for ctbsv DOUBLE COMPLEX for ztbsv Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading $(k + 1)$ by <i>n</i> part of the array <i>a</i> must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row <i>k</i>, and so on. The top left <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced.

The following program segment transfers an upper triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = k + 1 - j
    do 10, i = max(1, j - k), j1
        a(m + i, j) = matrix (i, j)
    10 continue
20 continue

```

Before entry with *uplo* = 'L' or 'l', the leading $(k + 1)$ by n part of the array *a* must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array *a* is not referenced.

The following program segment transfers a lower triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min(n, j + k)
        a(m + i, j) = matrix (i, j)
    10 continue
20 continue

```

When *diag* = 'U' or 'u', the elements of the array *a* corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

lda

INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $(k + 1)$.

x

REAL for stbsv

DOUBLE PRECISION for dtbsv

COMPLEX for `ctbsv`
 DOUBLE COMPLEX for `ztbsv`
 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
 Before entry, the incremented array x must contain the
 n -element right-hand side vector b .
incx INTEGER. Specifies the increment for the elements of x .
 The value of *incx* must not be zero.

Output Parameters

x Overwritten with the solution vector x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbsv` interface are the following:

<i>a</i>	Holds the array a of size $(k+1, n)$.
x	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?tpmv

Computes a matrix-vector product using a triangular packed matrix.

Syntax

FORTRAN 77:

```
call stpmv(uplo, trans, diag, n, ap, x, incx )
call dtpmv(uplo, trans, diag, n, ap, x, incx )
call ctpmv(uplo, trans, diag, n, ap, x, incx )
call ztpmv(uplo, trans, diag, n, ap, x, incx )
```

Fortran 95:

```
call tpmv(a, x [,uplo] [, trans] [,diag])
```

Description

The ?tpmv routines perform one of the matrix-vector operations defined as

$x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $x := A * x$; if <i>trans</i> = 'T' or 't', then $x := A' * x$; if <i>trans</i> = 'C' or 'c', then $x := \text{conjg}(A') * x$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular:

	if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>ap</i>	REAL for <i>stpmv</i> DOUBLE PRECISION for <i>dtpmv</i> COMPLEX for <i>ctpmv</i> DOUBLE COMPLEX for <i>ztpmv</i> Array, DIMENSION at least $((n*(n+1))/2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(1,2) and <i>a</i>(2,2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains <i>a</i>(1,1), <i>ap</i>(2) and <i>ap</i>(3) contain <i>a</i>(2,1) and <i>a</i>(3,1) respectively, and so on. When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced, but are assumed to be unity.
<i>x</i>	REAL for <i>stpmv</i> DOUBLE PRECISION for <i>dtpmv</i> COMPLEX for <i>ctpmv</i> DOUBLE COMPLEX for <i>ztpmv</i> Array, DIMENSION at least $(1 + (n-1)*abs(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the transformed vector <i>x</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tpmv` interface are the following:

<code>a</code>	Holds the array <code>a</code> of size $(n * (n+1) / 2)$.
<code>x</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<code>diag</code>	Must be 'N' or 'U'. The default value is 'N'.

?tpsv

Solves a system of linear equations whose coefficients are in a triangular packed matrix.

Syntax

FORTRAN 77:

```
call stpsv(uplo, trans, diag, n, ap, x, incx )
call dtpsv(uplo, trans, diag, n, ap, x, incx )
call ctpsv(uplo, trans, diag, n, ap, x, incx )
call ztpsv(uplo, trans, diag, n, ap, x, incx )
```

Fortran 95:

```
call tpsv(a, x [,uplo] [, trans] [,diag])
```

Description

The `?tpsv` routines solve one of the following systems of equations

$A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$,

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

This routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the system of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{conjg}(A')*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.
<i>ap</i>	REAL for stpsv DOUBLE PRECISION for dtpsv COMPLEX for ctpsv DOUBLE COMPLEX for ztpsv Array, DIMENSION at least $((n*(n+1))/2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains $a(1, +1)$, <i>ap</i>(2) and <i>ap</i>(3) contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular matrix packed sequentially, column-by-column, so that <i>ap</i>(1) contains $a(1, +1)$, <i>ap</i>(2) and <i>ap</i>(3) contain $a(2, +1)$ and $a(3, +1)$ respectively, and so on. When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced, but are assumed to be unity.
<i>x</i>	REAL for stpsv DOUBLE PRECISION for dtpsv COMPLEX for ctpsv DOUBLE COMPLEX for ztpsv

Array, `DIMENSION` at least $(1 + (n - 1) * \text{abs}(incx))$.
 Before entry, the incremented array `x` must contain the
 n -element right-hand side vector `b`.

`incx` INTEGER. Specifies the increment for the elements of `x`.
 The value of `incx` must not be zero.

Output Parameters

`x` Overwritten with the solution vector `x`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tpsv` interface are the following:

<code>a</code>	Holds the array <code>a</code> of size $(n * (n + 1) / 2)$.
<code>x</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<code>diag</code>	Must be 'N' or 'U'. The default value is 'N'.

?trmv

Computes a matrix-vector product using a triangular matrix.

Syntax

FORTRAN 77:

```
call strmv(uplo, trans, diag, n, a, lda, x, incx )
call dtrmv(uplo, trans, diag, n, a, lda, x, incx )
call ctrmv(uplo, trans, diag, n, a, lda, x, incx )
call ztrmv(uplo, trans, diag, n, a, lda, x, incx )
```

Fortran 95:

```
call trmv(a, x [,uplo] [, trans] [,diag])
```

Description

The ?trmv routines perform one of the following matrix-vector operations defined as

$x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $x := A*x$; if <i>trans</i> = 'T' or 't', then $x := A'*x$; if <i>trans</i> = 'C' or 'c', then $x := \text{conjg}(A')*x$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>a</i>	REAL for strmv DOUBLE PRECISION for dtrmv COMPLEX for ctrmv DOUBLE COMPLEX for ztrmv Array, DIMENSION (<i>lda</i> , n). Before entry with <i>uplo</i> = 'U' or 'u', the leading n -by- n upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry

	with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>a</i> is not referenced. When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced either, but are assumed to be unity.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	REAL for <i>strmv</i> DOUBLE PRECISION for <i>dtrmv</i> COMPLEX for <i>ctrmv</i> DOUBLE COMPLEX for <i>ztrmv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the transformed vector <i>x</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trmv* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>x</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?trsv

Solves a system of linear equations whose coefficients are in a triangular matrix.

Syntax

FORTRAN 77:

```
call strsv(uplo, trans, diag, n, a, lda, x, incx )
call dtrsv(uplo, trans, diag, n, a, lda, x, incx )
call ctrsv(uplo, trans, diag, n, a, lda, x, incx )
call ztrsv(uplo, trans, diag, n, a, lda, x, incx )
```

Fortran 95:

```
call trsv(a, x [,uplo] [, trans] [,diag])
```

Description

The ?trsv routines solve one of the systems of equations:

$A*x = b$, or $A'^*x = b$, or $\text{conjg}(A')*x = b$,

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the systems of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'^*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{conjg}(A')*x = b$.

<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>a</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>a</i>	REAL for strsv DOUBLE PRECISION for dtrsv COMPLEX for ctrsv DOUBLE COMPLEX for ztrsv Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>a</i> is not referenced. When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced either, but are assumed to be unity.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	REAL for strsv DOUBLE PRECISION for dtrsv COMPLEX for ctrsv DOUBLE COMPLEX for ztrsv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element right-hand side vector <i>b</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the solution vector <i>x</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsv` interface are the following:

<i>a</i>	Holds the matrix <i>a</i> of size (n,n) .
<i>x</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

BLAS Level 3 Routines

BLAS Level 3 routines perform matrix-matrix operations. [Table 2-3](#) lists the BLAS Level 3 routine groups and the data types associated with them.

Table 2-3 BLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
?gemm	s, d, c, z	Matrix-matrix product of general matrices
?hemm	c, z	Matrix-matrix product of Hermitian matrices
?herk	c, z	Rank-k update of Hermitian matrices
?her2k	c, z	Rank-2k update of Hermitian matrices
?symm	s, d, c, z	Matrix-matrix product of symmetric matrices
?syrk	s, d, c, z	Rank-k update of symmetric matrices
?symm	s, d, c, z	Rank-2k update of symmetric matrices
?trmm	s, d, c, z	Matrix-matrix product of triangular matrices
?trsm	s, d, c, z	Linear matrix-matrix solution for triangular matrices

Symmetric Multiprocessing Version of Intel® MKL

Many applications spend considerable time for executing BLAS level 3 routines. This time can be scaled by the number of processors available on the system through using the symmetric multiprocessing(SMP) feature built into the Intel MKL Library. The performance enhancements based on the parallel use of the processors are available without any programming effort on your part.

To enhance performance, the library uses the following methods:

- The operation of BLAS level 3 matrix-matrix functions permits to restructure the code in a way which increases the localization of data reference, enhances cache memory use, and reduces the dependency on the memory bus.
- Once the code has been effectively blocked as described above, one of the matrices is distributed across the processors to be multiplied by the second matrix. Such distribution ensures effective cache management which reduces the dependency on the memory bus performance and brings good scaling results.

?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call sgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call dgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call cgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call gemm(a, b, c [,transa][,transb] [,alpha][,beta])
```

Description

The ?gemm routines perform a matrix-matrix operation with general matrices. The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$, or $\text{op}(x) = \text{conjg}(x')$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

Input Parameters

<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.
<i>transb</i>	CHARACTER*1. Specifies the form of $\text{op}(B)$ used in the matrix multiplication: if <i>transb</i> = 'N' or 'n', then $\text{op}(B) = B$; if <i>transb</i> = 'T' or 't', then $\text{op}(B) = B'$; if <i>transb</i> = 'C' or 'c', then $\text{op}(B) = \text{conjg}(B')$.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm DOUBLE COMPLEX for zgemm Specifies the scalar <i>alpha</i>.
<i>a</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm

	DOUBLE COMPLEX for zgemm Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>transa</i> = 'N' or 'n', and is <i>m</i> otherwise. Before entry with <i>transa</i> = 'N' or 'n', the leading <i>m</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i>.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>transa</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>b</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm DOUBLE COMPLEX for zgemm Array, DIMENSION (<i>ldb</i>, <i>kb</i>), where <i>kb</i> is <i>n</i> when <i>transb</i> = 'N' or 'n', and is <i>k</i> otherwise. Before entry with <i>transb</i> = 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>n</i>-by-<i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. When <i>transb</i> = 'N' or 'n', then <i>ldb</i> must be at least $\max(1, k)$, otherwise <i>ldb</i> must be at least $\max(1, n)$.
<i>beta</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm DOUBLE COMPLEX for zgemm Specifies the scalar <i>beta</i>. When <i>beta</i> is equal to zero, then <i>c</i> need not be set on input.
<i>c</i>	REAL for sgemm DOUBLE PRECISION for dgemm COMPLEX for cgemm DOUBLE COMPLEX for zgemm Array, DIMENSION (<i>ldc</i>, <i>n</i>). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>, except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.

ldc INTEGER. Specifies the first dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, m)$.

Output Parameters

c Overwritten by the *m*-by-*n* matrix $(\alpha * \text{op}(A) * \text{op}(B) + \beta * C)$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gemm` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m_a, k_a) where $k_a = k$ if <i>transa</i> = 'N', $k_a = m$ otherwise, $m_a = m$ if <i>transa</i> = 'N', $m_a = k$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (m_b, k_b) where $k_b = n$ if <i>transb</i> = 'N', $k_b = k$ otherwise, $m_b = k$ if <i>transb</i> = 'N', $m_b = n$ otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (m, n) .
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>transb</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?gemm3m

Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call cgemm3m(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zgemm3m(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call gemm3m(a, b, c [,transa][,transb] [,alpha][,beta])
```

Description

The ?gemm3m routines perform a matrix-matrix operation with general complex matrices. These routines are similar to the ?gemm routines, but they used matrix multiplications (see *Application Notes* below).

The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$, or $\text{op}(x) = \text{conjg}(x')$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

Input Parameters

<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$;

<i>transb</i>	if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$. CHARACTER*1. Specifies the form of $\text{op}(B)$ used in the matrix multiplication: if <i>transb</i> = 'N' or 'n', then $\text{op}(B) = B$; if <i>transb</i> = 'T' or 't', then $\text{op}(B) = B'$; if <i>transb</i> = 'C' or 'c', then $\text{op}(B) = \text{conjg}(B')$.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix <i>C</i>. The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero.
<i>alpha</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Specifies the scalar <i>alpha</i>.
<i>a</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>transa</i> = 'N' or 'n', and is <i>m</i> otherwise. Before entry with <i>transa</i> = 'N' or 'n', the leading <i>m</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i>.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>transa</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>b</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Array, DIMENSION (<i>ldb</i>, <i>kb</i>), where <i>kb</i> is <i>n</i> when <i>transb</i> = 'N' or 'n', and is <i>k</i> otherwise. Before entry with <i>transb</i> = 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>n</i>-by-<i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i>.

<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. When <i>transb</i> = 'N' or 'n', then <i>ldb</i> must be at least $\max(1, k)$, otherwise <i>ldb</i> must be at least $\max(1, n)$.
<i>beta</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>c</i> need not be set on input.
<i>c</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Array, DIMENSION (<i>ldc</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> matrix $(\alpha * \text{op}(A) * \text{op}(B) + \beta * C)$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gemm3m* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>ma</i> , <i>ka</i>) where <i>ka</i> = <i>k</i> if <i>transa</i> = 'N', <i>ka</i> = <i>m</i> otherwise, <i>ma</i> = <i>m</i> if <i>transa</i> = 'N', <i>ma</i> = <i>k</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>mb</i> , <i>kb</i>) where <i>kb</i> = <i>n</i> if <i>transb</i> = 'N', <i>kb</i> = <i>k</i> otherwise,

	$mb = k$ if $transb = 'N'$, $mb = n$ otherwise.
c	Holds the matrix c of size (m,n) .
$transa$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$transb$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$alpha$	The default value is 1.
$beta$	The default value is 1.

Application Notes

These routines perform the complex multiplication by forming the real and imaginary parts of the input matrices. It allows to use three real matrix multiplications and five real matrix additions, instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications only gives a 25% reduction of time in matrix operations. This can result in significant savings in computing time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

$$fl(x \text{ op } y) = (x \text{ op } y) (1 + \delta), |\delta| \leq u, \text{ op} = +, -, fl(x \pm y) = (x \pm y) (1 + \alpha) \pm y (1 + \beta), |\alpha|, |\beta| \leq u$$

then for n -by- n matrix $\hat{C} = fl(C_1 + iC_2) = fl((A_1 + iA_2)(B_1 + iB_2)) = \hat{C}_1 + i\hat{C}_2$ the following estimations are correct

$$\|\hat{C}_1 - C_2\| \leq 2(n+1)u\|A\|_{\infty}\|B\|_{\infty} + O(u^2),$$

$$\|\hat{C}_2 - C_1\| \leq 4(n+4)u\|A\|_{\infty}\|B\|_{\infty} + O(u^2),$$

$$\text{where } \|A\|_{\infty} = \max(\|A_1\|_{\infty}, \|A_2\|_{\infty}), \text{ and } \|B\|_{\infty} = \max(\|B_1\|_{\infty}, \|B_2\|_{\infty}).$$

and hence the matrix multiplications are stable.

?hemm

Computes a scalar-matrix-matrix product (either one of the matrices is Hermitian) and adds the result to scalar-matrix product.

Syntax

FORTRAN 77:

```
call chemm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc )
call zhemm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc )
```

Fortran 95:

```
call hemm(a, b, c [,side][,uplo] [,alpha][,beta])
```

Description

The ?hemm routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * B * A + \beta * C,$$

where:

α and β are scalars,

A is an Hermitian matrix,

B and C are m -by- n matrices.

Input Parameters

<i>side</i>	CHARACTER*1. Specifies whether the Hermitian matrix A appears on the left or right in the operation as follows: if $side = 'L'$ or $'l'$, then $C := \alpha * A * B + \beta * C$; if $side = 'R'$ or $'r'$, then $C := \alpha * B * A + \beta * C$.
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix A is used: If $uplo = 'U'$ or $'u'$, then the upper triangular part of the Hermitian matrix A is used.

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the Hermitian matrix <i>A</i> is used.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>C</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Array, DIMENSION (<i>lda</i> , <i>ka</i>), where <i>ka</i> is <i>m</i> when <i>side</i> = 'L' or 'l' and is <i>n</i> otherwise. Before entry with <i>side</i> = 'L' or 'l', the <i>m</i> -by- <i>m</i> part of the array <i>a</i> must contain the Hermitian matrix, such that when <i>uplo</i> = 'U' or 'u', the leading <i>m</i> -by- <i>m</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the leading <i>m</i> -by- <i>m</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of <i>a</i> is not referenced. Before entry with <i>side</i> = 'R' or 'r', the <i>n</i> -by- <i>n</i> part of the array <i>a</i> must contain the Hermitian matrix, such that when <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub) program. When <i>side</i> = 'L' or 'l' then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, n)$.

<i>b</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Array, DIMENSION (<i>ldb</i>,<i>n</i>). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.
<i>beta</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Specifies the scalar <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>c</i> need not be set on input.
<i>c</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Array, DIMENSION (<i>c</i>, <i>n</i>). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>, except when <i>beta</i> is zero, in which case <i>c</i> need not be set on entry.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hemm` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i>,<i>k</i>) where $k = m$ if <i>side</i> = 'L', $k = n$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>m</i> , <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).

<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?herk

Performs a rank- n update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cherk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc )
call zherk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc )
```

Fortran 95:

```
call herk(a, c [,uplo] [, trans] [,alpha][,beta])
```

Description

The ?herk routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * \text{conjg}(A') + \beta * C,$$

or

$$C := \alpha * \text{conjg}(A') * A + \beta * C,$$

where:

alpha and *beta* are real scalars,

C is an n -by- n Hermitian matrix,

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the array *c* is used.
If *uplo* = 'U' or 'u', then the upper triangular part of the array *c* is used.

	If <code>uplo = 'L' or 'l'</code>, then the low triangular part of the array <code>c</code> is used.
<code>trans</code>	CHARACTER*1. Specifies the operation: if <code>trans = 'N' or 'n'</code>, then <code>C:= alpha*A*conjg(A')+beta*C</code>; if <code>trans = 'C' or 'c'</code>, then <code>C:= alpha*conjg(A')*A+beta*C</code>.
<code>n</code>	INTEGER. Specifies the order of the matrix <code>C</code>. The value of <code>n</code> must be at least zero.
<code>k</code>	INTEGER. With <code>trans = 'N' or 'n'</code>, <code>k</code> specifies the number of columns of the matrix <code>A</code>, and with <code>trans = 'C' or 'c'</code>, <code>k</code> specifies the number of rows of the matrix <code>A</code>. The value of <code>k</code> must be at least zero.
<code>alpha</code>	REAL for <code>cherk</code> DOUBLE PRECISION for <code>zherk</code> Specifies the scalar <code>alpha</code>.
<code>a</code>	COMPLEX for <code>cherk</code> DOUBLE COMPLEX for <code>zherk</code> Array, DIMENSION (<code>lda</code>, <code>ka</code>), where <code>ka</code> is <code>k</code> when <code>trans = 'N' or 'n'</code>, and is <code>n</code> otherwise. Before entry with <code>trans = 'N' or 'n'</code>, the leading <code>n</code>-by-<code>k</code> part of the array <code>a</code> must contain the matrix <code>a</code>, otherwise the leading <code>k</code>-by-<code>n</code> part of the array <code>a</code> must contain the matrix <code>A</code>.
<code>lda</code>	INTEGER. Specifies the first dimension of <code>a</code> as declared in the calling (sub)program. When <code>trans = 'N' or 'n'</code>, then <code>lda</code> must be at least <code>max(1, n)</code>, otherwise <code>lda</code> must be at least <code>max(1, k)</code>.
<code>beta</code>	REAL for <code>cherk</code> DOUBLE PRECISION for <code>zherk</code> Specifies the scalar <code>beta</code>.
<code>c</code>	COMPLEX for <code>cherk</code> DOUBLE COMPLEX for <code>zherk</code> Array, DIMENSION (<code>ldc</code>,<code>n</code>).

Before entry with `uplo = 'U' or 'u'`, the leading n -by- n upper triangular part of the array `c` must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of `c` is not referenced.

Before entry with `uplo = 'L' or 'l'`, the leading n -by- n lower triangular part of the array `c` must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of `c` is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

`ldc`

INTEGER. Specifies the first dimension of `c` as declared in the calling (sub)program. The value of `ldc` must be at least $\max(1, n)$.

Output Parameters

`c`

With `uplo = 'U' or 'u'`, the upper triangular part of the array `c` is overwritten by the upper triangular part of the updated matrix.

With `uplo = 'L' or 'l'`, the lower triangular part of the array `c` is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `herk` interface are the following:

`a`

Holds the matrix `A` of size (ma, ka) where

$ka = k$ if `transa = 'N'`,

$ka = n$ otherwise,

$ma = n$ if `transa = 'N'`,

$ma = k$ otherwise.

`c`

Holds the matrix `C` of size (n, n) .

`uplo`

Must be 'U' or 'L'. The default value is 'U'.

<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?her2k

Performs a rank-2k update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zher2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call her2k(a, b, c [,uplo][,trans] [,alpha][,beta])
```

Description

The ?her2k routines perform a rank-2k matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha A * \text{conjg}(B') + \text{conjg}(\alpha) B * \text{conjg}(A') + \beta C,$$

or

$$C := \alpha * \text{conjg}(B') * A + \text{conjg}(\alpha) * \text{conjg}(A') * B + \beta C,$$

where:

alpha is a scalar and *beta* is a real scalar,

C is an *n*-by-*n* Hermitian matrix,

A and *B* are *n*-by-*k* matrices in the first case and *k*-by-*n* matrices in the second case.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>c</i> is used.

	If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * \text{conjg}(B') + \alpha * B * \text{conjg}(A') + \beta * C$; if <i>trans</i> = 'C' or 'c', then $C := \alpha * \text{conjg}(A') * B + \alpha * \text{conjg}(B') * A + \beta * C$.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. With <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i> , and with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>A</i> . The value of <i>k</i> must be at least equal to zero.
<i>alpha</i>	COMPLEX for cher2k DOUBLE COMPLEX for zher2k Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for cher2k DOUBLE COMPLEX for zher2k Array, DIMENSION (<i>lda</i> , <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>beta</i>	REAL for cher2k DOUBLE PRECISION for zher2k Specifies the scalar <i>beta</i> .
<i>b</i>	COMPLEX for cher2k DOUBLE COMPLEX for zher2k

Array, DIMENSION (ldb , kb), where kb is k when $trans = 'N'$ or $'n'$, and is n otherwise. Before entry with $trans = 'N'$ or $'n'$, the leading n -by- k part of the array b must contain the matrix B , otherwise the leading k -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the first dimension of b as declared in the calling (sub)program. When $trans = 'N'$ or $'n'$, then ldb must be at least $\max(1, n)$, otherwise ldb must be at least $\max(1, k)$.

c COMPLEX for cher2k
DOUBLE COMPLEX for zher2k
Array, DIMENSION (ldc, n).
Before entry with $uplo = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of c is not referenced.
Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of c is not referenced.
The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

ldc INTEGER. Specifies the first dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, n)$.

Output Parameters

c With $uplo = 'U'$ or $'u'$, the upper triangular part of the array c is overwritten by the upper triangular part of the updated matrix.
With $uplo = 'L'$ or $'l'$, the lower triangular part of the array c is overwritten by the lower triangular part of the updated matrix.
The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her2k` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m_a, k_a) where $k_a = k$ if <i>trans</i> = 'N', $k_a = n$ otherwise, $m_a = n$ if <i>trans</i> = 'N', $m_a = k$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (m_b, k_b) where $k_b = k$ if <i>trans</i> = 'N', $k_b = n$ otherwise, $m_b = n$ if <i>trans</i> = 'N', $m_b = k$ otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?symm

Performs a scalar-matrix-matrix product(one matrix operand is symmetric) and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call ssymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc )
call dsymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc )
call csymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc )
call zsymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc )
```

Fortran 95:

```
call symm(a, b, c [,side][,uplo] [,alpha][,beta])
```

Description

The ?`symm` routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha * A * B + \beta * C,$$

or

$$C := \alpha * B * A + \beta * C,$$

where:

alpha and *beta* are scalars,

A is a symmetric matrix,

B and *C* are *m*-by-*n* matrices.

Input Parameters

<i>side</i>	CHARACTER*1. Specifies whether the symmetric matrix <i>A</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then $C := \alpha * A * B + \beta * C$; if <i>side</i> = 'R' or 'r', then $C := \alpha * B * A + \beta * C$.
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>C</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <code>ssymm</code> DOUBLE PRECISION for <code>dsymm</code> COMPLEX for <code>csymm</code> DOUBLE COMPLEX for <code>zsymm</code> Specifies the scalar <i>alpha</i> .

<i>a</i>	REAL for ssymm DOUBLE PRECISION for dsymm COMPLEX for csymm DOUBLE COMPLEX for zsymm Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>m</i> when <i>side</i> = 'L' or 'l' and is <i>n</i> otherwise. Before entry with <i>side</i> = 'L' or 'l', the <i>m</i>-by-<i>m</i> part of the array <i>a</i> must contain the symmetric matrix, such that when <i>uplo</i> = 'U' or 'u', the leading <i>m</i>-by-<i>m</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the leading <i>m</i>-by-<i>m</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced. Before entry with <i>side</i> = 'R' or 'r', the <i>n</i>-by-<i>n</i> part of the array <i>a</i> must contain the symmetric matrix, such that when <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>side</i> = 'L' or 'l' then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, n)$.
<i>b</i>	REAL for ssymm DOUBLE PRECISION for dsymm COMPLEX for csymm DOUBLE COMPLEX for zsymm Array, DIMENSION (<i>ldb</i>, <i>n</i>). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.

<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.
<i>beta</i>	REAL for <i>ssymm</i> DOUBLE PRECISION for <i>dsymm</i> COMPLEX for <i>csymm</i> DOUBLE COMPLEX for <i>zsymm</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>c</i> need not be set on input.
<i>c</i>	REAL for <i>ssymm</i> DOUBLE PRECISION for <i>dsymm</i> COMPLEX for <i>csymm</i> DOUBLE COMPLEX for <i>zsymm</i> Array, DIMENSION (<i>ldc</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is zero, in which case <i>c</i> need not be set on entry.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *symm* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>k</i>) where <i>k</i> = <i>m</i> if <i>side</i> = 'L', <i>k</i> = <i>n</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>m</i> , <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?syrk

Performs a rank- n update of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyrk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc )
call dsyrk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc )
call csyrk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc )
call zsyrk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc )
```

Fortran 95:

```
call syrk(a, c [,uplo] [, trans] [,alpha][,beta])
```

Description

The ?syrk routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha * A * A' + \beta * C,$$

or

$$C := \alpha * A' * A + \beta * C,$$

where:

alpha and *beta* are scalars,

C is an n -by- n symmetric matrix,

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used.

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * A' + \beta * C$; if <i>trans</i> = 'T' or 't', then $C := \alpha * A' * A + \beta * C$; if <i>trans</i> = 'C' or 'c', then $C := \alpha * A' * A + \beta * C$.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>c</i>. The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>a</i>, and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>a</i>. The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk Specifies the scalar <i>alpha</i>.
<i>a</i>	REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>beta</i>	REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk Specifies the scalar <i>beta</i>.

c REAL for ssyrk
DOUBLE PRECISION for dsyrk
COMPLEX for csyrk
DOUBLE COMPLEX for zsyrk
Array, DIMENSION (*ldc*, *n*). Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *c* must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of *c* is not referenced.
Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *c* must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of *c* is not referenced.

ldc INTEGER. Specifies the first dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.
With *uplo* = 'L' or 'l', the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syrk` interface are the following:

a Holds the matrix *A* of size (*ma*, *ka*) where
 $ka = k$ if *transa* = 'N',
 $ka = n$ otherwise,
 $ma = n$ if *transa* = 'N',
 $ma = k$ otherwise.

c Holds the matrix *C* of size (*n*, *n*).

<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?syr2k

Performs a rank-2k update of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc )
call dsyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc )
call csyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc )
call zsyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc )
```

Fortran 95:

```
call syr2k(a, b, c [,uplo][,trans] [,alpha][,beta])
```

Description

The ?syr2k routines perform a rank-2k matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha A B' + \alpha B A' + \beta C,$$

or

$$C := \alpha A' B + \alpha B' A + \beta C,$$

where:

alpha and *beta* are scalars,

C is an *n*-by-*n* symmetric matrix,

A and *B* are *n*-by-*k* matrices in the first case, and *k*-by-*n* matrices in the second case.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * B' + \alpha * B * A' + \beta * C$; if <i>trans</i> = 'T' or 't', then $C := \alpha * A' * B + \alpha * B' * A + \beta * C$; if <i>trans</i> = 'C' or 'c', then $C := \alpha * A' * B + \alpha * B' * A + \beta * C$.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrices <i>A</i> and <i>B</i>, and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrices <i>A</i> and <i>B</i>. The value of <i>k</i> must be at least zero.
<i>alpha</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyr2k Specifies the scalar <i>alpha</i>.
<i>a</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyr2k Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.

<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.
<i>b</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyr2k Array, DIMENSION (<i>ldb</i>, <i>kb</i>) where <i>kb</i> is <i>k</i> when <i>trans</i> = 'N' or 'n' and is 'n' otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>ldb</i> must be at least $\max(1, n)$, otherwise <i>ldb</i> must be at least $\max(1, k)$.
<i>beta</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyr2k Specifies the scalar <i>beta</i>.
<i>c</i>	REAL for ssyr2k DOUBLE PRECISION for dsyr2k COMPLEX for csyr2k DOUBLE COMPLEX for zsyr2k Array, DIMENSION (<i>ldc</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>c</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>c</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>c</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>c</i> is not referenced.

ldc INTEGER. Specifies the first dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.
With *uplo* = 'L' or 'l', the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syr2k* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (ma, ka) where $ka = k$ if <i>trans</i> = 'N', $ka = n$ otherwise, $ma = n$ if <i>trans</i> = 'N', $ma = k$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (mb, kb) where $kb = k$ if <i>trans</i> = 'N', $kb = n$ otherwise, $mb = n$ if <i>trans</i> = 'N', $mb = k$ otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 1.

?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular).

Syntax

FORTRAN 77:

```
call strmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
call dtrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
call ctrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
call ztrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
```

Fortran 95:

```
call trmm(a, b [,side] [, uplo] [,transa][,diag] [,alpha])
```

Description

The ?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

$B := \alpha * \text{op}(A) * B$

or

$B := \alpha * B * \text{op}(A)$

where:

α is a scalar,

B is an m -by- n matrix,

A is a unit, or non-unit, upper or lower triangular matrix

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A'$, or $\text{op}(A) = \text{conjg}(A')$.

Input Parameters

<i>side</i>	CHARACTER*1. Specifies whether $\text{op}(A)$ appears on the left or right of B in the operation: if <i>side</i> = 'L' or 'l', then $B := \alpha * \text{op}(A) * B$; if <i>side</i> = 'R' or 'r', then $B := \alpha * B * \text{op}(A)$.

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	INTEGER. Specifies the number of rows of <i>B</i>. The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of <i>B</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>strmm</i> DOUBLE PRECISION for <i>dtrmm</i> COMPLEX for <i>ctrmm</i> DOUBLE COMPLEX for <i>ztrmm</i> Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	REAL for <i>strmm</i> DOUBLE PRECISION for <i>dtrmm</i> COMPLEX for <i>ctrmm</i> DOUBLE COMPLEX for <i>ztrmm</i> Array, DIMENSION (<i>lda</i>,<i>k</i>), where <i>k</i> is <i>m</i> when <i>side</i> = 'L' or 'l' and is <i>n</i> when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>k</i> by <i>k</i> upper triangular part of the array <i>a</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>k</i> by <i>k</i> lower triangular part of the array <i>a</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>a</i> is not referenced.

	When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced either, but are assumed to be unity.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>side</i> = 'L' or 'l', then <i>lda</i> must be at least $\max(1, m)$, when <i>side</i> = 'R' or 'r', then <i>lda</i> must be at least $\max(1, n)$.
<i>b</i>	REAL for <i>strmm</i> DOUBLE PRECISION for <i>dtrmm</i> COMPLEX for <i>ctrmm</i> DOUBLE COMPLEX for <i>ztrmm</i> Array, DIMENSION (<i>ldb</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.

Output Parameters

<i>b</i>	Overwritten by the transformed matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trmm* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>k</i>) where <i>k</i> = <i>m</i> if <i>side</i> = 'L', <i>k</i> = <i>n</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

alpha

The default value is 1.

?trsm

Solves a matrix equation (one matrix operand is triangular).

Syntax

FORTRAN 77:

```
call strsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
call dtrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
call ctrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
call ztrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb )
```

Fortran 95:

```
call trsm(a, b [,side] [, uplo] [,transa][,diag] [,alpha])
```

Description

The ?trsm routines solve one of the following matrix equations:

$$\text{op}(A) * X = \alpha * B,$$

or

$$X * \text{op}(A) = \alpha * B,$$

where:

alpha is a scalar,

X and *B* are *m*-by-*n* matrices,

A is a unit, or non-unit, upper or lower triangular matrix

op(*A*) is one of *op*(*A*) = *A*, or *op*(*A*) = *A'*, or *op*(*A*) = *conjg*(*A'*).

The matrix *B* is overwritten by the solution matrix *X*.

Input Parameters

side

CHARACTER*1. Specifies whether *op*(*A*) appears on the left or right of *X* in the equation:

	if <i>side</i> = 'L' or 'l', then $\text{op}(A) * X = \alpha * B$; if <i>side</i> = 'R' or 'r', then $X * \text{op}(A) = \alpha * B$.
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A)$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	INTEGER. Specifies the number of rows of <i>B</i>. The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of <i>B</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>strsm</i> DOUBLE PRECISION for <i>dtrsm</i> COMPLEX for <i>ctrsm</i> DOUBLE COMPLEX for <i>ztrsm</i> Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	REAL for <i>strsm</i> DOUBLE PRECISION for <i>dtrsm</i> COMPLEX for <i>ctrsm</i> DOUBLE COMPLEX for <i>ztrsm</i> Array, DIMENSION (<i>lda</i>, <i>k</i>), where <i>k</i> is <i>m</i> when <i>side</i> = 'L' or 'l' and is <i>n</i> when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>k</i> by <i>k</i> upper triangular part of the array <i>a</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>a</i> is not referenced.

Before entry with *uplo* = 'L' or 'l', the leading *k* by *k* lower triangular part of the array *a* must contain the lower triangular matrix and the strictly upper triangular part of *a* is not referenced.

When *diag* = 'U' or 'u', the diagonal elements of *a* are not referenced either, but are assumed to be unity.

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. When *side* = 'L' or 'l', then *lda* must be at least $\max(1, m)$, when *side* = 'R' or 'r', then *lda* must be at least $\max(1, n)$.

b REAL for *strsm*
DOUBLE PRECISION for *dtrsm*
COMPLEX for *ctrsm*
DOUBLE COMPLEX for *ztrsm*
Array, DIMENSION (*ldb*, *n*). Before entry, the leading *m*-by-*n* part of the array *b* must contain the right-hand side matrix *B*.

ldb INTEGER. Specifies the first dimension of *b* as declared in the calling (sub)program. The value of *ldb* must be at least $\max(1, +m)$.

Output Parameters

b Overwritten by the solution matrix *X*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trsm* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>k</i>) where <i>k</i> = <i>m</i> if <i>side</i> = 'L', <i>k</i> = <i>n</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>transa</i>	Must be 'N', 'C', or 'T'.

	The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.
<i>alpha</i>	The default value is 1.

Sparse BLAS Level 1 Routines

This section describes Sparse BLAS Level 1, an extension of BLAS Level 1 included in the Intel® Math Kernel Library beginning with the Intel MKL release 2.1. Sparse BLAS Level 1 is a group of routines and functions that perform a number of common vector operations on sparse vectors stored in compressed form.

Sparse vectors are those in which the majority of elements are zeros. Sparse BLAS routines and functions are specially implemented to take advantage of vector sparsity. This allows you to achieve large savings in computer time and memory. If nz is the number of non-zero vector elements, the computer time taken by Sparse BLAS operations will be $O(nz)$.

Vector Arguments

Compressed sparse vectors. Let a be a vector stored in an array, and assume that the only non-zero elements of a are the following:

$a(k_1), a(k_2), a(k_3) \dots a(k_{nz}),$

where nz is the total number of non-zero elements in a .

In Sparse BLAS, this vector can be represented in compressed form by two FORTRAN arrays, x (values) and $indx$ (indices). Each array has nz elements:

$x(1)=a(k_1), x(2)=a(k_2), \dots x(nz)=a(k_{nz}),$

$indx(1)=k_1, indx(2)=k_2, \dots indx(nz)=k_{nz}.$

Thus, a sparse vector is fully determined by the triple $(nz, x, indx)$. If you pass a negative or zero value of nz to Sparse BLAS, the subroutines do not modify any arrays or variables.

Full-storage vectors. Sparse BLAS routines can also use a vector argument fully stored in a single FORTRAN array (a full-storage vector). If y is a full-storage vector, its elements must be stored contiguously: the first element in $y(1)$, the second in $y(2)$, and so on. This corresponds to an increment $incy = 1$ in BLAS Level 1. No increment value for full-storage vectors is passed as an argument to Sparse BLAS routines or functions.

Naming Conventions

Similar to BLAS, the names of Sparse BLAS subprograms have prefixes that determine the data type involved: *s* and *d* for single- and double-precision real; *c* and *z* for single- and double-precision complex respectively.

If a Sparse BLAS routine is an extension of a “dense” one, the subprogram name is formed by appending the suffix *i* (standing for *indexed*) to the name of the corresponding “dense” subprogram. For example, the Sparse BLAS routine `saxpyi` corresponds to the BLAS routine `saxpy`, and the Sparse BLAS function `cdotci` corresponds to the BLAS function `cdotc`.

Routines and Data Types

Routines and data types supported in the Intel MKL implementation of Sparse BLAS are listed in Table 2-4 .

Table 2-4 Sparse BLAS Routines and Their Data Types

Routine/Function	Data Types	Description
?axpyi	s, d, c, z	Scalar-vector product plus vector (routines)
?doti	s, d	Dot product (functions)
?dotci	c, z	Complex dot product conjugated (functions)
?dotui	c, z	Complex dot product unconjugated (functions)
?gthr	s, d, c, z	Gathering a full-storage sparse vector into compressed form <i>nz</i> , <i>x</i> , <i>indx</i> (routines)
?gthrz	s, d, c, z	Gathering a full-storage sparse vector into compressed form and assigning zeros to gathered elements in the full-storage vector (routines)
?roti	s, d	Givens rotation (routines)
?sctr	s, d, c, z	Scattering a vector from compressed form to full-storage form (routines)

BLAS Level 1 Routines That Can Work With Sparse Vectors

The following BLAS Level 1 routines will give correct results when you pass to them a compressed-form array x (with the increment $incx=1$):

<code>?asum</code>	sum of absolute values of vector elements
<code>?copy</code>	copying a vector
<code>?nrm2</code>	Euclidean norm of a vector
<code>?scal</code>	scaling a vector
<code>i?amax</code>	index of the element with the largest absolute value for real flavors, or the largest sum $ Re(x(i)) + Im(x(i)) $ for complex flavors.
<code>i?amin</code>	index of the element with the smallest absolute value for real flavors, or the smallest sum $ Re(x(i)) + Im(x(i)) $ for complex flavors.

The result i returned by `i?amax` and `i?amin` should be interpreted as index in the compressed-form array, so that the largest (smallest) value is $x(i)$; the corresponding index in full-storage array is $indx(i)$.

You can also call `?roti` to compute the parameters of Givens rotation and then pass these parameters to the Sparse BLAS routines `?roti`.

`?axpyi`

Adds a scalar multiple of compressed sparse vector to a full-storage vector.

Syntax

FORTRAN 77:

```
call saxpyi(nz, a, x, indx, y)
call daxpyi(nz, a, x, indx, y)
call caxpyi(nz, a, x, indx, y)
call zaxpyi(nz, a, x, indx, y)
```

Fortran 95:

```
call axpyi(x, indx, y [, a])
```

Description

The ?axpyi routines perform a vector-vector operation defined as

$$y := a * x + y$$

where:

a is a scalar,

x is a sparse vector stored in compressed form,

y is a vector in full storage form.

The ?axpyi routines reference or modify only the elements of y whose indices are listed in the array $indx$.

The values in $indx$ must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and $indx$.
a	REAL for saxpyi DOUBLE PRECISION for daxpyi COMPLEX for caxpyi DOUBLE COMPLEX for zaxpyi Specifies the scalar a .
x	REAL for saxpyi DOUBLE PRECISION for daxpyi COMPLEX for caxpyi DOUBLE COMPLEX for zaxpyi Array, DIMENSION at least nz .
$indx$	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	REAL for saxpyi DOUBLE PRECISION for daxpyi COMPLEX for caxpyi DOUBLE COMPLEX for zaxpyi Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

y	Contains the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpyi` interface are the following:

<code>x</code>	Holds the vector of length (<code>nz</code>).
<code>indx</code>	Holds the vector of length (<code>nz</code>).
<code>y</code>	Holds the vector of length (<code>nz</code>).
<code>a</code>	The default value is 1.

?doti

Computes the dot product of a compressed sparse real vector by a full-storage real vector.

Syntax

FORTRAN 77:

```
res = sdoti(nz, x, indx, y )
res = ddoti(nz, x, indx, y )
```

Fortran 95:

```
res = doti(x, indx, y)
```

Description

The `?doti` functions return the dot product of `x` and `y` defined as

$$\text{res} = x(1)*y(\text{indx}(1)) + x(2)*y(\text{indx}(2)) + \dots + x(nz)*y(\text{indx}(nz))$$

where the triple (`nz`, `x`, `indx`) defines a sparse real vector stored in compressed form, and `y` is a real vector in full storage form. The functions reference only the elements of `y` whose indices are listed in the array `indx`. The values in `indx` must be distinct.

Input Parameters

<code>nz</code>	INTEGER. The number of elements in <code>x</code> and <code>indx</code> .
<code>x</code>	REAL for <code>sdoti</code>

`DOUBLE PRECISION` for `ddoti`
 Array, `DIMENSION` at least `nz`.

`indx` `INTEGER`. Specifies the indices for the elements of `x`.
 Array, `DIMENSION` at least `nz`.

`y` `REAL` for `sdoti`
 `DOUBLE PRECISION` for `ddoti`
 Array, `DIMENSION` at least `max(indx(i))`.

Output Parameters

`res` `REAL` for `sdoti`
 `DOUBLE PRECISION` for `ddoti`
 Contains the dot product of `x` and `y`, if `nz` is positive.
 Otherwise, `res` contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `doti` interface are the following:

`x` Holds the vector of length (`nz`).

`indx` Holds the vector of length (`nz`).

`y` Holds the vector of length (`nz`).

?dotci

Computes the conjugated dot product of a compressed sparse complex vector with a full-storage complex vector.

Syntax

FORTRAN 77:

```
res = cdotci(nz, x, indx, y )
res = zdotci(nz, x, indx, y )
```

Fortran 95:

```
res = dotci(x, indx, y)
```

Description

The `?dotci` functions return the dot product of x and y defined as

$$\text{conjg}(x(1)) * y(\text{indx}(1)) + \dots + \text{conjg}(x(nz)) * y(\text{indx}(nz))$$

where the triple (nz, x, indx) defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array indx . The values in indx must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and indx .
x	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Array, DIMENSION at least nz .
indx	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Array, DIMENSION at least $\max(\text{indx}(i))$.

Output Parameters

res	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Contains the conjugated dot product of x and y , if nz is positive. Otherwise, res contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotci` interface are the following:

x	Holds the vector of length (nz) .
indx	Holds the vector of length (nz) .

y Holds the vector of length (nz).

?dotui

Computes the dot product of a compressed sparse complex vector by a full-storage complex vector.

Syntax

FORTRAN 77:

```
res = cdotui(nz, x, indx, y )
```

```
res = zdotui(nz, x, indx, y )
```

Fortran 95:

```
res = dotui(x, indx, y)
```

Description

The ?dotui functions return the dot product of x and y defined as

$$res = x(1)*y(indx(1)) + x(2)*y(indx(2)) + \dots + x(nz)*y(indx(nz))$$

where the triple ($nz, x, indx$) defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and $indx$.
x	COMPLEX for cdotui DOUBLE COMPLEX for zdotui Array, DIMENSION at least nz .
$indx$	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	COMPLEX for cdotui DOUBLE COMPLEX for zdotui Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

<code>res</code>	COMPLEX for <code>cdotui</code> DOUBLE COMPLEX for <code>zdotui</code> Contains the dot product of x and y , if nz is positive. Otherwise, <code>res</code> contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotui` interface are the following:

x	Holds the vector of length (nz).
<code>indx</code>	Holds the vector of length (nz).
y	Holds the vector of length (nz).

?gthr

Gathers a full-storage sparse vector's elements into compressed form.

Syntax

FORTRAN 77:

```
call sgthr(nz, y, x, indx )
call dgthr(nz, y, x, indx )
call cgthr(nz, y, x, indx )
call zgthr(nz, y, x, indx )
```

Fortran 95:

```
res = gthr(x, indx, y)
```

Description

The `?gthr` routines gather the specified elements of a full-storage sparse vector y into compressed form($nz, x, indx$). The routines reference only the elements of y whose indices are listed in the array `indx`:

$x(i) = y(indx(i))$, for $i=1, 2, \dots, +nz$.

Input Parameters

nz INTEGER. The number of elements of *y* to be gathered.

indx INTEGER. Specifies indices of elements to be gathered.
Array, DIMENSION at least *nz*.

y REAL for sgthr
DOUBLE PRECISION for dgthr
COMPLEX for cgthr
DOUBLE COMPLEX for zgthr
Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

x REAL for sgthr
DOUBLE PRECISION for dgthr
COMPLEX for cgthr
DOUBLE COMPLEX for zgthr
Array, DIMENSION at least *nz*.
Contains the vector converted to the compressed form.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gthr* interface are the following:

x Holds the vector of length (*nz*).

indx Holds the vector of length (*nz*).

y Holds the vector of length (*nz*).

?gthrz

Gathers a sparse vector's elements into compressed form, replacing them by zeros.

Syntax

FORTRAN 77:

```
call sgthrz(nz, y, x, indx )
call dgthrz(nz, y, x, indx )
call cgthrz(nz, y, x, indx )
call zgthrz(nz, y, x, indx )
```

Fortran 95:

```
res = gthrz(x, indx, y)
```

Description

The ?gthrz routines gather the elements with indices specified by the array *indx* from a full-storage vector *y* into compressed form (*nz*, *x*, *indx*) and overwrite the gathered elements of *y* by zeros. Other elements of *y* are not referenced or modified (see also ?gthr).

Input Parameters

<i>nz</i>	INTEGER. The number of elements of <i>y</i> to be gathered.
<i>indx</i>	INTEGER. Specifies indices of elements to be gathered. Array, DIMENSION at least <i>nz</i> .
<i>y</i>	REAL for sgthrz DOUBLE PRECISION for dgthrz COMPLEX for cgthrz DOUBLE COMPLEX for zgthrz Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

<i>x</i>	REAL for sgthrz DOUBLE PRECISION for dgthrz COMPLEX for cgthrz DOUBLE COMPLEX for zgthrz

	Array, <code>DIMENSION</code> at least <code>nz</code> .
	Contains the vector converted to the compressed form.
<code>y</code>	The updated vector <code>y</code> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gthrz` interface are the following:

<code>x</code>	Holds the vector of length (<code>nz</code>).
<code>indx</code>	Holds the vector of length (<code>nz</code>).
<code>y</code>	Holds the vector of length (<code>nz</code>).

?roti

Applies Givens rotation to sparse vectors one of which is in compressed form.

Syntax

FORTRAN 77:

```
call sroti(nz, x, indx, y, c, s)
call droti(nz, x, indx, y, c, s)
```

Fortran 95:

```
call roti(x, indx, y [, c] [,s])
```

Description

The `?roti` routines apply the Givens rotation to elements of two real vectors, `x` (in compressed form `nz, x, indx`) and `y` (in full storage form):

$$x(i) = c*x(i) + s*y(indx(i))$$

$$y(indx(i)) = c*y(indx(i)) - s*x(i)$$

The routines reference only the elements of `y` whose indices are listed in the array `indx`. The values in `indx` must be distinct.

Input Parameters

<i>nz</i>	INTEGER. The number of elements in <i>x</i> and <i>indx</i> .
<i>x</i>	REAL for <code>sroti</code> DOUBLE PRECISION for <code>droti</code> Array, DIMENSION at least <i>nz</i> .
<i>indx</i>	INTEGER. Specifies the indices for the elements of <i>x</i> . Array, DIMENSION at least <i>nz</i> .
<i>y</i>	REAL for <code>sroti</code> DOUBLE PRECISION for <code>droti</code> Array, DIMENSION at least $\max(\text{indx}(i))$.
<i>c</i>	A scalar: REAL for <code>sroti</code> DOUBLE PRECISION for <code>droti</code> .
<i>s</i>	A scalar: REAL for <code>sroti</code> DOUBLE PRECISION for <code>droti</code> .

Output Parameters

<i>x</i> and <i>y</i>	The updated arrays.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `roti` interface are the following:

<i>x</i>	Holds the vector of length (<i>nz</i>).
<i>indx</i>	Holds the vector of length (<i>nz</i>).
<i>y</i>	Holds the vector of length (<i>nz</i>).
<i>c</i>	The default value is 1.
<i>s</i>	The default value is 1.

?sctr

Converts compressed sparse vectors into full storage form.

Syntax

FORTRAN 77:

```
call ssctr(nz, x, indx, y )
call dsctr(nz, x, indx, y )
call csctr(nz, x, indx, y )
call zsctr(nz, x, indx, y )
```

Fortran 95:

```
call sctr(x, indx, y)
```

Description

The ?sctr routines scatter the elements of the compressed sparse vector ($nz, x, indx$) to a full-storage vector y . The routines modify only the elements of y whose indices are listed in the array $indx$:

$y(indx(i)) = x(i), \text{ for } i=1, 2, \dots, +nz.$

Input Parameters

nz	INTEGER. The number of elements of x to be scattered.
$indx$	INTEGER. Specifies indices of elements to be scattered. Array, DIMENSION at least nz .
x	REAL for ssctr DOUBLE PRECISION for dsctr COMPLEX for csctr DOUBLE COMPLEX for zsctr Array, DIMENSION at least nz . Contains the vector to be converted to full-storage form.

Output Parameters

y	REAL for ssctr

DOUBLE PRECISION for dsctr
 COMPLEX for csctr
 DOUBLE COMPLEX for zsctr
 Array, DIMENSION at least $\max(\text{indx}(i))$.
 Contains the vector y with updated elements.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sctr` interface are the following:

x	Holds the vector of length (nz) .
$indx$	Holds the vector of length (nz) .
y	Holds the vector of length (nz) .

Sparse BLAS Level 2 and Level 3 Routines

This section describes Sparse BLAS Level 2 and Level 3 routines included in the Intel® Math Kernel Library (Intel® MKL) . Sparse BLAS Level 2 is a group of routines and functions that perform operations between a sparse matrix and dense vectors. Sparse BLAS Level 3 is a group of routines and functions that perform operations between a sparse matrix and dense matrices.

The terms and concepts required to understand the use of the Intel MKL Sparse BLAS Level 2 and Level 3 routines are discussed in the [Linear Solvers Basics](#) appendix.

This Sparse BLAS routines can be useful to implement iterative methods for solving large sparse systems of equations or eigenvalue problems. For example, these routines can be considered as building blocks for “[Iterative Sparse Solvers based on Reverse Communication Interface \(RCI ISS\)](#)” described in the Chapter 8 of the manual.

Intel MKL provides Sparse BLAS Level 2 and Level 3 routines with typical (or conventional) interface similar to the interface used in the NIST* Sparse BLAS library [[Rem05](#)].

Some software packages and libraries (the [PARDISO* Solver](#) used in Intel MKL, *Sparskit 2* [[Saad94](#)], the Compaq* Extended Math Library (CXML)[[CXML01](#)]) use different (early) variation of the compressed sparse row (CSR) format and support only Level 2 operations with simplified interfaces. Intel MKL provides an additional set of Sparse BLAS Level 2 routines with similar simplified interfaces. Each of these routines operates only on a matrix of the fixed type.

The routines described in this section support both one-based indexing and zero-based indexing of the input data (see details in the section [One-based and Zero-based Indexing](#)).

Naming Conventions in Sparse BLAS Level 2 and Level 3

Each Sparse BLAS Level 2 and Level 3 routine has a six- or eight-character base name preceded by the prefix `mkl_` or `mkl_cspblas_`.

The routines with typical (conventional) interface have six-character base names in accordance with the template:

```
mkl_<character> <data> <operation>( )
```

The routines with simplified interfaces have eight-character base names in accordance with the templates:

```
mkl_<character> <data> <mtype> <operation>( )
```

for routines with one-based indexing; and

```
mkl_cspblas_<character> <data> <mtype> <operation>( )
```

for routines with zero-based indexing.

The `<character>` field indicates the data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision

The `<data>` field indicates the sparse matrix storage format (see section [Sparse Matrix Storage Formats](#)):

coo	coordinate format
csr	compressed sparse row format and its variations
csc	compressed sparse column format and its variations
dia	diagonal format
sky	skyline storage format
bsr	block sparse row format and its variations

The `<operation>` field indicates the type of operation:

mv	matrix-vector product (Level 2)
mm	matrix-matrix product (Level 3)
sv	solving a single triangular system (Level 2)
sm	solving triangular systems with multiple right-hand sides (Level 3)

The field `<mtype>` indicates the matrix type:

<code>ge</code>	sparse representation of a general matrix
<code>sy</code>	sparse representation of the upper or lower triangle of a symmetric matrix
<code>tr</code>	sparse representation of a triangular matrix

Sparse Matrix Storage Formats

The current version of Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following point entry [Duff86] storage formats for sparse matrices:

- *compressed sparse row* format (CSR) and its variations;
- *compressed sparse column* format (CSC);
- *coordinate* format;
- *diagonal* format;
- *skyline* storage format;

and one block entry storage format:

- *block sparse row* format (BSR) and its variations.

For more information see "[Sparse Matrix Storage Formats](#)" in the Appendix A ".

Routines and Supported Operations

This section describes operations supported by the Intel Sparse BLAS Level 2 and Level 3 routines. The following notations are used here:

A is a sparse matrix;
 B and C are dense matrices;
 D is a diagonal scaling matrix;
 x and y are dense vectors;
 α and β are scalars;

$\text{op}(A)$ is one of the possible operations:

$\text{op}(A) = A$;
 $\text{op}(A) = A^T$ - transpose of A ;

$\text{op}(A) = \text{conj}(A')$ - conjugated transpose of A .

$\text{inv}(\text{op}(A))$ denotes the inverse of $\text{op}(A)$.

Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following operations:

- computing the vector product between a sparse matrix and a dense vector:

$$y := \alpha * \text{op}(A) * x + \beta * y$$

- solving a single triangular system:

$$y := \alpha * \text{inv}(\text{op}(A)) * x$$

- computing a product between sparse matrix and dense matrix:

$$C := \alpha * \text{op}(A) * B + \beta * C$$

- solving a sparse triangular system with multiple right-hand sides:

$$C := \alpha * \text{inv}(\text{op}(A)) * B$$

Intel MKL provides an additional set of Sparse BLAS Level 2 routines with *simplified interfaces*. Each of these routines operates on a matrix of the fixed type. The following operations are supported:

- computing the vector product between a sparse matrix and a dense vector (for general and symmetric matrices):

$$y := \text{op}(A) * x$$

- solving a single triangular system (for triangular matrices):

$$y := \text{inv}(\text{op}(A)) * x$$

Matrix type is indicated by the field `<mtype>` in the routine name (see section [Naming Conventions in Sparse BLAS Level 2 and Level 3](#)).

NOTE. The routines with simplified interfaces support only four sparse matrix storage formats, specifically:

CSR format in the 3-array variation accepted in the direct sparse solvers and in the CXML;

diagonal format accepted in the CXML;

coordinate format;

BSR format in the 3-array variation.

Note that routines with both typical (conventional) and simplified interfaces use the same computational kernels that work with certain internal data structures.

Complete list of all routines is given in the [Table 2-9](#) .

Interface Consideration

One-Based and Zero-Based Indexing

The Intel MKL Sparse BLAS Leve2 and Level 3 routines support one-based and zero-based indexing of data arrays.

Routines with typical interfaces support zero-based indexing for the following sparse data storage formats: CSR, CSC, BSR, and COO. Routines with simplified interfaces support zero based indexing for the following sparse data storage formats: CSR, BSR, and COO. See the complete list of [Sparse BLAS Level 2 and Level 3 Routines](#) .

The one-based indexing uses the convention of starting array indices at 1. The zero-based indexing uses the convention of starting array indices at 0. For example, indices of the 5-element array *x* can be presented in case of one-based indexing as follows:

```
Element index:      1      2      3      4      5
```

```
Element value:      1.0   5.0   7.0   8.0   9.0
```

and in case of zero-based indexing as follows:

```
Element index:      0      1      2      3      4
```

```
Element value:      1.0   5.0   7.0   8.0   9.0
```

The detailed descriptions of the one-based and zero-based variants of the sparse data storage formats are given in the “[Sparse Matrix Storage Formats](#)” in Appendix A

Most parameters of the routines are identical for both one-based and zero-based indexing, but some of them have certain differences. The following table lists all these differences.

Parameter	One-based Indexing	Zero-based Indexing
<i>val</i>	Array containing non-zero elements of the matrix <i>A</i> , its length is <i>pntre</i> (<i>m</i>) – <i>pntrb</i> (1).	Array containing non-zero elements of the matrix <i>A</i> , its length is <i>pntre</i> (<i>m</i> –1) – <i>pntrb</i> (0).

<i>pntrb</i>	Array of length m . This array contains row indices, such that $pntrb(I) - pntrb(1)+1$ is the first index of row I in the arrays <i>val</i> and <i>indx</i>	Array of length m . This array contains row indices, such that $pntrb(I) - pntrb(0)$ is the first index of row I in the arrays <i>val</i> and <i>indx</i> .
<i>pntre</i>	Array of length m . This array contains row indices, such that $pntre(I) - pntrb(1)$ is the last index of row I in the arrays <i>val</i> and <i>indx</i> .	Array of length m . This array contains row indices, such that $pntre(I) - pntrb(0)-1$ is the last index of row I in the arrays <i>val</i> and <i>indx</i> .
<i>ia</i>	Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one.	Array of length $m+1$, containing indices of elements in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m)$ is equal to the number of non-zeros.
<i>ldb</i>	Specifies the first dimension of <i>b</i> as declared in the calling (sub)program.	Specifies the second dimension of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.	Specifies the second dimension of <i>c</i> as declared in the calling (sub)program.

Difference Between Fortran and C Interfaces

Intel MKL provides both Fortran and C interfaces to all Sparse BLAS Leve2 and Level 3 routines. Parameter descriptions are common for both interfaces with the exception of data types that refer to the FORTRAN 77 standard types. Correspondence between data types specific to the Fortran and C interfaces are given below:

Fortran	C
REAL*4	float
REAL*8	double
INTEGER*4	int
INTEGER*8	long long int
CHARACTER	char

For routines with C interfaces all parameters (including scalars) must be passed by references. Another difference is how two-dimensional arrays are represented. In Fortran the column-major order is used, and in C - row-major order. This changes the meaning of the parameters *ldb* and *ldc* (see the table above).

Differences Between Intel MKL and NIST* Interfaces

The Intel MKL Sparse BLAS Level 3 routines have the following conventional interfaces:

`mkl_xyyyymm(transa, m, n, k, alpha, matdescra, arg(A), b, ldb, beta, c, ldc)`, for matrix-matrix product;

`mkl_xyyysm(transa, m, n, alpha, matdescra, arg(A), b, ldb, c, ldc)`, for triangular solvers with multiple right-hand sides.

Here *x* denotes data type, and *yyy* - sparse matrix data structure (storage format).

The analogous NIST* Sparse BLAS (NSB) library routines have the following interfaces:

`xyyyymm(transa, m, n, k, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for matrix-matrix product;

`xyyyysm(transa, m, n, unitd, dv, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for triangular solvers with multiple right-hand sides.

Some similar arguments are used in both libraries. The argument *transa* indicates what operation is performed and is slightly different in the NSB library (see [Table 2-5](#)). The arguments *m* and *k* are the number of rows and column in the matrix *A*, respectively, *n* is the number of columns in the matrix *C*. The arguments *alpha* and *beta* are scalar *alpha* and *beta* respectively (*beta* is not used in the Intel MKL triangular solvers.) The arguments *b* and *c* are rectangular arrays with the first dimension *ldb* and *ldc*, respectively. *arg(A)* denotes the list of arguments that describe the sparse representation of *A*.

Table 2-5 Parameter *transa*

	MKL interface	NSB interface	Operation
data type	CHARACTER*1	INTEGER	
value	N or n	0	$op(A) = A$
	T or t	1	$op(A) = A'$
	C or c	2	$op(A) = A'$

Parameter matdescra

The parameter *matdescra* describes the relevant characteristic of the matrix *A*. This manual describes *matdescra* as an array of six elements in line with the NIST* implementation. However, only the first four elements of the array are used in the current versions of the Intel MKL Sparse BLAS routines. Elements *matdescra* (5) and *matdescra*(6) are reserved for future use. Note that whether *matdescra* is described in the user's program as an array of length 6 or 4 is of no importance because the array is declared as a pointer in the Intel MKL routines. To learn more about declaration of the *matdescra* array see Sparse BLAS examples located in the following subdirectory of the Intel MKL installation directory: *examples/spblas/*. The table below list elements of the parameter *matdescra*, their values and meanings. The parameter *matdescra* corresponds to the argument *descra* from NSB library.

Table 2-6 Possible Values of the Parameter *matdescra* (*descra*)

MKL interface		NSB interfaceMatrix characteristics		
	one-based indexing	zero-based indexing		
data type	CHARACTER	Char	INTEGER	
1st element	<i>matdescra</i> (1)	<i>matdescra</i> (0)	<i>descra</i> (1)	matrix structure
value	G	G	0	general
	S	S	1	symmetric ($A = A'$)
	H	H	2	Hermitian ($A = \text{conjg}(A')$)
	T	T	3	triangular
	A	A	4	skew(anti)-symmetric ($A = -A'$)
	D	D	5	diagonal
2nd element	<i>matdescra</i> (2)	<i>matdescra</i> (1)	<i>descra</i> (2)	upper/lower triangular indicator
value	L	L	1	lower
	U	U	2	upper
3rd element	<i>matdescra</i> (3)	<i>matdescra</i> (2)	<i>descra</i> (3)	main diagonal type

	MKL interface		NSB interface	Matrix characteristics
value	N	N	0	non-unit
	U	U	1	unit
4th element	<i>matdescra</i> (4) <i>matdescra</i> (3)			type of indexing
value	F			one-based indexing
		C		zero-based indexing

In some cases possible element values of the parameter *matdescra* depend on the values of other elements. The [Table 2-7 "Possible Combinations of Element Values of the Parameter *matdescra*"](#) lists all possible combinations of element values for both multiplication routines and triangular solvers.

Table 2-7 Possible Combinations of Element Values of the Parameter *matdescra*

Routines	<i>matdescra</i> (1)	<i>matdescra</i> (2)	<i>matdescra</i> (3)	<i>matdescra</i> (4)
Multiplication Routines	G	ignored	ignored	F (default) or C
	S or H	L (default)	N (default)	F (default) or C
	S or H	L (default)	U	F (default) or C
	S or H	U	N (default)	F (default) or C
	S or H	U	U	F (default) or C
	A	L (default)	ignored	F (default) or C
	A	U	ignored	F (default) or C
Multiplication Routines and Triangular Solvers	T	L	U	F (default) or C
	T	L	N	F (default) or C
	T	U	U	F (default) or C
	T	U	N	F (default) or C
	D	ignored	N (default)	F (default) or C
	D	ignored	U	F (default) or C

For a matrix in the skyline format with main diagonal declared to be unit, diagonal elements must be stored in the sparse representation even if they are zero. In all other formats diagonal elements can be stored (if needed) in the sparse representation if they are not zero.

Operations with Partial Matrices

One of the distinctive feature of the Intel MKL Sparse BLAS routines is a possibility to perform operations only on partial matrices composed of certain parts (triangles and main diagonal) of the input sparse matrix. It can be done by setting properly first three elements of the parameter *matdescra*.

An arbitrary sparse matrix A can be decomposed as

$$A = L + D + U$$

where L is the strict lower triangle of A , U is the strict upper triangle of A , D is the main diagonal.

Table 2-8 shows correspondence between the output matrices and values of the parameter *matdescra* for the sparse matrix A for multiplication routines.

Table 2-8 Output Matrices for Multiplication Routines

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix
G	ignored	ignored	$\alpha * \text{op}(A) * x + \beta * y$ $\alpha * \text{op}(A) * B + \beta * C$
S or H	L	N	$\alpha * \text{op}(L+D+L') * x + \beta * y$ $\alpha * \text{op}(L+D+L') * B + \beta * C$
S or H	L	U	$\alpha * \text{op}(L+I+L') * x + \beta * y$ $\alpha * \text{op}(L+I+L') * B + \beta * C$
S or H	U	N	$\alpha * \text{op}(U'+D+U) * x + \beta * y$ $\alpha * \text{op}(U'+D+U) * B + \beta * C$
S or H	U	U	$\alpha * \text{op}(U'+I+U) * x + \beta * y$ $\alpha * \text{op}(U'+I+U) * B + \beta * C$
T	L	U	$\alpha * \text{op}(L+I) * x + \beta * y$ $\alpha * \text{op}(L+I) * B + \beta * C$

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix
T	L	N	$\alpha * \text{op}(L+D) * x + \beta * y$ $\alpha * \text{op}(L+D) * B + \beta * C$
T	U	U	$\alpha * \text{op}(U+I) * x + \beta * y$ $\alpha * \text{op}(U+I) * B + \beta * C$
T	U	N	$\alpha * \text{op}(U+D) * x + \beta * y$ $\alpha * \text{op}(U+D) * B + \beta * C$
A	L	ignored	$\alpha * \text{op}(L-L') * x + \beta * y$ $\alpha * \text{op}(L-L') * B + \beta * C$
A	U	ignored	$\alpha * \text{op}(U-U') * x + \beta * y$ $\alpha * \text{op}(U-U') * B + \beta * C$
D	ignored	N	$\alpha * D * x + \beta * y$ $\alpha * D * B + \beta * C$
D	ignored	U	$\alpha * x + \beta * y$ $\alpha * B + \beta * C$

Table 2-9 shows correspondence between the output matrices and values of the parameter *matdescra* for the sparse matrix *A* for triangular solvers.

Table 2-9 Output Matrices for Triangular Solvers

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix
T	L	N	$\alpha * \text{inv}(\text{op}(L+L)) * x$ $\alpha * \text{inv}(\text{op}(L+L)) * B$
T	L	U	$\alpha * \text{inv}(\text{op}(L+L)) * x$ $\alpha * \text{inv}(\text{op}(L+L)) * B$
T	U	N	$\alpha * \text{inv}(\text{op}(U+U)) * x$ $\alpha * \text{inv}(\text{op}(U+U)) * B$
T	U	U	$\alpha * \text{inv}(\text{op}(U+U)) * x$

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix

D	ignored	N	$\alpha * \text{inv}(D) * x$
			$\alpha * \text{inv}(D) * B$
D	ignored	U	$\alpha * x$
			$\alpha * B$

Sparse BLAS Level 2 and Level 3 Routines.

Table 2-9 lists the sparse BLAS Level 2 and Level 3 routines described in more detail later in this section.

Table 2-9 Sparse BLAS Level 2 and Level 3 Routines

Routine/Function	Description

Simplified interface, one-based indexing

<code>mkl_?csrghemv</code>	Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation)
<code>mkl_dbsrghemv</code>	Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation).
<code>mkl_dcoogemv</code>	Computes matrix - vector product of a sparse general matrix in the coordinate format.
<code>mkl_ddiagemv</code>	Computes matrix - vector product of a sparse general matrix in the diagonal format.
<code>mkl_dcsrcsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation)
<code>mkl_dbsrcsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation).
<code>mkl_dcoosymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format.

Routine/Function	Description
<code>mkl_ddiasymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the diagonal format.
<code>mkl_dcsrtrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation).
<code>mkl_dbsrtrsv</code>	Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation).
<code>mkl_dcootrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the coordinate format.
<code>mkl_ddiattrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the diagonal format.

Simplified interface, zero-based indexing

<code>mkl_cspblas_dcsrgemv</code>	Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_dbsrgemv</code>	Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_dcoogemv</code>	Computes matrix - vector product of a sparse general matrix in the coordinate format with zero-based indexing.
<code>mkl_cspblas_dcsrsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_dbsrsymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_dcoosymv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format with zero-based indexing.
<code>mkl_cspblas_dcsrtrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_dbsrtrsv</code>	Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation) with zero-based indexing.

Routine/Function	Description
<code>mk1_cspblas_dcootrsv</code>	Triangular solver with simplified interface for a sparse matrix in the coordinate format with zero-based indexing.

Typical (conventional) interface, one-based and zero-based indexing

<code>mk1_dcsrcmv</code>	Computes matrix - vector product of a sparse matrix in the CSR format.
<code>mk1_dbsrcmv</code>	Computes matrix - vector product of a sparse matrix in the BSR format.
<code>mk1_dcscmv</code>	Computes matrix - vector product for a sparse matrix in the CSC format.
<code>mk1_dcoomv</code>	Computes matrix - vector product for a sparse matrix in the coordinate format.
<code>mk1_dcsrcsv</code>	Solves a system of linear equations for a sparse matrix in the CSR format.
<code>mk1_dbsrcsv</code>	Solves a system of linear equations for a sparse matrix in the BSR format.
<code>mk1_dcscsv</code>	Solves a system of linear equations for a sparse matrix in the CSC format.
<code>mk1_dcoosv</code>	Solves a system of linear equations for a sparse matrix in the coordinate format.
<code>mk1_dcsrcmm</code>	Computes matrix - matrix product of a sparse matrix in the CSR format
<code>mk1_dbsrcmm</code>	Computes matrix - matrix product of a sparse matrix in the BSR format.
<code>mk1_dcscmm</code>	Computes matrix - matrix product of a sparse matrix in the CSC format
<code>mk1_dcoomm</code>	Computes matrix - matrix product of a sparse matrix in the coordinate format.

Routine/Function	Description
<code>mk1_dcsrsm</code>	Solves a system of linear matrix equations for a sparse matrix in the CSR format.
<code>mk1_dbsrsm</code>	Solves a system of linear matrix equations for a sparse matrix in the BSR format.
<code>mk1_dcscsm</code>	Solves a system of linear matrix equations for a sparse matrix in the CSC format.
<code>mk1_dcoosm</code>	Solves a system of linear matrix equations for a sparse matrix in the coordinate format.

Typical (conventional) interface, one-based indexing

<code>mk1_ddiamv</code>	Computes matrix - vector product of a sparse matrix in the diagonal format.
<code>mk1_dskymv</code>	Computes matrix - vector product for a sparse matrix in the skyline storage format.
<code>mk1_ddiasv</code>	Solves a system of linear equations for a sparse matrix in the diagonal format.
<code>mk1_dskysv</code>	Solves a system of linear equations for a sparse matrix in the skyline format.
<code>mk1_ddiamm</code>	Computes matrix - matrix product of a sparse matrix in the diagonal format.
<code>mk1_dskymm</code>	Computes matrix - matrix product of a sparse matrix in the skyline storage format.
<code>mk1_ddiasm</code>	Solves a system of linear matrix equations for a sparse matrix in the diagonal format.
<code>mk1_dskysm</code>	Solves a system of linear matrix equations for a sparse matrix in the skyline storage format.

mkl_?csrgev

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrgev(transa, m, a, ia, ja, x, y)
call mkl_dcsrgev(transa, m, a, ia, ja, x, y)
```

C:

```
mkl_scsrgev(&transa, &m, a, ia, ja, x, y);
mkl_dcsrgev(&transa, &m, a, ia, ja, x, y);
```

Description

The `mkl_?csrgev` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the CSR format (3-array variation), A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the operation.

	If <i>transa</i> = 'N' or 'n', then as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A' * x$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>a</i>	REAL*4 for mkl_scsrgev. REAL*8 for mkl_dcscrgev. Array containing non-zero elements of the matrix <i>A</i>. Its length is equal to the number of non-zero elements in the matrix <i>A</i>. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i>, such that <i>ia</i>(<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i>. The value of the last element <i>ia</i>($m + 1$) is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to the length of the array <i>a</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>x</i>	REAL*4 for mkl_scsrgev. REAL*8 for mkl_dcscrgev. Array, DIMENSION is <i>m</i>. On entry, the array <i>x</i> must contain the vector <i>x</i>.

Output Parameters

<i>y</i>	REAL*4 for mkl_scsrgev. REAL*8 for mkl_dcscrgev. Array, DIMENSION at least <i>m</i>. On exit, the array <i>y</i> must contain the vector <i>y</i>.

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_scsrgemv(transa, m, a, ia, ja, x, y)
    CHARACTER*1  transa
    INTEGER      m
    INTEGER      ia(*), ja(*)
    REAL*4       a(*), x(*), y(*)
SUBROUTINE mkl_dcsrgemv(transa, m, a, ia, ja, x, y)
    CHARACTER*1  transa
    INTEGER      m
    INTEGER      ia(*), ja(*)
    REAL*8       a(*), x(*), y(*)

```

C:

```

void mkl_scsrgemv(char *transa, int *m, float *a,
    int *ia, int *ja, float *x, float *y);
void mkl_dcsrgemv(char *transa, int *m, double *a,
    int *ia, int *ja, double *x, double *y);

```

mkl_dbsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_dbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
```

Description

The `mkl_dbsrgemv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation), A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A' * x,$
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>a</i>	REAL*8. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i> . Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The

value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to *rowIndex* array description in for more details.

ja REAL*8. Array containing the column indices for each non-zero block in the matrix *A*.
Its length is equal to the number of non-zero blocks of the matrix *A*. Refer to *columns* array description in [BSR Format](#) for more details.

x REAL*8.
Array, DIMENSION ($m*lb$).
On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL*8.
Array, DIMENSION at least ($m*lb$).
On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
  CHARACTER*1  transa
  INTEGER      m, lb
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_dbsrgemv(char *transa, int *m, int *lb, double *a,
int *ia, int *ja, double *x, double *y);
```

mkl_dcoogemv

Computes matrix - vector product of a sparse general matrix stored in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_dcoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
```

Description

The `mkl_dcoogemv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A' * x,$

<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>val</i>	REAL*8. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . One entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
  CHARACTER*1  transa
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8      val(*), x(*), y(*)

```

C:

```
void mkl_dcoogemv(char *transa, int *m, double *val, int *rowind,  
int *colind, int *nnz, double *x, double *y);
```

mkl_ddiagemv

Computes matrix - vector product of a sparse general matrix stored in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_ddiagemv(transa, m, val, lval, idiag, ndiag, x, y)
```

C:

```
mkl_ddiagemv(&transa, &m, val, &lval, idiag, &ndiag, x, y);
```

Description

The `mkl_ddiagemv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the diagonal storage format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the operation.

	If <i>transa</i> = 'N' or 'n', then $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_ddiagemv(transa, m, val, lval, idiag, ndiag, x, y)
  CHARACTER*1  transa
  INTEGER      m, lval, ndiag
  INTEGER      idiag(*)
  REAL*8       val(lval,*), x(*), y(*)

```

C:

```
void mkl_ddiagemv(char *transa, int *m, double *val, int *lval,  
    int *idiag, int *ndiag, double *x, double *y);
```

mkl_dcsrsvmv

Computes matrix - vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_dcsrsvmv(uplo, m, a, ia, ja, x, y)
```

C:

```
mkl_dcsrsvmv(&uplo, &m, a, ia, ja, x, y);
```

Description

The `mkl_dcsrsvmv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation), A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>a</i>	REAL*8. Array containing non-zero elements of the matrix <i>A</i>. Its length is equal to the number of non-zero elements in the matrix <i>A</i>. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i>, such that <i>ia</i>(<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i>. The value of the last element <i>ia</i>($m + 1$) is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to the length of the array <i>a</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i>. On entry, the array <i>x</i> must contain the vector <i>x</i>.

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i>. On exit, the array <i>y</i> must contain the vector <i>y</i>.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrsymv(uplo, m, a, ia, ja, x, y)

  CHARACTER*1  uplo
  INTEGER      m
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_dcsrsymv(char *uplo, int *m, double *a,
  int *ia, int *ja, double *x, double *y);
```

mkl_dbsrsymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_dbsrsymv(&uplo, &m, &lb, a, ia, ja, x, y);
```

Description

The `mkl_dbsrsymv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation), A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL*8. Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that $ia(i)$ is the index in the array <i>a</i> of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks of the matrix A . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL*8.

Array, DIMENSION $(m*lb)$.
On entry, the array x must contain the vector x .

Output Parameters

y REAL*8.
Array, DIMENSION at least $(m*lb)$.
On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER      m, lb
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_dbsrsymv(char *uplo, int *m, int *lb,
  double *a, int *ia, int *ja, double *x, double *y);
```

mkl_dcoosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_dcoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
```

Description

The `mk1_dcoosymv` routine performs a matrix-vector operation defined as

$$y := A * x$$

or

$$y := A' * x,$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of rows of the matrix A.
<i>val</i>	REAL*8. Array of length <i>nnz</i>, contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix A. Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
  CHARACTER*1  uplo
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8       val(*), x(*), y(*)

```

C:

```

void mkl_dcoosymv(char *uplo, int *m, double *val, int *rowind,
  int *colind, int *nnz, double *x, double *y);

```

mkl_ddiasymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_ddiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)
```

C:

```
mkl_ddiasymv(&uplo, &m, val, &lval, iddiag, &ndiag, x, y);
```

Description

The `mkl_ddiasymv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used.

	If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , <i>lval</i> ≥ <i>m</i> . Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_ddiasymv(uplo, m, val, lval, idiag, ndiag, x, y)
  CHARACTER*1  uplo
  INTEGER      m, lval, ndiag
  INTEGER      idiag(*)
  REAL*8       val(lval,*), x(*), y(*)

```

C:

```
void mkl_ddiasymv(char *uplo, int *m, double *val, int *lval,  
    int *idiag, int *ndiag, double *x, double *y);
```

mkl_dcsrtrsv

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_dcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
```

C:

```
mkl_dcsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
```

Description

The `mkl_dcsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3 array variation):

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is a unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>a</i>	REAL*8. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> ($m + 1$) is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.

NOTE. Column indices must be sorted in increasing order for each row.

x REAL*8.
 Array, DIMENSION is *m*.
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL*8.
 Array, DIMENSION at least *m*.
 Contains the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
  CHARACTER*1 uplo, transa, diag
  INTEGER      m
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_dcsrtrsv(char *uplo, char *transa, char *diag, int *m,
  double *a, int *ia, int *ja, double *x, double *y);
```

mkl_dbsrtrsv

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_dbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_dbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
```

Description

The `mkl_dbsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) :

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A' * x$.
<i>diag</i>	CHARACTER*1. Specifies whether A is a unit triangular matrix. If <i>diag</i> = 'U' or 'u', then A is a unit triangular. If <i>diag</i> = 'N' or 'n', then A is not a unit triangular.
<i>m</i>	INTEGER. Number of block rows of the matrix A.

<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>a</i>	REAL*8. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i> . Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that <i>ia(i)</i> is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia(m + 1)</i> is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION $(m*lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least $(m*lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
    CHARACTER*1 uplo, transa, diag
    INTEGER      m, lb
    INTEGER      ia(*), ja(*)
    REAL*8       a(*), x(*), y(*)

```

C:

```
void mkl_dbsrtrsv(char *uplo, char *transa, char *diag, int *m,  
    int *lb, double *a, int *ia, int *ja, double *x, double *y);
```

mkl_dcootrsv

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_dcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_dcootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz, x, y);
```

Description

The `mkl_dcootrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format:

$$A * y = x$$

or

$$A' * y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <i>A</i> is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>val</i>	REAL*8. Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>. Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i>. Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i>. On entry, the array <i>x</i> must contain the vector <i>x</i>.

Output Parameters

y REAL*8.
 Array, DIMENSION at least *m*.
 Contains the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
  CHARACTER*1  uplo, transa, diag
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8       val(*), x(*), y(*)
```

C:

```
void mkl_dcootrsv(char *uplo, char *transa, char *diag, int *m,
  double *alpha, char *matdescra, double *val, int *rowind,
  int *colind, int *nnz, double *x, double *y);
```

mkl_ddiattrsv

Triangular solvers with simplified interface for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_ddiattrsv(uplo, transa, diag, m, val, lval, idiag, ndiag, x, y)
```

C:

```
mkl_ddiattrsv(&uplo, &transa, &diag, &m, val, &lval, idiag, &ndiag, x, y);
```

Description

The `mkl_ddiattrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A.

<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> .

NOTE. All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . Contains the vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_ddiatsrv(uplo, transa, diag, m, val, lval, idiag, ndiag, x, y)
  CHARACTER*1  uplo, transa, diag
  INTEGER      m, lval, ndiag
  INTEGER      idiag(*)
  REAL*8       val(lval,*), x(*), y(*)
```

C:

```
void mkl_ddiatsrv(char *uplo, char *transa, char *diag, int *m, double
  *val, int *lval, int *idiag, int *ndiag, double *x, double *y);
```

mkl_cspblas_dcsrgemv

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dcsrgemv(transa, m, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_dcsrgemv(&transa, &m, a, ia, ja, x, y);
```

Description

The `mkl_cspblas_dcsrgemv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the CSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	REAL*8. Array containing non-zero elements of the matrix A. Its length is equal to the number of non-zero elements in the matrix A. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i>, such that <i>ia</i>(<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i>. The value of the last element <i>ia</i>(<i>m</i>) is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero element of the matrix A. Its length is equal to the length of the array <i>a</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i>. One entry, the array <i>x</i> must contain the vector <i>x</i>.

Output Parameters

y REAL*8.
 Array, DIMENSION at least *m*.
 On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dcsrgemv(transa, m, a, ia, ja, x, y)
  CHARACTER*1 transa
  INTEGER      m
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dcsrgemv(char *transa, int *m, double *a,
int *ia, int *ja, double *x, double *y);
```

mkl_cspblas_dbsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_dbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
```

Description

The `mkl_cspblas_dbsrgemv` routine performs a matrix-vector operation defined as

$y := A \cdot x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A' * x,$
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL*8. Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero block in the matrix A .

Its length is equal to the number of non-zero blocks of the matrix *A*. Refer to *columns* array description in [BSR Format](#) for more details.

x REAL*8.
 Array, DIMENSION (*m*lb*).
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL*8.
 Array, DIMENSION at least (*m*lb*).
 On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
    CHARACTER*1  transa
    INTEGER      m, lb
    INTEGER      ia(*), ja(*)
    REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dbsrgemv(char *transa, int *m, int *lb,
    double *a, int *ia, int *ja, double *x, double *y);
```

mkl_cspblas_dcoogemv

Computes matrix - vector product of a sparse general matrix stored in the coordinate format with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_cspblas_dcoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
```

Description

The `mkl_cspblas_dcoogemv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A' * x,$
<i>m</i>	INTEGER. Number of rows of the matrix A.
<i>val</i>	REAL*8. Array of length <i>nnz</i>, contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix A. Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
  CHARACTER*1  transa
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8       val(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dcoogemv(char *transa, int *m, double *val, int *rowind,
  int *colind, int *nnz, double *x, double *y);
```

mkl_cspblas_dcsrsvmv

Computes matrix - vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dcsrsvmv(uplo, m, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_dcsrsvmv(&uplo, &m, a, ia, ja, x, y);
```

Description

The `mkl_cspblas_dcsrsvmv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used.

If `uplo = 'U'` or `'u'`, then the upper triangle of the matrix `A` is used.

If `uplo = 'L'` or `'l'`, then the low triangle of the matrix `A` is used.

<code>m</code>	INTEGER. Number of rows of the matrix <code>A</code> .
<code>a</code>	REAL*8. Array containing non-zero elements of the matrix <code>A</code> . Its length is equal to the number of non-zero elements in the matrix <code>A</code> . Refer to <code>values</code> array description in Sparse Matrix Storage Formats for more details.
<code>ia</code>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <code>a</code> , such that <code>ia(i)</code> is the index in the array <code>a</code> of the first non-zero element from the row <code>i</code> . The value of the last element <code>ia(m + 1)</code> is equal to the number of non-zeros. Refer to <code>rowIndex</code> array description in Sparse Matrix Storage Formats for more details.
<code>ja</code>	REAL*8. Array containing the column indices for each non-zero element of the matrix <code>A</code> . Its length is equal to the length of the array <code>a</code> . Refer to <code>columns</code> array description in Sparse Matrix Storage Formats for more details.
<code>x</code>	REAL*8. Array, DIMENSION is <code>m</code> . On entry, the array <code>x</code> must contain the vector <code>x</code> .

Output Parameters

<code>y</code>	REAL*8. Array, DIMENSION at least <code>m</code> . On exit, the array <code>y</code> must contain the vector <code>y</code> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dcsrsymv(uplo, m, a, ia, ja, x, y)
    CHARACTER*1 uplo
    INTEGER      m
    INTEGER      ia(*), ja(*)
    REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dcsrsymv(char *uplo, int *m, double *a,
    int *ia, int *ja, double *x, double *y);
```

mkl_cspblas_dbsrsymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the BSR format (3-arrays variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_dbsrsymv(&uplo, &m, &lb, a, ia, ja, x, y);
```

Description

The `mkl_cspblas_dbsrsymv` routine performs a matrix-vector operation defined as

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL*8. Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that <i>ia</i> (<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> ($m + 1$) is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero block in the matrix A . Its length is equal to the number of non-zero blocks of the matrix A . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL*8.

Array, DIMENSION $(m*lb)$.
On entry, the array x must contain the vector x .

Output Parameters

y REAL*8.
Array, DIMENSION at least $(m*lb)$.
On exit, the array y must contain the vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
  CHARACTER*1 uplo
  INTEGER      m, lb
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dbsrsymv(char *uplo, int *m, int *lb,
double *a, int *ia, int *ja, double *x, double *y);
```

mkl_cspblas_dcoosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with zero-based indexing .

Syntax

Fortran:

```
call mkl_cspblas_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_cspblas_dcoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
```

Description

The `mk1_cspblas_dcoosymv` routine performs a matrix-vector operation defined as

$$y := A * x$$

or

$$y := A' * x,$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL*8. Array of length <i>nnz</i>, contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix A. Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
  CHARACTER*1  uplo
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8       val(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dcoosymv(char *uplo, int *m, double *val, int *rowind,
  int *colind, int *nnz, double *x, double *y);
```

mkl_cspblas_dcsrtrsv

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_dcsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
```

Description

The `mkl_cspblas_dcsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3-array variation) with zero-based indexing:

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

`uplo` CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used.

	If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether matrix <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>a</i>	REAL*8. Array containing non-zero elements of the matrix <i>A</i>. Its length is equal to the number of non-zero elements in the matrix <i>A</i>. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length <i>m</i>+1, containing indices of elements in the array <i>a</i>, such that <i>ia</i>(<i>i</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i>. The value of the last element <i>ia</i>(<i>m</i>) is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to the length of the array <i>a</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
	 NOTE. Column indices must be sorted in increasing order for each row.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i>. On entry, the array <i>x</i> must contain the vector <i>x</i>.

Output Parameters

y REAL*8.
Array, DIMENSION at least *m*.
Contains the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
  CHARACTER*1 uplo, transa, diag
  INTEGER      m
  INTEGER      ia(*), ja(*)
  REAL*8       a(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dcsrtrsv(char *uplo, char *transa, char *diag, int *m,
double *a, int *ia, int *ja, double *x, double *y);
```

mkl_cspblas_dbsrtrsv

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_dbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_dbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
```

Description

The `mk1_cspblas_dbsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing:

$y := A * x$

or

$y := A' * x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A' * x$.
<i>diag</i>	CHARACTER*1. Specifies whether matrix A is unit triangular or not. If <i>diag</i> = 'U' or 'u', A is unit triangular. If <i>diag</i> = 'N' or 'n', A is not unit triangular.

<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>a</i>	REAL*8. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i> . Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array <i>a</i> , such that <i>ia(I)</i> is the index in the array <i>a</i> of the first non-zero element from the row <i>I</i> . The value of the last element <i>ia(m + 1)</i> is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	REAL*8. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION $(m*lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL*8. Array, DIMENSION at least $(m*lb)$. On exit, the array <i>y</i> must contain the vector <i>y</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_cspblas_dbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
    CHARACTER*1 uplo, transa, diag
    INTEGER      m, lb
    INTEGER      ia(*), ja(*)
    REAL*8       a(*), x(*), y(*)

```

C:

```
void mkl_cspblas_dbsrtrsv(char *uplo, char *transa, char *diag, int *m,  
int *lb, double *a, int *ia, int *ja, double *x, double *y);
```

mkl_cspblas_dcootrsv

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with zero-based indexing .

Syntax

Fortran:

```
call mkl_cspblas_dcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz,  
x, y)
```

C:

```
mkl_cspblas_dcootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz,  
x, y);
```

Description

The `mkl_cspblas_dcootrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format with zero-based indexing:

$$A * y = x$$

or

$$A' * y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix <i>A</i> is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix <i>A</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix <i>A</i> is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>val</i>	REAL*8. Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>. Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i>. Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION is <i>m</i>. On entry, the array <i>x</i> must contain the vector <i>x</i>.

Output Parameters

y REAL*8.
 Array, DIMENSION at least *m*.
 Contains the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_dcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
  CHARACTER*1  uplo, transa, diag
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8       val(*), x(*), y(*)
```

C:

```
void mkl_cspblas_dcootrsv(char *uplo, char *transa, char *diag, int *m,
  double *alpha, char *matdescra, double *val, int *rowind,
  int *colind, int *nnz, double *x, double *y);
```

mkl_dcsrsv

Computes matrix - vector product of a sparse matrix stored in the CSR format.

Syntax

Fortran:

```
call mkl_dcsrsv(transa, m, k, alpha, matdescra, val, indx, pntreb, pntre, x,
  beta, y)
```

C:

```
mkl_dcsrsv(&transa, &m, &k, &alpha, matdescra, val, indx, pntreb, pntre, x,
  &beta, y);
```

Description

The `mkl_dcsrsv` routine performs a matrix-vector operation defined as

$$y := \alpha A x + \beta y$$

or

$$y := \alpha A' x + \beta y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix in the CSR format, A' is the transpose of A .

NOTE. This routine supports CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A' x + \beta y$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix A . For one-based indexing its length is $pntrb(m) - pntrb(1)$. For zero-based indexing its length is $pntrb(m-1) - pntrb(0)$.

	Refer to <i>values</i> array description in CSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i> . For one-based indexing this array contains row indices, such that <i>pntrb(i) - pntrb(1)+1</i> is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i> . For zero-based indexing this array contains row indices, such that <i>pntrb(i) - pntrb(0)</i> is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerb</i> array description in CSR Format for more details.
<i>pntrr</i>	INTEGER. Array of length <i>m</i> . For one-based indexing this array contains row indices, such that <i>pntrr(i) - pntrb(1)</i> is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i> . For zero-based indexing this array contains row indices, such that <i>pntrr(i) - pntrb(0)-1</i> is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerE</i> array description in CSR Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> .

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrsv(transa, m, k, alpha, matdescra, val, indx,
    pntrb, pntre, x, beta, y)
    CHARACTER*1    transa
    CHARACTER       matdescra(*)
    INTEGER         m, k
    INTEGER         indx(*), pntrb(m), pntre(m)
    REAL*8         alpha, beta
    REAL*8         val(*), x(*), y(*)
```

C:

```
void mkl_dcsrsv(char *transa, int *m, int *k, double *alpha, char *matdescra,
    double *val, int *indx, int *pntrb, int *pntre, double *x, double *beta, double *y);
```

mkl_dbsrmv

Computes matrix - vector product of a sparse matrix stored in the BSR format.

Syntax

Fortran:

```
call mkl_dbsrmv(transa, m, k, lb, alpha, matdescra, val, indx, pntrb, pntre,
    x, beta, y)
```

C:

```
mkl_dbsrmv(&transa, &m, &k, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
    x, &beta, y);
```

Description

The `mkl_dbsrmv` routine performs a matrix-vector operation defined as

$$y := \alpha A x + \beta y$$

or

$$y := \alpha A'x + \beta y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k block sparse matrix in the BSR format, A' is the transpose of A .

NOTE. This routine supports BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := \alpha A^*x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := \alpha A'^*x + \beta y$,
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.

<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i>. Refer to <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i>. For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntre</i>	INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerE</i> array description in BSR Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION at least $(k*lb)$ if <i>transa</i> = 'N' or 'n', and at least $(m*lb)$ otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i>.
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>y</i>	REAL*8. Array, DIMENSION at least $(m*lb)$ if <i>transa</i> = 'N' or 'n', and at least $(k*lb)$ otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i>.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dbsrmv(transa, m, k, lb, alpha, matdescra, val, indx,  
  pntrb, pntre, x, beta, y)  
  CHARACTER*1  transa  
  CHARACTER    matdescra(*)  
  INTEGER      m, k, lb  
  INTEGER      indx(*), pntrb(m), pntre(m)  
  REAL*8       alpha, beta  
  REAL*8       val(*), x(*), y(*)
```

C:

```
void mkl_dbsrmv(char *transa, int *m, int *k, int *lb,  
  
double *alpha, char *matdescra, double *val, int *indx,  
  
int *pntrb, int *pntre, double *x, double *beta, double *y);
```

mkl_dcscmv

Computes matrix - vector product for a sparse matrix in the CSC format.

Syntax

Fortran:

```
call mkl_dcscmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,  
beta, y)
```

C:

```
mkl_dcscmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,  
&beta, y);
```

Description

The `mk1_dcscmv` routine performs a matrix-vector operation defined as

$$y := \alpha A x + \beta y$$

or

$$y := \alpha A' x + \beta y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix in compressed sparse column (CSC) format, A' is the transpose of A .

NOTE. This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A' x + \beta y$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix A . For one-based indexing its length is $\text{pntrc}(k) - \text{pntrb}(1)$.

	For zero-based indexing its length is $pntre(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSC Format for more details.
<i>indx</i>	INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>k</i>. For one-based indexing this array contains column indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerb</i> array description in CSC Format for more details.
<i>pntre</i>	INTEGER. Array of length <i>k</i>. For one-based indexing this array contains column indices, such that $pntre(i) - pntrb(1)$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains column indices, such that $pntre(i) - pntrb(1) - 1$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerE</i> array description in CSC Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i>.
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i>.
<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i>.

Output Parameters

y Overwritten by the updated vector y .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcscmv(transa, m, k, alpha, matdescra, val, indx,
  pntrb, pntre, x, beta, y)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, k, ldb, ldc
  INTEGER      indx(*), pntrb(m), pntre(m)
  REAL*8       alpha, beta
  REAL*8       val(*), x(*), y(*)
```

C:

```
void mkl_dcscmv(char *transa, int *m, int *k, double *alpha,
  char *matdescra, double *val, int *indx, int *pntrb,
  int *pntre, double *x, double *beta, double *y);
```

mkl_dcoomv

Computes matrix - vector product for a sparse matrix in the coordinate format.

Syntax

Fortran:

```
call mkl_dcoomv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
  beta, y)
```

C:

```
mkl_dcoomv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,
&beta, y);
```

Description

The `mkl_dcoomv` routine performs a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A' * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix in compressed coordinate format, *A'* is the transpose of *A*.

NOTE. This routine supports coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A' * x + \beta * y$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .

<i>val</i>	REAL*8. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> .

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcoomv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x, beta,
y)

  CHARACTER*1    transa
  CHARACTER      matdescra(*)
  INTEGER        m, k, nnz
  INTEGER        rowind(*), colind(*)
  REAL*8         alpha, beta
  REAL*8         val(*), x(*), y(*)
```

C:

```
void mkl_dcoomv(char *transa, int *m, int *k, double *alpha, char *matdescra,
double *val, int *rowind, int *colind, int *nnz, double *x, double *beta, double *y);
```

mkl_dcsrsv

Solves a system of linear equations for a sparse matrix in the CSR format.

Syntax

Fortran:

```
call mkl_dcsrsv(transa, m, alpha, matdescra, val, indx, pntreb, pntre, x, y)
```

C:

```
mkl_dcsrsv(&transa, &m, &alpha, matdescra, val, indx, pntreb, pntre, x, y);
```

Description

The `mkl_dcsrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSR format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix A . For one-based indexing its length is $\text{pntrc}(m) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrc}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.

NOTE. Column indices must be sorted in increasing order for each row.

pntrb

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row i in the arrays *val* and *indx*.

For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row i in the arrays *val* and *indx*. Refer to *pointerb* array description in [CSR Format](#) for more details.

pntrb

INTEGER. Array of length m .

For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1)$ is the last index of row i in the arrays *val* and *indx*.

For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0) - 1$ is the last index of row i in the arrays *val* and *indx*. Refer to *pointerE* array description in [CSR Format](#) for more details.

x

REAL*8.

Array, DIMENSION at least m .

On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y

REAL*8.

Array, DIMENSION at least m .

On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y

Contains solution vector *x*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrsv(transa, m, alpha, matdescra, val, indx, pntbr, pntre, x, y)

  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m
  INTEGER      indx(*), pntbr(m), pntre(m)
  REAL*8       alpha
  REAL*8       val(*)
  REAL*8       x(*), y(*)
```

C:

```
void mkl_dcsrsv(char *transa, int *m, double *alpha, char *matdescra,
  double *val, int *indx, int *pntbr, int *pntre, double *x, double *y);
```

mkl_dbsrsv

Solves a system of linear equations for a sparse matrix in the BSR format.

Syntax

Fortran:

```
call mkl_dbsrsv(transa, m, lb, alpha, matdescra, val, indx, pntbr, pntre, x,
y)
```

C:

```
mkl_dbsrsv(&transa, &m, &lb, &alpha, matdescra, val, indx, pntbr, pntre, x,
y);
```

Description

The `mkl_dcsrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the BSR format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i> . Refer to the <i>values</i> array description in BSR Format for more details.

<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i>. Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i>. For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntre</i>	INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerE</i> array description in BSR Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION at least $(m*lb)$. On entry, the array <i>x</i> must contain the vector <i>x</i>. The elements are accessed with unit increment.
<i>y</i>	REAL*8. Array, DIMENSION at least $(m*lb)$. On entry, the array <i>y</i> must contain the vector <i>y</i>. The elements are accessed with unit increment.

Output Parameters

<i>y</i>	Contains solution vector <i>x</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dbsrsv(transa, m, lb, alpha, matdescra, val, indx, pntrb, pntre, x, y)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, lb
  INTEGER      indx(*), pntrb(m), pntre(m)
  REAL*8       alpha
  REAL*8       val(*)
  REAL*8       x(*), y(*)
```

C:

```
void mkl_dbsrsv(char *transa, int *m, int *lb, double *alpha, char *matdescra,
  double *val, int *indx, int *pntrb, int *pntre, double *x, double *y);
```

mkl_dcscsv

Solves a system of linear equations for a sparse matrix in the CSC format.

Syntax

Fortran:

```
call mkl_dcscsv(transa, m, alpha, matdescra, val, indx, pntrb, pntre, x, y)
```

C:

```
mkl_dcscsv(&transa, &m, &alpha, matdescra, val, indx, pntrb, pntre, x, y);
```

Description

The `mkl_dcscsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSC format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix A . For one-based indexing its length is $\text{pntrc}(m) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrc}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSC Format for more details.
<i>indx</i>	INTEGER. Array containing the row indices for each non-zero element of the matrix A . Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSC Format for more details.

NOTE. Row indices must be sorted in increasing order for each column.

pntrb

INTEGER. Array of length *m*.

For one-based indexing this array contains column indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of column *i* in the arrays *val* and *indx*.

For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column *i* in the arrays *val* and *indx*.

Refer to *pointerb* array description in [CSC Format](#) for more details.

pntrc

INTEGER. Array of length *m*.

For one-based indexing this array contains column indices, such that $pntrc(i) - pntrb(1)$ is the last index of column *i* in the arrays *val* and *indx*.

For zero-based indexing this array contains column indices, such that $pntrc(i) - pntrb(1) - 1$ is the last index of column *i* in the arrays *val* and *indx*.

Refer to *pointerE* array description in [CSC Format](#) for more details.

x

REAL*8.

Array, DIMENSION at least *m*.

On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y

REAL*8.

Array, DIMENSION at least *m*.

On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y

Contains the solution vector *x*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcscsv(transa, m, alpha, matdescra, val, indx, pntbr, pntre, x, y)

  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m
  INTEGER      indx(*), pntbr(m), pntre(m)
  REAL*8       alpha
  REAL*8       val(*)
  REAL*8       x(*), y(*)
```

C:

```
void mkl_dcscsv(char *transa, int *m, double *alpha, char *matdescra,
  double *val, int *indx, int *pntbr, int *pntre, double *x, double *y);
```

mkl_dcoosv

Solves a system of linear equations for a sparse matrix in the coordinate format.

Syntax

Fortran:

```
call mkl_dcoosv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
y)
```

C:

```
mkl_dcoosv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,
y);
```

Description

The `mkl_dcoosv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the coordinate format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A .

	Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . The elements are accessed with unit increment.
<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On entry, the array <i>y</i> must contain the vector <i>y</i> . The elements are accessed with unit increment.

Output Parameters

<i>y</i>	Contains solution vector <i>x</i> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dcoosv(transa, m, alpha, matdescra, val, rowind, colind, nnz, x, y)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, nnz
  INTEGER      rowind(*), colind(*)
  REAL*8       alpha
  REAL*8       val(*)
  REAL*8       x(*), y(*)

```

C:

```
void mkl_dcoosv(char *transa, int *m, double *alpha, char *matdescra,
               double *val, int *rowind, int *colind, int *nnz, double *x, double *y);
```

mkl_dcsrmm

Computes matrix - matrix product of a sparse matrix stored in the CSR format.

Syntax

Fortran:

```
call mkl_dcsrmm(transa, m, n, k, alpha, matdescra, val, indx, pntreb, pntre,
               b, ldb, beta, c, ldc)
```

C:

```
mkl_dcsrmm(&transa, &m, &n, &k, &alpha, matdescra, val, indx, pntreb, pntre,
           b, &ldb, &beta, c, &ldc);
```

Description

The `mkl_dcsrmm` routine performs a matrix-matrix operation defined as

$$C := \alpha A * B + \beta C$$

or

$$C := \alpha A' * B + \beta C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse row (CSR) format, *A'* is the transpose of *A*.

NOTE. This routine supports CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix <i>A</i>. For one-based indexing its length is $pntrb(m) - pntrb(1)$. For zero-based indexing its length is $pntrb(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerb</i> array description in CSR Format for more details.

<i>pntrc</i>	INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that <i>pntrc</i>(<i>i</i>) - <i>pntrb</i>(1) is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains row indices, such that <i>pntrc</i>(<i>i</i>) - <i>pntrb</i>(0) - 1 is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerE</i> array description in CSR Format for more details.
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i>, <i>n</i>) for one-based indexing, and (<i>m</i>, <i>ldb</i>) for zero-based indexing. On entry with <i>transa</i>= 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i>.
<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i>, <i>n</i>) for one-based indexing, and (<i>m</i>, <i>ldc</i>) for zero-based indexing. On entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix (<i>alpha</i>*<i>A</i>*<i>B</i> + <i>beta</i>* <i>C</i>) or (<i>alpha</i>*<i>A</i>'*<i>B</i> + <i>beta</i>*<i>C</i>).

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrmm(transa, m, n, k, alpha, matdescra, val, indx,
    pntrb, pntre, b, ldb, beta, c, ldc)
    CHARACTER*1
    transa
    CHARACTER      matdescra(*)
    INTEGER        m, n, k, ldb, ldc
    INTEGER        indx(*), pntrb(m), pntre(m)
    REAL*8         alpha, beta
    REAL*8         val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dcsrmm(char *transa, int *m, int *n, int *k, double *alpha,
    char *matdescra, double *val, int *indx, int *pntrb, int *pntre,
    double *b, int *ldb, double *beta, double *c, int *ldc,);
```

mkl_dbsrmm

Computes matrix - matrix product of a sparse matrix stored in the BSR format.

Syntax

Fortran:

```
call mkl_dbsrmm(transa, m, n, k, lb, alpha, matdescra, val, indx, pntrb,
    pntre, b, ldb, beta, c, ldc)
```

C:

```
mkl_dbsrmm(&transa, &m, &n, &k, &lb, &alpha, matdescra, val, indx, pntrb,
    pntre, b, &ldb, &beta, c, &ldc);
```

Description

The `mkl_dbsrmm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in block sparse row (BSR) format, *A'* is the transpose of *A*.

NOTE. This routine supports BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * A' * B + \beta * C$,
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .

<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing elements of non-zero blocks of the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i> . Refer to the <i>values</i> array description in BSR Format for more details.
<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i>. For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerE</i> array description in BSR Format for more details.
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i>, <i>n</i>) for one-based indexing, DIMENSION (<i>m</i>, <i>ldb</i>) for zero-based indexing. On entry with <i>transa</i>= 'N' or 'n', the leading <i>n</i>-by-<i>k</i> block part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>m</i>-by-<i>n</i> block part of the array <i>b</i> must contain the matrix <i>B</i>.

<i>ldb</i>	INTEGER. Specifies the first dimension (in blocks) of <i>b</i> as declared in the calling (sub)program.
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i> , <i>n</i>) for one-based indexing, DIMENSION (<i>k</i> , <i>ldc</i>) for zero-based indexing. On entry, the leading <i>m</i> -by- <i>n</i> block part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading <i>n</i> -by- <i>k</i> block part of the array <i>c</i> must contain the matrix <i>C</i> .
<i>ldc</i>	INTEGER. Specifies the first dimension (in blocks) of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix ($\alpha * A * B + \beta * C$) or ($\alpha * A' * B + \beta * C$).

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dbsrmm(transa, m, n, k, lb, alpha, matdescra, val,
    indx, pntreb, pntre, b, ldb, beta, c, ldc)
    CHARACTER*1    transa
    CHARACTER       matdescra(*)
    INTEGER         m, n, k, ld, ldb, ldc
    INTEGER         indx(*), pntreb(m), pntre(m)
    REAL*8          alpha, beta
    REAL*8          val(*), b(ldb,*), c(ldc,*)

```

C:

```

void mkl_dbsrmm(char *transa, int *m, int *n, int *k, int *lb,
    double *alpha, char *matdescra, double *val, int *indx, int *pntreb,
    int *pntre, double *b, int *ldb, double *beta, double *c, int *ldc,);

```

mkl_dcscmm

Computes matrix-matrix product of a sparse matrix stored in the CSC format.

Syntax

Fortran:

```
call mkl_dcscmm(transa, m, n, k, alpha, matdescra, val, indx, pntrb, pntre,
b, ldb, beta, c, ldc)
```

C:

```
mkl_dcscmm(&transa, &m, &n, &k, &alpha, matdescra, val, indx, pntrb, pntre,
b, &ldb, &beta, c, &ldc);
```

Description

The `mkl_dcscmm` routine performs a matrix-matrix operation defined as

$$C := \alpha A * B + \beta C$$

or

$$C := \alpha A' * B + \beta C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse column (CSC) format, *A'* is the transpose of *A*.

NOTE. This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the operation.
If *transa* = 'N' or 'n', then $C := \alpha A * B + \beta C$

	If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6.
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix <i>A</i>. For one-based indexing its length is $pntre(k) - pntrb(1)$. For zero-based indexing its length is $pntre(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSC Format for more details.
<i>indx</i>	INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>k</i>. For one-based indexing this array contains column indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerb</i> array description in CSC Format for more details.
<i>pntre</i>	INTEGER. Array of length <i>k</i>. For one-based indexing this array contains column indices, such that $pntre(i) - pntrb(1)$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>.

For zero-based indexing this array contains column indices, such that $\text{pntrc}(i) - \text{pntrb}(1) - 1$ is the last index of column i in the arrays val and indx .

Refer to *pointerE* array description in [CSC Format](#) for more details.

b	REAL*8. Array, DIMENSION(ldb, n) for one-based indexing, and (m, ldb) for zero-based indexing. On entry with $\text{transa} = 'N'$ or $'n'$, the leading k-by-n part of the array b must contain the matrix B, otherwise the leading m-by-n part of the array b must contain the matrix B.
ldb	INTEGER. Specifies the first dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.
β	REAL*8. Specifies the scalar β.
c	REAL*8. Array, DIMENSION(ldc, n) for one-based indexing, and (m, ldc) for zero-based indexing. On entry, the leading m-by-n part of the array c must contain the matrix C, otherwise the leading k-by-n part of the array c must contain the matrix C.
ldc	INTEGER. Specifies the first dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c	Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A' * B + \beta * C)$.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcscmm(transa, m, n, k, alpha, matdescra, val, indx,
    pntrb, pntre, b, ldb, beta, c, ldc)
    CHARACTER*1    transa
    CHARACTER       matdescra(*)
    INTEGER        m, n, k, ldb, ldc
    INTEGER        indx(*), pntrb(k), pntre(k)
    REAL*8         alpha, beta
    REAL*8         val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dcscmm(char *transa, int *m, int *n, int *k,
    double *alpha, char *matdescra, double *val, int *indx,
    int *pntrb, int *pntre, double *b, int *ldb,
    double *beta, double *c, int *ldc);
```

mkl_dcoomm

Computes matrix-matrix product of a sparse matrix stored in the coordinate format.

Syntax

Fortran:

```
call mkl_dcoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz,
    b, ldb, beta, c, ldc)
```

C:

```
mkl_dcoomm(&transa, &m, &n, &k, &alpha, matdescra, val, rowind, colind, &nnz,
    b, &ldb, &beta, c, &ldc);
```

Description

The `mk1_dcoomm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the coordinate format, *A'* is the transpose of *A*.

NOTE. This routine supports coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.

<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>. Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i>. Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i>, <i>n</i>) for one-based indexing, and (<i>m</i>, <i>ldb</i>) for zero-based indexing. On entry with <i>transa</i> = 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i>.
<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i>, <i>n</i>) for one-based indexing, and (<i>m</i>, <i>ldc</i>) for zero-based indexing. On entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix ($\alpha * A * B + \beta * C$) or ($\alpha * A' * B + \beta * C$).

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcoomm(transa, m, n, k, alpha, matdescra, val,
    rowind, colind, nnz, b, ldb, beta, c, ldc)
    CHARACTER*1    transa
    CHARACTER       matdescra(*)
    INTEGER         m, n, k, ldb, ldc, nnz
    INTEGER         rowind(*), colind(*)
    REAL*8          alpha, beta
    REAL*8          val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dcoomm(char *transa, int *m, int *n, int *k,
    double *alpha,
    char *matdescra, double *val, int *rowind, int *colind, int *nnz,
    double *b, int *ldb, double *beta, double *c, int *ldc);
```

mkl_dcsrsm

Solves a system of linear matrix equations for a sparse matrix in the CSR format.

Syntax

Fortran:

```
call mkl_dcsrsm(transa, m, n, alpha, matdescra, val, indx, pntrb, pntre, b,
    ldb, c, ldc)
```

C:

```
mkl_dcsrsm(&transa, &m, &n, &alpha, matdescra, val, indx, pntrb, pntre, b,
    &ldb, c, &ldc);
```

Description

The `mkl_dcsrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSR format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B,$
<i>m</i>	INTEGER. Number of columns of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix C .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix A . For one-based indexing its length is $\text{pntrc}(m) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrc}(m-1) - \text{pntrb}(0)$.

Refer to *values* array description in [CSR Format](#) for more details.

indx INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.

Refer to *columns* array description in [CSR Format](#) for more details.

NOTE. Column indices must be sorted in increasing order for each row.

pntrb INTEGER. Array of length *m*.

For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row *i* in the arrays *val* and *indx*.

For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row *i* in the arrays *val* and *indx*. Refer to *pointerb* array description in [CSR Format](#) for more details.

pntrr INTEGER. Array of length *m*.

For one-based indexing this array contains row indices, such that $pntrr(i) - pntrb(1)$ is the last index of row *i* in the arrays *val* and *indx*.

For zero-based indexing this array contains row indices, such that $pntrr(i) - pntrb(0) - 1$ is the last index of row *i* in the arrays *val* and *indx*. Refer to *pointerE* array description in [CSR Format](#) for more details.

b REAL*8.

Array, DIMENSION (*ldb*, *n*) for one-based indexing, and (*m*, *ldb*) for zero-based indexing.

On entry the leading *m*-by-*n* part of the array *b* must contain the matrix *B*.

ldb INTEGER. Specifies the first dimension of *b* for one-based indexing, and the second dimension of *b* for zero-based indexing, as declared in the calling (sub)program.

ldc INTEGER. Specifies the first dimension of *c* for one-based indexing, and the second dimension of *c* for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c REAL*8.
 Array, DIMENSION (*ldc*, *n*) for one-based indexing, and (*m*, *ldc*) for zero-based indexing.
 The leading *m*-by-*n* part of the array *c* contains the output matrix *C*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrsm(transa, m, n, alpha, matdescra, val, indx,
  pntreb, pntre, b, ldb, c, ldc)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, n, ldb, ldc
  INTEGER      indx(*), pntreb(m), pntre(m)
  REAL*8       alpha
  REAL*8       val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dcsrsm(char *transa, int *m, int *n, double *alpha,
  char *matdescra, double *val, int *indx, int *pntreb,
  int *pntre, double *b, int *ldb, double *c, int *ldc);
```

mkl_dcscsm

Solves a system of linear matrix equations for a sparse matrix in the CSC format.

Syntax

Fortran:

```
call mkl_dcscsm(transa, m, n, alpha, matdescra, val, indx, pntrb, pntre, b,
ldb, c, ldc)
```

C:

```
mkl_dcscsm(&transa, &m, &n, &alpha, matdescra, val, indx, pntrb, pntre, b,
&ldb, c, &ldc);
```

Description

The `mkl_dcscsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSC format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

transa CHARACTER*1. Specifies the system of equations.
If *transa* = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$

	If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$,
<i>m</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is $\text{pntrb}(k) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrb}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSC Format for more details.
<i>indx</i>	INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i> . Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details.

NOTE. Row indices must be sorted in increasing order for each column.

<i>pntrb</i>	INTEGER. Array of length <i>m</i> . For one-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(1) + 1$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i> . For zero-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(0)$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i> . Refer to <i>pointerb</i> array description in CSC Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i> .

For one-based indexing this array contains column indices, such that $\text{pntrc}(i) - \text{pntrb}(1)$ is the last index of column i in the arrays val and indx .

For zero-based indexing this array contains column indices, such that $\text{pntrc}(i) - \text{pntrb}(1) - 1$ is the last index of column i in the arrays val and indx .

Refer to *pointerE* array description in [CSC Format](#) for more details.

b

REAL*8.

Array, DIMENSION (ldb, n) for one-based indexing, and (m, ldb) for zero-based indexing.

On entry the leading m -by- n part of the array b must contain the matrix B .

ldb

INTEGER. Specifies the first dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.

ldc

INTEGER. Specifies the first dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c

REAL*8.

Array, DIMENSION (ldc, n) for one-based indexing, and (m, ldc) for zero-based indexing.

The leading m -by- n part of the array c contains the output matrix C .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcscsm(transa, m, n, alpha, matdescra, val, indx,  
  pntrb, pntre, b, ldb, c, ldc)  
  
  CHARACTER*1  transa  
  
  CHARACTER    matdescra(*)  
  
  INTEGER      m, n, ldb, ldc  
  
  INTEGER      indx(*), pntrb(m), pntre(m)  
  
  REAL*8       alpha  
  
  REAL*8       val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dcscsm(char *transa, int *m, int *n, double *alpha,  
  char *matdescra, double *val, int *indx, int *pntrb,  
  int *pntre, double *b, int *ldb, double *c, int *ldc);
```

mkl_dcoosm

*Solves a system of linear matrix equations for a
sparse matrix in the coordinate format.*

Syntax

Fortran:

```
call mkl_dcoosm(transa, m, n, alpha, matdescra, val, rowind, colind, nnz, b,  
  ldb, c, ldc)
```

C:

```
mkl_dcoosm(&transa, &m, &n, &alpha, matdescra, val, rowind, colind, &nnz, b,  
  &ldb, c, &ldc);
```

Description

The `mkl_dcoosm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the coordinate format:

`C := alpha*inv(A)*B`

or

`C := alpha*inv(A')*B,`

where:

alpha is scalar, *B* and *C* are dense matrices, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE. This routine supports coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as <code>C := alpha*inv(A)*B</code> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as <code>C := alpha*inv(A')*B,</code>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.

<i>rowind</i>	INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>. Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i>. Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i>, <i>n</i>) for one-based indexing, and (<i>m</i>, <i>ldb</i>) for zero-based indexing. Before entry the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i>, <i>n</i>) for one-based indexing, and (<i>m</i>, <i>ldc</i>) for zero-based indexing. The leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> contains the output matrix <i>C</i>.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcoosm(transa, m, n, alpha, matdescra, val, rowind, colind, nnz, b, ldb, c,
  ldc)

  CHARACTER*1    transa

  CHARACTER      matdescra(*)

  INTEGER        m, n, ldb, ldc, nnz

  INTEGER        rowind(*), colind(*)

  REAL*8         alpha

  REAL*8         val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dcoosm(char *transa, int *m, int *n, double *alpha, char *matdescra,
  double *val, int *rowind, int *colind, int *nnz, double *b, int *ldb, double *c, int *ldc);
```

mkl_dbsrsm

Solves a system of linear matrix equations for a sparse matrix in the BSR format.

Syntax

Fortran:

```
call mkl_dcsrsm(transa, m, n, lb, alpha, matdescra, val, indx, pntreb, pntre,
  b, ldb, c, ldc)
```

C:

```
mkl_dcsrsm(&transa, &m, &n, &lb, &alpha, matdescra, val, indx, pntreb, pntre,
  b, &ldb, c, &ldc);
```

Description

The `mkl_dbsrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the BSR format:

$$C := \alpha \cdot \text{inv}(A) \cdot B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * \text{inv}(A) * B$. If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * \text{inv}(A') * B$.
<i>m</i>	INTEGER. Number of block columns of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix C .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Array containing elements of non-zero blocks of the matrix A . Its length is equal to the <i>ABAB</i> number <i>ABAB</i> of non-zero blocks in the matrix A multiplied by $lb * lb$. Refer to the <i>values</i> array description in BSR Format for more details.

<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i>. For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntre</i>	INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntre(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i>. For zero-based indexing this array contains row indices, such that $pntre(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i>. Refer to <i>pointerE</i> array description in BSR Format for more details.
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i>, <i>n</i>) for one-based indexing, DIMENSION (<i>m</i>, <i>ldb</i>) for zero-based indexing. On entry the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension (in blocks) of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the first dimension (in blocks) of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i>, <i>n</i>) for one-based indexing, DIMENSION (<i>m</i>, <i>ldc</i>) for zero-based indexing.

The leading m -by- n part of the array c contains the output matrix C .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dbsrsm(transa, m, n, lb, alpha, matdescra, val, indx, pntrb, pntre, b, ldb,
c, ldc)

  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, n, lb, ldb, ldc
  INTEGER      indx(*), pntrb(m), pntre(m)
  REAL*8       alpha
  REAL*8       val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dbsrsm(char *transa, int *m, int *n, int *lb, double *alpha, char *matdescra,
double *val, int *indx, int *pntrb, int *pntre, double *b, int *ldb, double *c, int *ldc);
```

mkl_ddiamv

Computes matrix - vector product for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_ddiamv(transa, m, k, alpha, matdescra, val, lval, idiag, ndiag, x,
beta, y)
```

C:

```
mkl_ddiamv(&transa, &m, &k, &alpha, matdescra, val, &lval, idiag, &ndiag, x,
&beta, y);
```

Description

The `mkl_ddiamv` routine performs a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A' * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* sparse matrix stored in the diagonal format, *A'* is the transpose of *A*.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A' * x + \beta * y$.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.

<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	REAL*8. Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n', and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> if <i>transa</i> = 'N' or 'n', and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> .

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_ddiamv(transa, m, k, alpha, matdescra, val, lval, idiag,
ndiag, x, beta, y)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, k, lval, ndiag
  INTEGER      idiag(*)
  REAL*8       alpha, beta
  REAL*8       val(lval,*), x(*), y(*)
```

C:

```
void mkl_ddiamv(char *transa, int *m, int *k, double *alpha,
char *matdescra, double *val, int *lval, int *idiag,
int *ndiag, double *x, double *beta, double *y);
```

mkl_dskymv

Computes matrix - vector product for a sparse matrix in the skyline storage format with one-based indexing.

Syntax

Fortran:

```
call mkl_dskymv(transa, m, k, alpha, matdescra, val, pntr, x, beta, y)
```

C:

```
mkl_dskymv(&transa, &m, &k, &alpha, matdescra, val, pntr, x, &beta, y);
```

Description

The `mkl_dskymv` routine performs a matrix-vector operation defined as

$y := \alpha A x + \beta y$

or

$y := \alpha * A' * x + \beta * y,$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix stored using the skyline storage scheme, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A' * x + \beta * y,$
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL*8. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .

NOTE. General matrices (*matdescra* (1)='G') is not supported.

<i>val</i>	REAL*8. Array containing the set of elements of the matrix A in the skyline profile form. If <i>matdescra</i> (2)= 'L', then <i>val</i> contains elements from the low triangle of the matrix A .

	If <code>matdescrsa(2) = 'U'</code>, then <code>val</code> contains elements from the upper triangle of the matrix <code>A</code>. Refer to <code>values</code> array description in Skyline Storage Scheme for more details.
<code>pntr</code>	INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle. It contains the indices specifying in the <code>val</code> the positions of the first element in each row (column) of the matrix <code>A</code>. Refer to <code>pointers</code> array description in Skyline Storage Scheme for more details.
<code>x</code>	REAL*8. Array, DIMENSION at least k if <code>transa = 'N'</code> or <code>'n'</code> and at least m otherwise. On entry, the array <code>x</code> must contain the vector <code>x</code>.
<code>beta</code>	REAL*8. Specifies the scalar <code>beta</code>.
<code>y</code>	REAL*8. Array, DIMENSION at least m if <code>transa = 'N'</code> or <code>'n'</code> and at least k otherwise. On entry, the array <code>y</code> must contain the vector <code>y</code>.

Output Parameters

<code>y</code>	Overwritten by the updated vector <code>y</code> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dskymv(transa, m, k, alpha, matdescra, val, pntr, x, beta, y)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, k
  INTEGER      pntr(*)
  REAL*8       alpha, beta
  REAL*8       val(*), x(*), y(*)

```

C:

```
void mkl_dskymv (char *transa, int *m, int *k, double *alpha, char *matdescra,  
                double *val, int *pntr, double *x, double *beta, double *y);
```

mkl_ddiasv

Solves a system of linear equations for a sparse matrix in the diagonal format with one-based indexing .

Syntax

Fortran:

```
call mkl_ddiasv(transa, m, alpha, matdescra, val, lval, iddiag, ndiag, x, y)
```

C:

```
mkl_ddiasv(&transa, &m, &alpha, matdescra, val, &lval, iddiag, &ndiag, x, y);
```

Description

The `mkl_ddiasv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

$y := \alpha * \text{inv}(A) * x$

or

$y := \alpha * \text{inv}(A') * x,$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> .

NOTE. All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . The elements are accessed with unit increment.
<i>y</i>	REAL*8. Array, DIMENSION at least <i>m</i> . On entry, the array <i>y</i> must contain the vector <i>y</i> . The elements are accessed with unit increment.

Output Parameters

y Contains solution vector x .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_ddiasv(transa, m, alpha, matdescra, val, lval, idiag, ndiag, x, y)
    CHARACTER*1    transa
    CHARACTER       matdescra(*)
    INTEGER         m, lval, ndiag
    INTEGER         idiag(*)
    REAL*8          alpha
    REAL*8          val(lval,*), x(*), y(*)
```

C:

```
void mkl_ddiasv(char *transa, int *m, double *alpha, char *matdescra,
    double *val, int *lval, int *idiag, int *ndiag, double *x, double *y);
```

mkl_dskysv

Solves a system of linear equations for a sparse matrix in the skyline format with one-based indexing .

Syntax

Fortran:

```
call mkl_dskysv(transa, m, alpha, matdescra, val, pntr, x, y)
```

C:

```
mkl_dskysv(&transa, &m, &alpha, matdescra, val, pntr, x, y);
```

Description

The `mkl_dskysv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the skyline storage format:

`y := alpha*inv(A)*x`

or

`y := alpha*inv(A')*x,`

where:

alpha is scalar, *x* and *y* are vectors, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then <code>y := alpha*inv(A)*x</code> If <i>transa</i> = 'T' or 't' or 'C' or 'c', then <code>y := alpha*inv(A')* x,</code>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .

NOTE. General matrices (*matdescra* (1)='G') is not supported.

<i>val</i>	REAL*8. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form.

	If <code>matdescrsa(2) = 'L'</code>, then <code>val</code> contains elements from the low triangle of the matrix <code>A</code>. If <code>matdescrsa(2) = 'U'</code>, then <code>val</code> contains elements from the upper triangle of the matrix <code>A</code>. Refer to <code>values</code> array description in Skyline Storage Scheme for more details.
<code>pntr</code>	INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle. It contains the indices specifying in the <code>val</code> the positions of the first element in each row (column) of the matrix <code>A</code>. Refer to <code>pointers</code> array description in Skyline Storage Scheme for more details.
<code>x</code>	REAL*8. Array, DIMENSION at least <code>m</code>. On entry, the array <code>x</code> must contain the vector <code>x</code>. The elements are accessed with unit increment.
<code>y</code>	REAL*8. Array, DIMENSION at least <code>m</code>. On entry, the array <code>y</code> must contain the vector <code>y</code>. The elements are accessed with unit increment.

Output Parameters

<code>y</code>	Contains solution vector <code>x</code> .

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dskysv(transa, m, alpha, matdescra, val, pntr, x, y)

  CHARACTER*1    transa
  CHARACTER      matdescra(*)
  INTEGER        m
  INTEGER        pntr(*)
  REAL*8         alpha
  REAL*8         val(*), x(*), y(*)

```

C:

```
void mkl_dskysv(char *transa, int *m, double *alpha, char *matdescra,
               double *val, int *pntr, double *x, double *y);
```

mkl_ddiamm

Computes matrix-matrix product of a sparse matrix stored in the diagonal format with one-based indexing.

Syntax**Fortran:**

```
call mkl_ddiamm(transa, m, n, k, alpha, matdescra, val, lval, idiag, ndiag,
               b, ldb, beta, c, ldc)
```

C:

```
mkl_ddiamm(&transa, &m, &n, &k, &alpha, matdescra, val, &lval, idiag, &ndiag,
           b, &ldb, &beta, c, &ldc);
```

Description

The `mkl_ddiamm` routine performs a matrix-matrix operation defined as

$$C := \alpha A * B + \beta A * C$$

or

$$C := \alpha A' * B + \beta A' * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the diagonal format, *A'* is the transpose of *A*.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i> , <i>n</i>). On entry with <i>transa</i> = 'N' or 'n', the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> , otherwise the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .

<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program.
<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> .
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix ($\alpha * A * B + \beta * C$) or ($\alpha * A' * B + \beta * C$).

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_ddiamm(transa, m, n, k, alpha, matdescra, val, lval,
    idiag, ndiag, b, ldb, beta, c, ldc)
    CHARACTER*1    transa
    CHARACTER       matdescra(*)
    INTEGER         m, n, k, ldb, ldc, lval, ndiag
    INTEGER         idiag(*)
    REAL*8          alpha, beta
    REAL*8          val(lval,*), b(ldb,*), c(ldc,*)

```

C:

```

void mkl_ddiamm(char *transa, int *m, int *n, int *k, double *alpha,
    char *matdescra, double *val, int *lval, int *idiag, int *ndiag,
    double *b, int *ldb, double *beta, double *c, int *ldc);

```

mkl_dskymm

Computes matrix-matrix product of a sparse matrix stored using the skyline storage scheme with one-based indexing .

Syntax

Fortran:

```
call mkl_dskymm(transa, m, n, k, alpha, matdescra, val, pntr, b, ldb, beta,
c, ldc)
```

C:

```
mkl_dskymm(&transa, &m, &n, &k, &alpha, matdescra, val, pntr, b, &ldb, &beta,
c, &ldc);
```

Description

The `mkl_dskymm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the skyline storage format, *A'* is the transpose of *A*.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$,

If *transa* = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,

m INTEGER. Number of rows of the matrix *A*.

n INTEGER. Number of columns of the matrix *C*.

k INTEGER. Number of columns of the matrix *A*.

alpha REAL*8. Specifies the scalar *alpha*.

matdescra CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the [Table 2-6](#).

NOTE. General matrices (*matdescra*(1)='G') is not supported.

val REAL*8. Array containing the set of elements of the matrix *A* in the skyline profile form.
 If *matdescrsa*(2) = 'L', then *val* contains elements from the low triangle of the matrix *A*.
 If *matdescrsa*(2) = 'U', then *val* contains elements from the upper triangle of the matrix *A*.
 Refer to *values* array description in [Skyline Storage Scheme](#) for more details.

pntr INTEGER. Array of length (*m*+*m*) for lower triangle, and (*k*+*k*) for upper triangle.
 It contains the indices specifying in the *val* the positions of the first element in each row (column) of the matrix *A*. Refer to *pointers* array description in [Skyline Storage Scheme](#) for more details.

b REAL*8.
 Array, DIMENSION (*ldb*, *n*).
 On entry with *transa* = 'N' or 'n', the leading *k*-by-*n* part of the array *b* must contain the matrix *B*, otherwise the leading *m*-by-*n* part of the array *b* must contain the matrix *B*.

ldb INTEGER. Specifies the first dimension of *b* as declared in the calling (sub)program.

<i>beta</i>	REAL*8. Specifies the scalar <i>beta</i> .
<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> .
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix ($\alpha * A * B + \beta * C$) or ($\alpha * A' * B + \beta * C$).

Interfaces

FORTRAN 77:

```

SUBROUTINE mkl_dskymm(transa, m, n, k, alpha, matdescra, val, pntr, b,
ldb, beta, c, ldc)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, n, k, ldb, ldc
  INTEGER      pntr(*)
  REAL*8       alpha, beta
  REAL*8       val(*), b(ldb,*), c(ldc,*)

```

C:

```

void mkl_dskymm(char *transa, int *m, int *n, int *k, double *alpha,
char *matdescra, double *val, int *pntr, double *b, int *ldb,
double *beta, double *c, int *ldc);

```

mkl_ddiasm

Solves a system of linear matrix equations for a sparse matrix in the diagonal format with one-based indexing .

Syntax

Fortran:

```
call mkl_ddiasm(transa, m, n, alpha, matdescra, val, lval, idiag, ndiag, b,
ldb, c, ldc)
```

C:

```
mkl_ddiasm(&transa, &m, &n, &alpha, matdescra, val, &lval, idiag, &ndiag, b,
&ldb, c, &ldc);
```

Description

The `mkl_ddiasm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the diagonal format:

$$C := \alpha \cdot \text{inv}(A) \cdot B$$

or

$$C := \alpha \cdot \text{inv}(A') \cdot B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the system of linear equations.
If *transa* = 'N' or 'n', then $C := \alpha \cdot \text{inv}(A) \cdot B$,

	If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .
<i>val</i>	REAL*8. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> .

NOTE. All elements of this array must be sorted in increasing order.

	Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i> , <i>n</i>). On entry the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.

Output Parameters

c REAL*8.
 Array, DIMENSION (*ldc*, *n*).
 The leading *m*-by-*n* part of the array *c* contains the matrix *C*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_ddiasm(transa, m, n, alpha, matdescra, val, lval, idiag,
ndiag, b, ldb, c, ldc)

  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, n, ldb, ldc, lval, ndiag
  INTEGER      idiag(*)
  REAL*8       alpha
  REAL*8       val(lval,*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_ddiasm(char *transa, int *m, int *n, double *alpha,
char *matdescra, double *val, int *lval, int *idiag, int *ndiag,
double *b, int *ldb, double *c, int *ldc);
```

mkl_dskysm

Solves a system of linear matrix equations for a sparse matrix stored using the skyline storage scheme with one-based indexing .

Syntax

Fortran:

```
call mkl_dskysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
```

C:

```
mkl_dskysm(&transa, &m, &n, &alpha, matdescra, val, pntr, b, &ldb, c, &ldc);
```

Description

The `mkl_dskysm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the skyline storage format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

alpha is scalar, *B* and *C* are dense matrices, *A* is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, *A'* is the transpose of *A*.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL*8. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in the Table 2-6 .

NOTE. General matrices (*matdescra* (1)='G') is not supported.

<i>val</i>	REAL*8. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescrsa</i>(2) = 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i>. If <i>matdescrsa</i>(2) = 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i>. Refer to <i>values</i> array description in Skyline Storage Scheme for more details.
<i>pntr</i>	INTEGER. Array of length $(m+m)$. It contains the indices specifying in the <i>val</i> the positions of the first non-zero element of each <i>i</i>-row (column) of the matrix <i>A</i> such that <i>pointers</i>(<i>i</i>) - <i>pointers</i>(1)+1. Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.
<i>b</i>	REAL*8. Array, DIMENSION (<i>ldb</i>, <i>n</i>). On entry the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	REAL*8. Array, DIMENSION (<i>ldc</i>, <i>n</i>). The leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> contains the matrix <i>C</i>.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dskysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
  CHARACTER*1  transa
  CHARACTER    matdescra(*)
  INTEGER      m, n, ldb, ldc
  INTEGER      pntr(*)
  REAL*8       alpha
  REAL*8       val(*), b(ldb,*), c(ldc,*)
```

C:

```
void mkl_dskysm(char *transa, int *m, int *n, double *alpha, char *matdescra,
  double *val, int *pntr, double *b, int *ldb, double *c, int *ldc,);
```

LAPACK Routines: Linear Equations

3

This chapter describes the Intel® Math Kernel Library implementation of routines from the LAPACK package that are used for solving systems of linear equations and performing a number of related computational tasks. The library includes LAPACK routines for both real and complex data. Routines are supported for systems of equations with the following types of matrices:

- general
- banded
- symmetric or Hermitian positive-definite (both full and packed storage)
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian indefinite (both full and packed storage)
- symmetric or Hermitian indefinite banded
- triangular (both full and packed storage)
- triangular banded
- tridiagonal.

For each of the above matrix types, the library includes routines for performing the following computations:

- factoring the matrix (except for triangular matrices)
- equilibrating the matrix
- solving a system of linear equations
- estimating the condition number of a matrix
- refining the solution of linear equations and computing its error bounds
- inverting the matrix.

To solve a particular problem, you can call two or more [computational routines](#) or call a corresponding [driver routine](#) that combines several tasks in one call, such as `?gesv` for factoring and solving. For example, to solve a system of linear equations with a general matrix, call `?getrf` (*LU* factorization) and then `?getrs` (computing the solution). Then, call `?gerfs` to refine the solution and get the error bounds. Alternatively, use the driver routine `?gesvx` that performs all these tasks in one call.

WARNING. LAPACK routines expect that input matrices do not contain `INF` or `NaN` values. When input data is inappropriate for LAPACK, problems may arise, including possible hangs.

Starting from release 8.0, Intel MKL along with Fortran 77 interface to LAPACK computational and driver routines also supports Fortran 95 interface which uses simplified routine calls with shorter argument lists. The syntax section of the routine description gives the calling sequence for Fortran 95 interface immediately after Fortran 77 calls.

Routine Naming Conventions

To call each routine introduced in this chapter from the Fortran 77 program, you can use the LAPACK name.

LAPACK names are listed in [Table 3-1](#) and [Table 3-2](#), and have the structure `?yyzzz` or `?yyzz`, which is described below.

The initial symbol `?` indicates the data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision

The second and third letters `yy` indicate the matrix type and storage scheme:

ge	general
gb	general band
gt	general tridiagonal
po	symmetric or Hermitian positive-definite
pp	symmetric or Hermitian positive-definite (packed storage)
pb	symmetric or Hermitian positive-definite band
pt	symmetric or Hermitian positive-definite tridiagonal
sy	symmetric indefinite
sp	symmetric indefinite (packed storage)
he	Hermitian indefinite
hp	Hermitian indefinite (packed storage)
tr	triangular
tp	triangular (packed storage)
tb	triangular band

For computational routines, the last three letters `zzz` indicate the computation performed:

trf	form a triangular matrix factorization

<code>trs</code>	solve the linear system with a factored matrix
<code>con</code>	estimate the matrix condition number
<code>rfs</code>	refine the solution and compute error bounds
<code>tri</code>	compute the inverse matrix using the factorization
<code>equ</code>	equilibrate a matrix.

For example, the `sgetrf` routine performs the triangular factorization of general real matrices in single precision; the corresponding routine for complex matrices is `cgetrf`.

For driver routines, the names can end with `-sv` (meaning a *simple* driver), or with `-svx` (meaning an *expert* driver).

Names of the LAPACK computational and driver routines for Fortran 95 interface in Intel MKL are the same as Fortran 77 names but without the first letter that indicates the data type. For example, the name of the routine that performs triangular factorization of general real matrices in Fortran 95 interface is `getrf`. Different data types are handled through defining a specific internal parameter that refers to a module block with named constants for single and double precision.

Fortran 95 Interface Conventions

Fortran 95 interface to LAPACK is implemented through wrappers that call respective Fortran 77 routines. This interface uses such features of Fortran 95 as assumed-shape arrays and optional arguments to provide simplified calls to LAPACK routines with fewer arguments.

NOTE. For LAPACK, Intel MKL offers two types of Fortran 95 interfaces:

- using `mkl_lapack.fi` only through `include 'mkl_lapack.fi'` statement. Such interfaces allow you to make use of the original LAPACK routines with all their arguments
 - using `mkl_lapack.f90` that includes improved interfaces described below. This file is used to generate the module files `mkl95_lapack.mod` and `mkl95_precision.mod`. See also section “Fortran 95 interfaces and wrappers to LAPACK and BLAS” of *Intel® MKL User's Guide* for details. The module files are used to process the FORTRAN use clauses referencing the LAPACK interface: `use mkl95_lapack` and `use mkl95_precision`.
-

The main conventions for Fortran 95 interface are as follows:

- The names of arguments used in Fortran 95 call are typically the same as for the respective generic (Fortran 77) interface. However, to reduce the number of argument names used in the library, Fortran 95 interface uses the following identity settings of formal argument names:

Generic Argument Name	Fortran 95 Argument Name
<i>ap</i>	<i>a</i>
<i>ab</i>	<i>a</i>
<i>afb</i>	<i>af</i>
<i>afp</i>	<i>af</i>
<i>bp</i>	<i>b</i>
<i>bb</i>	<i>b</i>
<i>selctg</i>	<i>select</i>

Note that these name changes of formal arguments have no impact on program semantics and follow the unification conventions.

- Input arguments such as array dimensions are not required in Fortran 95 and are skipped from the calling sequence. Array dimensions are reconstructed from the user data that must exactly follow the required array shape.

Another type of generic arguments that are skipped in Fortran 95 interface are arguments that represent workspace arrays (such as *work*, *rwork*, and so on). The only exception are cases when workspace arrays return significant information on output.

An argument can also be skipped if its value is completely defined by the presence or absence of another argument in the calling sequence, and the restored value is the only meaningful value for the skipped argument.

- Some generic arguments are declared as optional in Fortran 95 interface and may or may not be present in the calling sequence. An argument can be declared optional if it satisfies one of the following conditions:
 - If the argument value is completely defined by the presence or absence of another argument in the calling sequence, it can be declared as optional. The difference from the skipped argument in this case is that the optional argument can have some meaningful values that are distinct from the value reconstructed by default. For example, if some

argument (like *jobz*) can take only two values and one of these values directly implies the use of another argument, then the value of *jobz* can be uniquely reconstructed from the actual presence or absence of this second argument, and *jobz* can be omitted.

- If an input argument can take only a few possible values, it can be declared as optional. The default value of such argument is typically set as the first value in the list and all exceptions to this rule are explicitly stated in the routine description.
- If an input argument has a natural default value, it can be declared as optional. The default value of such optional argument is set to its natural default value.
- Argument *info* is declared as optional in Fortran 95 interface. If it is present in the calling sequence, the value assigned to *info* is interpreted as follows:
 - If this value is more than -1000, its meaning is the same as in Fortran 77 routine.
 - If this value is equal to -1000, it means that there is not enough work memory.
 - If this value is equal to -1001, incompatible arguments are present in the calling sequence.
- Optional arguments are given in square brackets in Fortran 95 call syntax.

“Fortran 95 Notes” subsection at the end of the topic describing each routine details concrete rules for reconstructing the values of omitted optional parameters.

Intel® MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation

The following list presents general digressions of the Intel MKL LAPACK95 implementation from the Netlib analog:

- Intel MKL Fortran 95 interfaces are provided for pure procedures.
- Names of interfaces do not contain the `LA_` prefix.
- An optional array argument always has the `target` attribute.
- Functionality of the Intel MKL LAPACK95 wrapper is close to the Fortran 77 original implementation in the `getrf`, `gbtrf`, and `potrf` interfaces.
- If *jobz* argument value specifies presence or absence of *z* argument, then *z* is always declared as optional and *jobz* is restored depending on whether *z* is present or not. It is not always so in the Netlib version (see “[Modified Netlib Interfaces](#)” in Appendix E).
- To avoid double error checking, processing of the *info* argument is limited to checking of the allocated memory and disarranging of optional arguments.
- If an argument that is present in the list of arguments completely defines another argument, the latter is always declared as optional.

You can transform an application that uses the Netlib LAPACK interfaces to ensure its work with the Intel MKL interfaces providing that:

- a.** The application is correct, that is, unambiguous, compiler-independent, and contains no errors.
- b.** Each routine name denotes only one specific routine. If any routine name in the application coincides with a name of the original Netlib routine (for example, after removing the `LA_` prefix) but denotes a routine different from the Netlib original routine, this name should be modified through context name replacement.

You should transform your application in the following cases (see Appendix E for specific differences of individual interfaces):

- When using the Netlib routines that differ from the Intel MKL routines only by the `LA_` prefix or in the array attribute `target`. The only transformation required in this case is context name replacement. See [“Interfaces Identical to Netlib”](#) in Appendix E for details.
- When using Netlib routines that differ from the Intel MKL routines by the `LA_` prefix, the `target` array attribute, and the names of formal arguments. In the case of positional passing of arguments, no additional transformation except context name replacement is required. In the case of the keywords passing of arguments, in addition to the context name replacement the names of mismatching keywords should also be modified. See [“Interfaces with Replaced Argument Names”](#) in Appendix E for details.
- When using the Netlib routines that differ from the respective Intel MKL routines by the `LA_` prefix, the `target` array attribute, sequence of the arguments, arguments missing in Intel MKL but present in Netlib and, vice versa, present in Intel MKL but missing in Netlib. Remove the differences in the sequence and range of the arguments in process of all the transformations when you use the Netlib routines specified by this bullet and the preceding bullet. See [“Modified Netlib Interfaces”](#) in Appendix E for details.
- When using the `getrf`, `gbtrf`, and `potrf` interfaces, that is, new functionality implemented in Intel MKL but unavailable in the Netlib source. To override the differences, build the desired functionality explicitly with the Intel MKL means or create a new subroutine with the new functionality, using specific MKL interfaces corresponding to LAPACK 77 routines. You can call the LAPACK 77 routines directly but using the new Intel MKL interfaces is preferable. See [“Interfaces Absent From Netlib”](#) and [“Interfaces of New Functionality”](#) in Appendix E for details.

Note that if the transformed application calls `getrf`, `gbtrf` or `potrf` without controlling arguments `rcond` and `norm`, just context name replacement is enough in modifying the calls into the Intel MKL interfaces, as described in the first bullet above. The Netlib functionality is preserved in such cases.

- When using the Netlib auxiliary routines. In this case, call a corresponding subroutine directly, using the MKL LAPACK 77 interfaces.

Transform your application as follows:

- 1.** Make sure conditions a. and b. are met.

2. Select Netlib LAPACK 95 calls. For each call do the following:
 - Select the type of digression and do the required transformations.
 - Revise results to eliminate unneeded code or data, which may appear after several identical calls.
3. Make sure the transformations are correct and complete.

Matrix Storage Schemes

LAPACK routines use the following matrix storage schemes:

- *Full storage*: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: an m -by- n band matrix with kl sub-diagonals and ku superdiagonals is stored compactly in a two-dimensional array ab with $kl+ku+1$ rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

In Chapters 4 and 5, arrays that hold matrices in packed storage have names ending in p ; arrays with matrices in band storage have names ending in b .

For more information on matrix storage schemes, see “[Matrix Arguments](#)” in Appendix B.

Mathematical Notation

Descriptions of LAPACK routines use the following notation:

$Ax = b$	A system of linear equations with an n -by- n matrix $A = \{a_{ij}\}$, a right-hand side vector $b = \{b_i\}$, and an unknown vector $x = \{x_i\}$.
$AX = B$	A set of systems with a common matrix A and multiple right-hand sides. The columns of B are individual right-hand sides, and the columns of X are the corresponding solutions.
$ x $	the vector with elements $ x_i $ (absolute values of x_i).
$ A $	the matrix with elements $ a_{ij} $ (absolute values of a_{ij}).
$\ x\ _\infty = \max_i x_i $	The <i>infinity-norm</i> of the vector x .

$$\|A\|_{\infty} = \max_j \sum_i |a_{ij}|$$

The *infinity-norm* of the matrix A .

$$\|A\|_1 = \max_i \sum_j |a_{ij}|$$

The *one-norm* of the matrix A . $\|A\|_1 = \|A^T\|_{\infty} = \|A^H\|_{\infty}$

$$\kappa(A) = \|A\| \|A^{-1}\|$$

The *condition number* of the matrix A .

Error Analysis

In practice, most computations are performed with rounding errors. Besides, you often need to solve a system $Ax = b$, where the data (the elements of A and b) are not known exactly. Therefore, it is important to understand how the data errors and rounding errors can affect the solution x .

Data perturbations. If x is the exact solution of $Ax = b$, and $x + \delta x$ is the exact solution of a perturbed problem $(A + \delta A)x = (b + \delta b)$, then

$$\frac{\|\delta x\|}{\|x\|} \leq \kappa(A) \left(\frac{\|\delta A\|}{\|A\|} + \frac{\|\delta b\|}{\|b\|} \right),$$

where

$$\kappa(A) = \|A\| \|A^{-1}\|.$$

In other words, relative errors in A or b may be amplified in the solution vector x by a factor $\kappa(A) = \|A\| \|A^{-1}\|$ called the *condition number* of A .

Rounding errors have the same effect as relative perturbations $c(n)\varepsilon$ in the original data.

Here ε is the *machine precision*, and $c(n)$ is a modest function of the matrix order n . The corresponding solution error is

$$\|\delta x\| / \|x\| \leq c(n) \kappa(A) \varepsilon. \text{ (The value of } c(n) \text{ is seldom greater than } 10n.)$$

Thus, if your matrix A is *ill-conditioned* (that is, its condition number $\kappa(A)$ is very large), then the error in the solution x is also large; you may even encounter a complete loss of precision. LAPACK provides routines that allow you to estimate $\kappa(A)$ (see [Routines for Estimating the Condition Number](#)) and also give you a more precise estimate for the actual solution error (see [Refining the Solution and Estimating Its Error](#)).

Computational Routines

[Table 3-1](#) lists the LAPACK computational routines (Fortran 77 and Fortran 95 interfaces) for factorizing, equilibrating, and inverting *real* matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error. [Table 3-2](#) lists similar routines for *complex* matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 3-1 Computational Routines for Systems of Equations with Real Matrices

In the table above, `?` stands for `c` (single precision complex) or `z` (double precision complex) for Fortran 77 interface.

Routines for Matrix Factorization

This section describes the LAPACK routines for matrix factorization. The following factorizations are supported:

- *LU* factorization
- Cholesky factorization of real symmetric positive-definite matrices
- Cholesky factorization of Hermitian positive-definite matrices
- Bunch-Kaufman factorization of real and complex symmetric matrices
- Bunch-Kaufman factorization of Hermitian matrices.

You can compute:

- the *LU* factorization using full and band storage of matrices
- the Cholesky factorization using full, packed, and band storage
- the Bunch-Kaufman factorization using full and packed storage.

?getrf

Computes the LU factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgetrf( m, n, a, lda, ipiv, info )
call dgetrf( m, n, a, lda, ipiv, info )
call cgetrf( m, n, a, lda, ipiv, info )
call zgetrf( m, n, a, lda, ipiv, info )
```

Fortran 95:

```
call getrf( a [,ipiv] [,info] )
```

Description

The routine computes the LU factorization of a general m -by- n matrix A as

$$A = P * L * U,$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). Usually A is square ($m = n$), and both L and U are triangular. The routine uses partial pivoting, with row interchanges.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ; $n \geq 0$.
a	REAL for sgetrf DOUBLE PRECISION for dgetrf COMPLEX for cgetrf DOUBLE COMPLEX for zgetrf. Array, DIMENSION ($lda, *$). Contains the matrix A . The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of array a .

Output Parameters

<i>a</i>	Overwritten by <i>L</i> and <i>U</i> . The unit diagonal elements of <i>L</i> are not stored.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices: row <i>i</i> was interchanged with row <i>ipiv</i> (<i>i</i>).
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , <i>u</i> _{<i>ii</i>} is 0. The factorization has been completed, but <i>U</i> is exactly singular. Division by 0 will occur if you use the factor <i>U</i> for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getrf` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>ipiv</i>	Holds the vector of length $\min(m, n)$.

Application Notes

The computed *L* and *U* are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(\min(m, n)) \varepsilon P|L||U|$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

The approximate number of floating-point operations for real flavors is

$(2/3)n^3$	If $m = n$,
$(1/3)n^2(3m-n)$	If $m > n$,
$(1/3)m^2(3n-m)$	If $m < n$.

The number of operations for complex flavors is four times greater.

After calling this routine with $m = n$, you can call the following:

<code>?getrs</code>	to solve $A^*X = B$ or $A^TX = B$ or $A^HX = B$
<code>?gecon</code>	to estimate the condition number of <i>A</i>

`?getri` to compute the inverse of A .

?gbtrf

Computes the LU factorization of a general m -by- n band matrix.

Syntax

FORTRAN 77:

```
call sgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
```

Fortran 95:

```
call gbtrf( a [,kl] [,m] [,ipiv] [,info] )
```

Description

The routine forms the LU factorization of a general m -by- n band matrix A with kl non-zero subdiagonals and ku non-zero superdiagonals. Usually A is square ($m = n$), and then

$$A = P * L * U,$$

where P is a permutation matrix; L is lower triangular with unit diagonal elements and at most kl non-zero elements in each column; U is an upper triangular band matrix with $kl + ku$ superdiagonals. The routine uses partial pivoting, with row interchanges (which creates the additional kl superdiagonals in U).

Input Parameters

m	INTEGER. The number of rows in matrix A ($m \geq 0$).
n	INTEGER. The number of columns in matrix A ; $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
ab	REAL for sgbtrf DOUBLE PRECISION for dgbtrf

COMPLEX for `cgbtrf`

DOUBLE COMPLEX for `zgbtrf`.

Array, DIMENSION ($ldab, *$). The array *ab* contains the matrix *A* in band storage (see [Matrix Storage Schemes](#)). The second dimension of *ab* must be at least $\max(1, n)$.

ldab INTEGER. The first dimension of the array *ab*. ($ldab \geq 2 * kl + ku + 1$)

Output Parameters

ab Overwritten by *L* and *U*. The diagonal and $kl + ku$ superdiagonals of *U* are stored in the first $1 + kl + ku$ rows of *ab*. The multipliers used to form *L* are stored in the next *kl* rows.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices: row *i* was interchanged with row *ipiv*(*i*).

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, u_{ii} is 0. The factorization has been completed, but *U* is exactly singular. Division by 0 will occur if you use the factor *U* for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbtrf` interface are as follows:

a Stands for argument *ab* in Fortran 77 interface. Holds the array *A* of size $(2 * kl + ku + 1, n)$.

ipiv Holds the vector of length $\min(m, n)$.

kl If omitted, assumed $kl = ku$.

ku Restored as $ku = lda - 2 * kl - 1$.

m If omitted, assumed $m = n$.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(kl+ku+1) \varepsilon P|L||U|$$

$c(k)$ is a modest linear function of k , and ε is the machine precision.

The total number of floating-point operations for real flavors varies between approximately $2n(ku+1)kl$ and $2n(kl+ku+1)kl$. The number of operations for complex flavors is four times greater. All these estimates assume that kl and ku are much less than $\min(m, n)$.

After calling this routine with $m = n$, you can call the following routines:

<code>gbtrs</code>	to solve $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$
<code>gbcon</code>	to estimate the condition number of A .

?gttrf

Computes the LU factorization of a tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sgttrf( n, dl, d, du, du2, ipiv, info )
call dgttrf( n, dl, d, du, du2, ipiv, info )
call cgttrf( n, dl, d, du, du2, ipiv, info )
call zgttrf( n, dl, d, du, du2, ipiv, info )
```

Fortran 95:

```
call gttrf( dl, d, du, du2 [, ipiv] [,info] )
```

Description

The routine computes the LU factorization of a real or complex tridiagonal matrix A in the form $A = P^*L^*U$,

where P is a permutation matrix; L is lower bidiagonal with unit diagonal elements; and U is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals. The routine uses elimination with partial pivoting and row interchanges.

Input Parameters

n INTEGER. The order of the matrix *A*; $n \geq 0$.

dl, *d*, *du* REAL for sgttrf
 DOUBLE PRECISION for dgttrf
 COMPLEX for cgttrf
 DOUBLE COMPLEX for zgttrf.
 Arrays containing elements of *A*.
 The array *dl* of dimension $(n - 1)$ contains the subdiagonal elements of *A*.
 The array *d* of dimension *n* contains the diagonal elements of *A*.
 The array *du* of dimension $(n - 1)$ contains the superdiagonal elements of *A*.

Output Parameters

dl Overwritten by the $(n-1)$ multipliers that define the matrix *L* from the *LU* factorization of *A*.

d Overwritten by the *n* diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.

du Overwritten by the $(n-1)$ elements of the first superdiagonal of *U*.

du2 REAL for sgttrf
 DOUBLE PRECISION for dgttrf
 COMPLEX for cgttrf
 DOUBLE COMPLEX for zgttrf.
 Array, dimension $(n-2)$. On exit, *du2* contains $(n-2)$ elements of the second superdiagonal of *U*.

ipiv INTEGER.
 Array, dimension (n) . The pivot indices: row *i* was interchanged with row *ipiv*(*i*).

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, u_{ii} is 0. The factorization has been completed, but *U* is exactly singular. Division by zero will occur if you use the factor *U* for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gttrf` interface are as follows:

<code>d1</code>	Holds the vector of length $(n-1)$.
<code>d</code>	Holds the vector of length (n) .
<code>du</code>	Holds the vector of length $(n-1)$.
<code>du2</code>	Holds the vector of length $(n-2)$.
<code>ipiv</code>	Holds the vector of length (n) .

Application Notes

<code>?gbtrs</code>	to solve $A * X = B$ or $A^T * X = B$ or $A^H * X = B$
<code>?gbcon</code>	to estimate the condition number of A .

?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotrf( uplo, n, a, lda, info )
call dpotrf( uplo, n, a, lda, info )
call cpotrf( uplo, n, a, lda, info )
call zpotrf( uplo, n, a, lda, info )
```

Fortran 95:

```
call potrf( a [, uplo] [,info] )
```

Description

This routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A :

$$A = U^H * U \quad \text{if } uplo = 'U'$$

$$A = L * L^H \quad \text{if } uplo = 'L',$$

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A , and A is factored as $U^H * U$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A ; A is factored as $L * L^H$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i>	REAL for <code>spotrf</code> DOUBLE PRECISION for <code>dpotrf</code> COMPLEX for <code>cpotrf</code> DOUBLE COMPLEX for <code>zpotrf</code> . Array, DIMENSION (<i>lda</i> , *). The array <i>a</i> contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor U or L , as specified by <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `potrf` interface are as follows:

`a` Holds the matrix A of size (n, n) .
`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If `uplo` = 'U', the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for `uplo` = 'L'.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

`?potrs` to solve $A^*X = B$
`?pocon` to estimate the condition number of A
`?potri` to compute the inverse of A .

?pptrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix using packed storage.

Syntax

FORTRAN 77:

```
call spptrf( uplo, n, ap, info )
call dpptrf( uplo, n, ap, info )
call cpptrf( uplo, n, ap, info )
call zpptrf( uplo, n, ap, info )
```

Fortran 95:

```
call ppstrf( a [, uplo] [,info] )
```

Description

This routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite packed matrix A :

$$A = U^H * U \quad \text{if } uplo = 'U'$$

$$A = L * L^H \quad \text{if } uplo = 'L',$$

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is packed in the array *ap*, and how A is factored:
If *uplo* = 'U', the array *ap* stores the upper triangular part of the matrix A , and A is factored as $U^H * U$.
If *uplo* = 'L', the array *ap* stores the lower triangular part of the matrix A ; A is factored as $L * L^H$.

n INTEGER. The order of matrix A ; $n \geq 0$.

ap REAL for spstrf
DOUBLE PRECISION for dpstrf
COMPLEX for cpstrf
DOUBLE COMPLEX for zpstrf.
Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array *ap* contains either the upper or the lower triangular part of the matrix A (as specified by *uplo*) in packed storage (see [Matrix Storage Schemes](#)).

Output Parameters

ap The upper or lower triangular part of A in packed storage is overwritten by the Cholesky factor U or L , as specified by *uplo*.

info INTEGER. If *info*=0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptrf` interface are as follows:

<code>a</code>	Stands for argument <code>ap</code> in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If `uplo = 'U'`, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon |U^H| |U|, |e_{ij}| \leq c(n)\epsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

A similar estimate holds for `uplo = 'L'`.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?pptrs</code>	to solve $A * X = B$
<code>?ppcon</code>	to estimate the condition number of A
<code>?pptri</code>	to compute the inverse of A .

?pbtrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbtrf( uplo, n, kd, ab, ldab, info )
call dpbtrf( uplo, n, kd, ab, ldab, info )
call cpbtrf( uplo, n, kd, ab, ldab, info )
call zpbtrf( uplo, n, kd, ab, ldab, info )
```

Fortran 95:

```
call pbtrf( a [, uplo] [,info] )
```

Description

This routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite band matrix A :

$A = U^T * U$ for real data, if $uplo = 'U'$

$A = U^H * U$ for complex data

$A = L * L^T$ for real data, if $uplo = 'L'$,

$A = L * L^H$ for complex data

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

$uplo$	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored in the array ab , and how A is factored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.

<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ($kd \geq 0$).
<i>ab</i>	REAL for <code>spbtrf</code> DOUBLE PRECISION for <code>dpbtrf</code> COMPLEX for <code>cpbtrf</code> DOUBLE COMPLEX for <code>zpbtrf</code> . Array, DIMENSION ($*$). The array <i>ap</i> contains either the upper or the lower triangular part of the matrix A (as specified by <i>uplo</i>) in band storage (see Matrix Storage Schemes). The second dimension of <i>ab</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq kd + 1$)

Output Parameters

<i>ap</i>	The upper or lower triangular part of A (in band storage) is overwritten by the Cholesky factor U or L , as specified by <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value. If <i>info</i> = i , the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbtrf` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array A of size $(kd+1, n)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If *uplo* = 'U', the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(kd + 1)\varepsilon |U^H| |U|, |e_{ij}| \leq c(kd + 1)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$.

The total number of floating-point operations for real flavors is approximately $n(kd+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that kd is much less than n .

After calling this routine, you can call the following routines:

`?pbtrs` to solve $A^*X = B$
`?pbcon` to estimate the condition number of A .

?pttrf

Computes the factorization of a symmetric (Hermitian) positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call spttrf( n, d, e, info )
call dpttrf( n, d, e, info )
call cpttrf( n, d, e, info )
call zpttrf( n, d, e, info )
```

Fortran 95:

```
call pttrf( d, e [,info] )
```

Description

This routine forms the factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite tridiagonal matrix A :

$$A = L^*D^*L',$$

where D is diagonal and L is unit lower bidiagonal. The factorization may also be regarded as having the form $A = U^*D^*U$, where D is unit upper bidiagonal.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>d</i>	REAL for <code>spttrf</code> , <code>cpttrf</code> DOUBLE PRECISION for <code>dpttrf</code> , <code>zpttrf</code> . Array, dimension (<i>n</i>). Contains the diagonal elements of <i>A</i> .
<i>e</i>	REAL for <code>spttrf</code> DOUBLE PRECISION for <code>dpttrf</code> COMPLEX for <code>cpttrf</code> DOUBLE COMPLEX for <code>zpttrf</code> . Array, dimension (<i>n</i> - 1). Contains the subdiagonal elements of <i>A</i> .

Output Parameters

<i>d</i>	Overwritten by the <i>n</i> diagonal elements of the diagonal matrix <i>D</i> from the L^*D^*L' factorization of <i>A</i> .
<i>e</i>	Overwritten by the (<i>n</i> - 1) off-diagonal elements of the unit bidiagonal factor <i>L</i> or <i>U</i> from the factorization of <i>A</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite; if $i < n$, the factorization could not be completed, while if $i = n$, the factorization was completed, but $d(n) \leq 0$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pttrf` interface are as follows:

<i>d</i>	Holds the vector of length (<i>n</i>).
<i>e</i>	Holds the vector of length (<i>n</i> -1).

?sytrf

Computes the Bunch-Kaufman factorization of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call dsytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call csytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call zsytrf( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call sytrf( a [, uplo] [,ipiv] [, info] )
```

Description

This routine forms the Bunch-Kaufman factorization of a symmetric matrix:

if $uplo = 'U'$, $A = P * U * D * U^T * P^T$
if $uplo = 'L'$, $A = P * L * D * L^T * P^T$,

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored and how A is factored:
If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A , and A is factored as $P * U * D * U^T * P^T$.
If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A , and A is factored as $P * L * D * L^T * P^T$.

n INTEGER. The order of matrix A ; $n \geq 0$.

a REAL for ssytrf
DOUBLE PRECISION for dsytrf
COMPLEX for csytrf
DOUBLE COMPLEX for zsytrf.
Array, DIMENSION (*lda*, *). The array *a* contains either the upper or the lower triangular part of the matrix *A* (see *uplo*). The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

work Same type as *a*. A workspace array, dimension at least $\max(1, lwork)$.

lwork INTEGER. The size of the *work* array ($lwork \geq n$).
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.
See [Application Notes](#) for the suggested value of *lwork*.

Output Parameters

a The upper or lower triangular part of *a* is overwritten by details of the block-diagonal matrix *D* and the multipliers used to obtain the factor *U* (or *L*).

work(1) If *info*=0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of *D*. If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.
If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i-1*, and (*i-1*)-th row and column of *A* was interchanged with the *m*-th row and column.
If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i+1*, and (*i+1*)-th row and column of *A* was interchanged with the *m*-th row and column.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrf` interface are as follows:

<code>a</code>	holds the matrix A of size (n, n)
<code>ipiv</code>	holds the vector of length (n)
<code>uplo</code>	must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array `a`, but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array `a`.

If `uplo = 'U'`, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |P||U||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. A similar estimate holds for the computed L and D when `uplo = 'L'`.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?sytrs</code>	to solve $A^*X = B$
<code>?sycon</code>	to estimate the condition number of A
<code>?sytri</code>	to compute the inverse of A .

?hetrf

Computes the Bunch-Kaufman factorization of a complex Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetrf( uplo, n, a, lda, ipiv, work, lwork, info )
call zhetrf( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call hetrf( a [, uplo] [,ipiv] [,info] )
```

Description

This routine forms the Bunch-Kaufman factorization of a Hermitian matrix:

if `uplo='U'`, $A = P^*U^*D^*U^H*P^T$

if `uplo='L'`, $A = P^*L^*D^*L^H*P^T$,

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A, and A is factored as $P*U*D*U^H*P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A, and A is factored as $P*L*D*L^H*P^T$.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>a, work</i>	COMPLEX for <code>chetr</code> DOUBLE COMPLEX for <code>zhetr</code>. Arrays, DIMENSION $a(lda, *)$, $work(*)$. The array <i>a</i> contains the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array of dimension at least $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code>. See Application Notes for the suggested value of <i>lwork</i>.

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>ipiv</i>	INTEGER.

Array, `DIMENSION` at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and the $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and the $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrf` interface are as follows:

<i>a</i>	holds the matrix A of size (n, n)
<i>ipiv</i>	holds the vector of length (n)
<i>uplo</i>	must be 'U' or 'L'. The default value is 'U'.

Application Notes

This routine is suitable for Hermitian matrices that are not known to be positive-definite. If A is in fact positive-definite, the routine does not perform interchanges, and no 2-by-2 diagonal blocks occur in D .

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The 2-by-2 unit diagonal blocks and the unit diagonal elements of *U* and *L* are not stored. The remaining elements of *U* and *L* are stored in the corresponding columns of the array *a*, but additional row interchanges are required to recover *U* or *L* explicitly (which is seldom necessary).

If *ipiv*(*i*) = *i* for all *i* = 1 . . . *n*, then all off-diagonal elements of *U* (*L*) are stored explicitly in the corresponding elements of the array *a*.

If *uplo* = 'U', the computed factors *U* and *D* are the exact factors of a perturbed matrix *A* + *E*, where

$$|E| \leq c(n) \varepsilon P |U| |D| |U^T| P^T$$

c(*n*) is a modest linear function of *n*, and ε is the machine precision.

A similar estimate holds for the computed *L* and *D* when *uplo* = 'L'.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

<code>?hetrs</code>	to solve $A * X = B$
<code>?hecon</code>	to estimate the condition number of <i>A</i>
<code>?hetri</code>	to compute the inverse of <i>A</i> .

?sptf

Computes the Bunch-Kaufman factorization of a symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptf( uplo, n, ap, ipiv, info )
call dsptf( uplo, n, ap, ipiv, info )
call csptf( uplo, n, ap, ipiv, info )
call zsptf( uplo, n, ap, ipiv, info )
```

Fortran 95:

```
call sptrf( a [,uplo] [,ipiv] [,info] )
```

Description

This routine forms the Bunch-Kaufman factorization of a symmetric matrix A using packed storage:

if $uplo='U'$, $A = P*U*D*U^T*P^T$
 if $uplo='L'$, $A = P*L*D*L^T*P^T$,

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

Input Parameters

$uplo$	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is packed in the array ap and how A is factored: If $uplo = 'U'$, the array ap stores the upper triangular part of the matrix A , and A is factored as $P*U*D*U^T*P^T$. If $uplo = 'L'$, the array ap stores the lower triangular part of the matrix A , and A is factored as $P*L*D*L^T*P^T$.
n	INTEGER. The order of matrix A ; $n \geq 0$.

ap REAL for `ssptf`
 DOUBLE PRECISION for `dsptf`
 COMPLEX for `csptf`
 DOUBLE COMPLEX for `zsptf`.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array *ap* contains the upper or the lower triangular part of the matrix *A* (as specified by *uplo*) in *packed storage* (see [Matrix Storage Schemes](#)).

Output Parameters

ap The upper or lower triangle of *A* (as specified by *uplo*) is overwritten by details of the block-diagonal matrix *D* and the multipliers used to obtain the factor *U* (or *L*).

ipiv INTEGER.
 Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of *D*. If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.
 If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i-1*, and the (*i-1*)-th row and column of *A* was interchanged with the *m*-th row and column.
 If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i+1*, and the (*i+1*)-th row and column of *A* was interchanged with the *m*-th row and column.

info INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the *i*-th parameter had an illegal value.
 If $info = i$, d_{ii} is 0. The factorization has been completed, but *D* is exactly singular. Division by 0 will occur if you use *D* for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptf` interface are as follows:

a stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size $(n * (n+1) / 2)$.

ipiv holds the vector of length (*n*).
uplo must be 'U' or 'L'. The default value is 'U'.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of *U* and *L* are not stored. The remaining elements of *U* and *L* overwrite elements of the corresponding columns of the matrix *A*, but additional row interchanges are required to recover *U* or *L* explicitly (which is seldom necessary).

If *ipiv*(*i*) = *i* for all *i* = 1...*n*, then all off-diagonal elements of *U* (*L*) are stored explicitly in packed form.

If *uplo* = 'U', the computed factors *U* and *D* are the exact factors of a perturbed matrix *A* + *E*, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T$$

c(*n*) is a modest linear function of *n*, and ε is the machine precision. A similar estimate holds for the computed *L* and *D* when *uplo* = 'L'.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

?sptsr to solve $A * X = B$
 ?spcon to estimate the condition number of *A*
 ?sptri to compute the inverse of *A*.

?hptrf

Computes the Bunch-Kaufman factorization of a complex Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptrf( uplo, n, ap, ipiv, info )
call zhptrf( uplo, n, ap, ipiv, info )
```

Fortran 95:

```
call hptrf( a [,uplo] [,ipiv] [,info] )
```

Description

This routine forms the Bunch-Kaufman factorization of a Hermitian matrix using packed storage:

if $uplo='U'$, $A = P*U*D*U^H*P^T$
 if $uplo='L'$, $A = P*L*D*L^H*P^T$,

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

Input Parameters

$uplo$ CHARACTER*1. Must be 'U' or 'L'.
 Indicates whether the upper or lower triangular part of A is packed and how A is factored:
 If $uplo = 'U'$, the array ap stores the upper triangular part of the matrix A , and A is factored as $P*U*D*U^H*P^T$.
 If $uplo = 'L'$, the array ap stores the lower triangular part of the matrix A , and A is factored as $P*L*D*L^H*P^T$.

n INTEGER. The order of matrix A ; $n \geq 0$.

ap COMPLEX for `chptrf`
 DOUBLE COMPLEX for `zhptrf`.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array ap contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in *packed storage* (see [Matrix Storage Schemes](#)).

Output Parameters

ap The upper or lower triangle of A (as specified by $uplo$) is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

$ipiv$ INTEGER.

Array, `DIMENSION` at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and the $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and the $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpztrf` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array a , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array a .

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n) \varepsilon_P |U| |D| |U^T| P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

<code>?hptrs</code>	to solve $A^*X = B$
<code>?hpcon</code>	to estimate the condition number of A
<code>?hptri</code>	to compute the inverse of A .

Routines for Solving Systems of Linear Equations

This section describes the LAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

?getrs

Solves a system of linear equations with an LU-factored square matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call dgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call cgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call zgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call getrs( a, ipiv, b [, trans] [,info] )
```

Description

This routine solves for x the following systems of linear equations:

$A^*X = B$ if $trans = 'N'$,

$A^T * X = B$ if *trans* = 'T',
 $A^H * X = B$ if *trans* = 'C' (for complex matrices only).

Before calling this routine, you must call [?getrf](#) to compute the *LU* factorization of *A*.

Input Parameters

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Indicates the form of the equations:
 If *trans* = 'N', then $A * X = B$ is solved for *X*.
 If *trans* = 'T', then $A^T * X = B$ is solved for *X*.
 If *trans* = 'C', then $A^H * X = B$ is solved for *X*.

n INTEGER. The order of *A*; the number of rows in *B* ($n \geq 0$).

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

a, b REAL for sgetrs
 DOUBLE PRECISION for dgetrs
 COMPLEX for cgetrs
 DOUBLE COMPLEX for zgetrs.
 Arrays: *a*(*lda*,*), *b*(*ldb*,*).
 The array *a* contains *LU* factorization of matrix *A* resulting from the call of [?getrf](#).
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.
 The second dimension of *a* must be at least $\max(1, n)$, the second dimension of *b* at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ipiv INTEGER.
 Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?getrf](#).

Output Parameters

b Overwritten by the solution matrix *X*.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getrs` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|L||U|$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x) \varepsilon$$

where $\operatorname{cond}(A, x) = \frac{\|A^{-1}\|_\infty \|A\|_\infty \|x\|_\infty}{\|x\|_\infty} \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\operatorname{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector *b* is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?gecon](#).

To refine the solution and estimate the error, call [?gerfs](#).

?gbtrs

Solves a system of linear equations with an LU-factored band matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call dgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call cgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call zgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
```

Fortran 95:

```
call gbtrs( a, b, ipiv, [, kl] [, trans] [, info] )
```

Description

This routine solves for X the following systems of linear equations:

$A * X = B$ if $trans = 'N'$,
 $A^T * X = B$ if $trans = 'T'$,
 $A^H * X = B$ if $trans = 'C'$ (for complex matrices only).

Here A is an LU -factored general band matrix of order n with kl non-zero subdiagonals and ku nonzero superdiagonals. Before calling this routine, call [?gbtrf](#) to compute the LU factorization of A .

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.
<i>n</i>	INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for sgbtrs

DOUBLE PRECISION for `dgbtrs`

COMPLEX for `cgbtrs`

DOUBLE COMPLEX for `zgbtrs`.

Arrays: `ab(ldab,*)`, `b(ldb,*)`.

The array `ab` contains the matrix A in *band storage* (see [Matrix Storage Schemes](#)).

The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations.

The second dimension of `ab` must be at least $\max(1, n)$, and the second dimension of `b` at least $\max(1, nrhs)$.

`ldab` INTEGER. The leading dimension of the array `ab`; $ldab \geq 2*kl + ku + 1$.

`ldb` INTEGER. The leading dimension of `b`; $ldb \geq \max(1, n)$.

`ipiv` INTEGER. Array, DIMENSION at least $\max(1, n)$. The `ipiv` array, as returned by `?gbtrf`.

Output Parameters

`b` Overwritten by the solution matrix X .

`info` INTEGER. If `info=0`, the execution is successful.
If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbtrs` interface are as follows:

`a` Stands for argument `ab` in Fortran 77 interface. Holds the array A of size $(2*kl+ku+1, n)$.

`b` Holds the matrix B of size $(n, nrhs)$.

`ipiv` Holds the vector of length $\min(m, n)$.

`kl` If omitted, assumed $kl = ku$.

`ku` Restored as $lda-2*kl-1$.

`trans` Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kl + ku + 1)\varepsilon P|L||U|$$

$c(k)$ is a modest linear function of k , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kl + ku + 1) \text{cond}(A, x) \varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector is $2n(ku + 2kl)$ for real flavors. The number of operations for complex flavors is 4 times greater. All these estimates assume that kl and ku are much less than $\min(m, n)$.

To estimate the condition number $\kappa_\infty(A)$, call [?gbcon](#).

To refine the solution and estimate the error, call [?gbrfs](#).

?gttrs

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf.

Syntax

FORTRAN 77:

```
call sgtrrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call dgtrrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call cgtrrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call zgtrrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
```

Fortran 95:

```
call gttrs( dl, d, du, du2, b, ipiv [, trans] [,info] )
```

Description

This routine solves for x the following systems of linear equations with multiple right hand sides:

$A * X = B$ if $trans = 'N'$,
 $A^T * X = B$ if $trans = 'T'$,
 $A^H * X = B$ if $trans = 'C'$ (for complex matrices only).

Before calling this routine, you must call [?gttrf](#) to compute the LU factorization of A .

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If $trans = 'N'$, then $A * X = B$ is solved for x . If $trans = 'T'$, then $A^T * X = B$ is solved for x . If $trans = 'C'$, then $A^H * X = B$ is solved for x .
<i>n</i>	INTEGER. The order of A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns in B ; $nrhs \geq 0$.

dl,d,du,du2,b REAL for sgttrs
 DOUBLE PRECISION for dgttrs
 COMPLEX for cgttrs
 DOUBLE COMPLEX for zgttrs.
Arrays: *dl*(*n - 1*), *d*(*n*), *du*(*n - 1*), *du2*(*n - 2*), *b*(*ldb,nrhs*).
 The array *dl* contains the (*n - 1*) multipliers that define the matrix *L* from the *LU* factorization of *A*.
 The array *d* contains the *n* diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.
 The array *du* contains the (*n - 1*) elements of the first superdiagonal of *U*.
 The array *du2* contains the (*n - 2*) elements of the second superdiagonal of *U*.
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

ldb INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

ipiv INTEGER. Array, DIMENSION (*n*). The *ipiv* array, as returned by [?gttrf](#).

Output Parameters

b Overwritten by the solution matrix *x*.

info INTEGER. If *info*=0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gttrs* interface are as follows:

dl Holds the vector of length (*n-1*).

d Holds the vector of length (*n*).

du Holds the vector of length (*n-1*).

du2 Holds the vector of length (*n-2*).

b Holds the matrix *B* of size (*n,nrhs*).

ipiv Holds the vector of length (n).
trans Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|L||U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x) \varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $7n$ (including n divisions) for real flavors and $34n$ (including $2n$ divisions) for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?gtcon](#).

To refine the solution and estimate the error, call [?gtrfs](#).

?potrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call dpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call cpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call zpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call potrs( a, b [,uplo] [, info] )
```

Description

This routine solves for X the system of linear equations $A^*X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$A = U^T * U$ for real data, If $uplo = 'U'$

$A = U^H * U$ for complex

data

$A = L * L^T$ for real data, If $uplo = 'L'$,

$A = L * L^H$ for complex

data

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [?potrf](#) to compute the Cholesky factorization of A .

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates how the input matrix A has been factored:
If $uplo = 'U'$, the upper triangle of A is stored.

	If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a</i> , <i>b</i>	REAL for <i>spotrs</i> DOUBLE PRECISION for <i>dpotrs</i> COMPLEX for <i>cpotrs</i> DOUBLE COMPLEX for <i>zpotrs</i> . Arrays: <i>a</i> (<i>lda</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>a</i> contains the factor <i>U</i> or <i>L</i> (see <i>uplo</i>). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>a</i> must be at least $\max(1, n)$, the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *potrs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If `uplo = 'U'`, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^H||U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for `uplo = 'L'`. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x) \varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$. The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?pocon`.

To refine the solution and estimate the error, call `?porfs`.

?pptrs

Solves a system of linear equations with a packed Cholesky-factored symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spptrs( uplo, n, nrhs, ap, b, ldb, info )
call dpptrs( uplo, n, nrhs, ap, b, ldb, info )
call cpptrs( uplo, n, nrhs, ap, b, ldb, info )
call zpptrs( uplo, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call pptrs( a, b [,uplo] [,info] )
```

Description

This routine solves for x the system of linear equations $A * X = B$ with a packed symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$A = U^T * U$ for real data, If $uplo = 'U'$

$A = U^H * U$ for complex

data

$A = L * L^T$ for real data, If $uplo = 'L'$,

$A = L * L^H$ for complex

data

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [?pptrf](#) to compute the Cholesky factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>ap, b</i>	REAL for <code>spptrs</code> DOUBLE PRECISION for <code>dpptsr</code> COMPLEX for <code>cpptrs</code> DOUBLE COMPLEX for <code>zpptrs</code> . Arrays: $ap(*)$, $b(l\delta b,*)$ The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by $uplo$, in <i>packed storage</i> (see Matrix Storage Schemes).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix x .

$info$ INTEGER. If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptrs` interface are as follows:

a Stands for argument ap in Fortran 77 interface. Holds the array A of size $(n*(n+1)/2)$.
 b Holds the matrix B of size $(n, nrhs)$.
 $uplo$ Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If $uplo = 'U'$, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon \|U^H\| \|U\|$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

A similar estimate holds for $uplo = 'L'$.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x) \epsilon$$

where $\text{cond}(A, x) = \frac{\|A^{-1}\| \|A\| \|x\|}{\|x\|} \leq \|A^{-1}\| \|A\| = \kappa_{\infty}(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_{\infty}(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_{\infty}(A)$, call `?ppcon`.

To refine the solution and estimate the error, call `?pprfs`.

?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call dpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call cpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call zpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call pbtrs( a, b [,uplo] [,info] )
```

Description

This routine solves for real data a system of linear equations $A^*X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite *band* matrix A , given the Cholesky factorization of A :

$A = U^T * U$ for real data, If $uplo = 'U'$

$A = U^H * U$ for complex

data

$A = L * L^T$ for real data, If *uplo* = 'L',

$A = L * L^H$ for complex

data

where *L* is a lower triangular matrix and *U* is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix *B*.

Before calling this routine, you must call [?pbtrf](#) to compute the Cholesky factorization of *A* in the band storage form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the upper triangular factor is stored in <i>ab</i> . If <i>uplo</i> = 'L', the lower triangular factor is stored in <i>ab</i> .
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for <i>spbtrs</i> DOUBLE PRECISION for <i>dpbtrs</i> COMPLEX for <i>cpbtrs</i> DOUBLE COMPLEX for <i>zpbtrs</i> . Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>ab</i> contains the Cholesky factor, as returned by the factorization routine, in <i>band storage</i> form. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>ab</i> must be at least $\max(1, n)$, and the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .

info INTEGER. If *info*=0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbtrs` interface are as follows:

a Stands for argument *ab* in Fortran 77 interface. Holds the array *A* of size $(kd+1, n)$.
b Holds the matrix *B* of size $(n, nrhs)$.
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kd + 1)\varepsilon P|U^H||U| \text{ or } |E| \leq c(kd + 1)\varepsilon P|L^H||L|$$

$c(k)$ is a modest linear function of *k*, and ε is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kd + 1) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector is $4n*kd$ for real flavors and $16n*kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?pbcon](#).

To refine the solution and estimate the error, call [?pbrfs](#).

?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal matrix using the factorization computed by ?pttrf.

Syntax

FORTRAN 77:

```
call spttrs( n, nrhs, d, e, b, ldb, info )
call dpttrs( n, nrhs, d, e, b, ldb, info )
call cpttrs( uplo, n, nrhs, d, e, b, ldb, info )
call zpttrs( uplo, n, nrhs, d, e, b, ldb, info )
```

Fortran 95:

```
call pttrs( d, e, b [,info] )
call pttrs( d, e, b [,uplo] [,info] )
```

Description

This routine solves for X a system of linear equations $A*X = B$ with a symmetric (Hermitian) positive-definite tridiagonal matrix A . Before calling this routine, call [?pttrf](#) to compute the $L*D*L'$ for real data and the $L*D*L'$ or $U'*D*U$ factorization of A for complex data.

Input Parameters

<i>uplo</i>	CHARACTER*1. Used for <code>cpttrs/zpttrs</code> only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>e</i> stores the superdiagonal of A , and A is factored as $U'*D*U$. If <i>uplo</i> = 'L', the array <i>e</i> stores the subdiagonal of A , and A is factored as $L*D*L'$.
<i>n</i>	INTEGER. The order of A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>d</i>	REAL for <code>spttrs, cpttrs</code>

DOUBLE PRECISION for `dpttrs`, `zpttrs`.
 Array, dimension (n). Contains the diagonal elements of the diagonal matrix D from the factorization computed by [?pttrf](#).

`e`, `b` REAL for `spttrs`
 DOUBLE PRECISION for `dpttrs`
 COMPLEX for `cpttrs`
 DOUBLE COMPLEX for `zpttrs`.
 Arrays: `e`($n-1$), `b`(`ldb`, `nrhs`).
 The array `e` contains the ($n-1$) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by [?pttrf](#) (see `uplo`).
 The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations.

`ldb` INTEGER. The leading dimension of `b`; $ldb \geq \max(1, n)$.

Output Parameters

`b` Overwritten by the solution matrix X .

`info` INTEGER. If `info=0`, the execution is successful.
 If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pttrs` interface are as follows:

`d` Holds the vector of length (n).

`e` Holds the vector of length ($n-1$).

`b` Holds the matrix B of size (n , `nrhs`).

`uplo` Used in complex flavors only. Must be 'U' or 'L'. The default value is 'U'.

?sytrs

Solves a system of linear equations with a UDU- or LDL-factored symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call dsytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call csytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call zsytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call sytrs( a, b, ipiv [,uplo] [,info] )
```

Description

This routine solves for x the system of linear equations $A \cdot X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

if $uplo = 'U'$, $A = P \cdot U \cdot D \cdot U^T \cdot P^T$
 if $uplo = 'L'$, $A = P \cdot L \cdot D \cdot L^T \cdot P^T$,

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array $ipiv$ returned by the factorization routine [?sytrf](#).

Input Parameters

$uplo$	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = P \cdot U \cdot D \cdot U^T \cdot P^T$. If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = P \cdot L \cdot D \cdot L^T \cdot P^T$.
n	INTEGER. The order of matrix A ; $n \geq 0$.

<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf .
<i>a, b</i>	REAL for <i>ssytrs</i> DOUBLE PRECISION for <i>dsytrs</i> COMPLEX for <i>csytrs</i> DOUBLE COMPLEX for <i>zsytrs</i> . Arrays: <i>a</i> (<i>lda</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>a</i> contains the factor <i>U</i> or <i>L</i> (see <i>uplo</i>). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the system of equations. The second dimension of <i>a</i> must be at least $\max(1, n)$, and the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sytrs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?sycon](#).

To refine the solution and estimate the error, call [?sytrfs](#).

?hetrs

Solves a system of linear equations with a UDU- or LDL-factored Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call zhetrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call hetrs( a, b, ipiv [, uplo] [,info] )
```

Description

This routine solves for X the system of linear equations $A * X = B$ with a Hermitian matrix A , given the Bunch-Kaufman factorization of A :

if $uplo = 'U'$ $A = P * U * D * U^H * P^T$
 if $uplo = 'L'$ $A = P * L * D * L^H * P^T,$

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array $ipiv$ returned by the factorization routine [?hetrf](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates how the input matrix A has been factored:
 If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = P * U * D * U^H * P^T$.
 If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = P * L * D * L^H * P^T$.

n INTEGER. The order of matrix A ; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

ipiv INTEGER.
 Array, DIMENSION at least $\max(1, n)$.
 The *ipiv* array, as returned by [?hetrf](#).

a, b COMPLEX for *chetrs*
 DOUBLE COMPLEX for *zhetsr*.
 Arrays: $a(lda, *)$, $b(ldb, *)$.
 The array a contains the factor U or L (see *uplo*).
 The array b contains the matrix B whose columns are the right-hand sides for the system of equations.
 The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, nrhs)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrs` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^H|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^H|P^T$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$.

To estimate the condition number $\kappa_{\infty}(A)$, call [?hecon](#).

To refine the solution and estimate the error, call [?herfs](#).

?sptrs

Solves a system of linear equations with a UDU- or LDL-factored symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call dsptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call csptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zsptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call sptrs( a, b, ipiv [, uplo] [,info] )
```

Description

This routine solves for x the system of linear equations $A * X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

if $uplo='U'$, $A = P U D U^T P^T$
 if $uplo='L'$, $A = P L D L^T P^T$,

where P is a permutation matrix, U and L are upper and lower *packed* triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply the factor U (or L) and the array $ipiv$ returned by the factorization routine [?spturf](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates how the input matrix A has been factored:

	If $uplo = 'U'$, the array ap stores the packed factor U of the factorization $A = P*U*D*U^T*P^T$. If $uplo = 'L'$, the array ap stores the packed factor L of the factorization $A = P*L*D*L^T*P^T$.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, n)$. The $ipiv$ array, as returned by ?spturf.
ap, b	REAL for $ssptrs$ DOUBLE PRECISION for $dsptrs$ COMPLEX for $csptrs$ DOUBLE COMPLEX for $zsptrs$. Arrays: $ap(*), b(l, db, *)$. The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L, as specified by $uplo$, in <i>packed storage</i> (see Matrix Storage Schemes). The array b contains the matrix B whose columns are the right-hand sides for the system of equations. The second dimension of b must be at least $\max(1, nrhs)$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b	Overwritten by the solution matrix X .
$info$	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptrs` interface are as follows:

a	Stands for argument ap in Fortran 77 interface. Holds the array A of size $(n*(n+1)/2)$.
b	Holds the matrix B of size $(n, nrhs)$.

ipiv Holds the vector of length (*n*).
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^T|P^T$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \|A^{-1}\|_\infty \|A\|_\infty \|x\|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?spcon](#).

To refine the solution and estimate the error, call [?sprfs](#).

?hptrs

Solves a system of linear equations with a UDU- or LDL-factored Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zhptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call hptrs( a, b, ipiv [,uplo] [,info] )
```

Description

This routine solves for X the system of linear equations $A * X = B$ with a Hermitian matrix A , given the Bunch-Kaufman factorization of A :

if $uplo = 'U'$, $A = P * U * D * U^H * P^T$
 if $uplo = 'L'$, $A = P * L * D * L^H * P^T$,

where P is a permutation matrix, U and L are upper and lower *packed* triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

You must supply to this routine the arrays ap (containing U or L) and $ipiv$ in the form returned by the factorization routine [?hptrf](#).

Input Parameters

$uplo$	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array ap stores the packed factor U of the factorization $A = P * U * D * U^H * P^T$. If $uplo = 'L'$, the array ap stores the packed factor L of the factorization $A = P * L * D * L^H * P^T$.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides; $nrhs \geq 0$.

<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?hptrf</code> .
<i>ap, b</i>	COMPLEX for <code>chptrs</code> DOUBLE COMPLEX for <code>zhptrs</code> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> , *). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the system of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrs` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\epsilon_P |U| |D| |U^H| P^T \text{ or } |E| \leq c(n)\epsilon_P |L| |D| |L^H| P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x) \varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?hpcon](#).

To refine the solution and estimate the error, call [?hprfs](#).

?trtrs

Solves a system of linear equations with a triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call strtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call dtrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call ctrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call ztrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call trtrs( a, b [,uplo] [, trans] [,diag] [,info] )
```

Description

This routine solves for X the following systems of linear equations with a triangular matrix A , with multiple right-hand sides stored in B :

$$\begin{aligned} A * X &= B && \text{if } trans = 'N', \\ A^T * X &= B && \text{if } trans = 'T', \\ A^H * X &= B && \text{if } trans = 'C' \text{ (for complex matrices only).} \end{aligned}$$

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether A is upper or lower triangular:
If *uplo* = 'U', then A is upper triangular.
If *uplo* = 'L', then A is lower triangular.

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
If *trans* = 'N', then $A * X = B$ is solved for X .
If *trans* = 'T', then $A^T * X = B$ is solved for X .
If *trans* = 'C', then $A^H * X = B$ is solved for X .

diag CHARACTER*1. Must be 'N' or 'U'.
If *diag* = 'N', then A is not a unit triangular matrix.
If *diag* = 'U', then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a .

n INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

a, b REAL for strtrs
DOUBLE PRECISION for dtrtrs
COMPLEX for ctrtrs
DOUBLE COMPLEX for ztrtrs.
Arrays: $a(lda,*)$, $b(ldb,*)$.
The array a contains the matrix A .
The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.
The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix *x*.
info INTEGER. If *info*=0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trtrs` interface are as follows:

a Stands for argument *ap* in Fortran 77 interface. Holds the matrix *A* of size $(n * (n+1) / 2)$.
b Holds the matrix *B* of size $(n, nrhs)$.
uplo Must be 'U' or 'L'. The default value is 'U'.
trans Must be 'N', 'C', or 'T'. The default value is 'N'.
diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x) \varepsilon \text{ provided } c(n) \operatorname{cond}(A, x) \varepsilon < 1$$

where $\operatorname{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_{\infty}(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_{\infty}(A)$.

The approximate number of floating-point operations for one right-hand side vector b is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_{\infty}(A)$, call `?trcon`.

To estimate the error in the solution, call `?trrfs`.

?tptrs

Solves a system of linear equations with a packed triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call stptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call dtptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call ctptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call ztptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call tptrs( a, b [,uplo] [, trans] [,diag] [,info] )
```

Description

This routine solves for x the following systems of linear equations with a packed triangular matrix A , with multiple right-hand sides stored in B :

$A * X = B$	if $trans = 'N'$,
$A^T * X = B$	if $trans = 'T'$,
$A^H * X = B$	if $trans = 'C'$ (for complex matrices only).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether A is upper or lower triangular:

	If <i>uplo</i> = 'U', then <i>A</i> is upper triangular. If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', then $A * X = B$ is solved for <i>X</i> . If <i>trans</i> = 'T', then $A^T * X = B$ is solved for <i>X</i> . If <i>trans</i> = 'C', then $A^H * X = B$ is solved for <i>X</i> .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i> .
<i>n</i>	INTEGER. The order of <i>A</i> ; the number of rows in <i>B</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, b</i>	REAL for <i>stptrs</i> DOUBLE PRECISION for <i>dtptrs</i> COMPLEX for <i>ctptrs</i> DOUBLE COMPLEX for <i>ztptrs</i> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the matrix <i>A</i> in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the system of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tpttrs* interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n^*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \operatorname{cond}(A, x) \varepsilon \text{ provided } c(n) \operatorname{cond}(A, x) \varepsilon < 1$$

where $\operatorname{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\operatorname{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector *b* is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tpcon](#).

To estimate the error in the solution, call [?tprfs](#).

?tbtrs

Solves a system of linear equations with a band triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call stbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
call dtbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
call ctbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
call ztbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call tbtrs( a, b [,uplo] [, trans] [,diag] [,info] )
```

Description

This routine solves for X the following systems of linear equations with a band triangular matrix A , with multiple right-hand sides stored in B :

$A * X = B$	if $trans = 'N'$,
$A^T * X = B$	if $trans = 'T'$,
$A^H * X = B$	if $trans = 'C'$ (for complex matrices only).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If $trans = 'N'$, then $A * X = B$ is solved for X . If $trans = 'T'$, then $A^T * X = B$ is solved for X . If $trans = 'C'$, then $A^H * X = B$ is solved for X .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If $diag = 'N'$, then A is not a unit triangular matrix.

If *diag* = 'U', then *A* is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array *ab*.

<i>n</i>	INTEGER. The order of <i>A</i> ; the number of rows in <i>B</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for <i>stbtrs</i> DOUBLE PRECISION for <i>dtbtrs</i> COMPLEX for <i>ctbtrs</i> DOUBLE COMPLEX for <i>ztbtrs</i> . Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>ab</i> contains the matrix <i>A</i> in <i>band storage</i> form. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>ab</i> must be at least $\max(1, n)$, the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tbtrs* interface are as follows:

<i>a</i>	Stands for the argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

trans Must be 'N', 'C', or 'T'. The default value is 'N'.
diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon|A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \|A^{-1}\|_\infty \|A\|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n \times kd$ for real flavors and $8n \times kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tbcon](#).

To estimate the error in the solution, call [?tbrfs](#).

Routines for Estimating the Condition Number

This section describes the LAPACK routines for estimating the *condition number* of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations (see [Error Analysis](#)). Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

?gecon

Estimates the reciprocal of the condition number of a general matrix in the 1-norm or the infinity-norm.

Syntax

FORTRAN 77:

```
call sgecon( norm, n, a, lda, anorm, rcond, work, iwork, info )
call dgecon( norm, n, a, lda, anorm, rcond, work, iwork, info )
call cgecon( norm, n, a, lda, anorm, rcond, work, rwork, info )
call zgecon( norm, n, a, lda, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call gecon( a, anorm, rcond [,norm] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a general matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?getrf](#) to compute the *LU* factorization of A .

Input Parameters

norm CHARACTER*1. Must be '1' or 'O' or 'I'.
 If *norm* = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm.
 If *norm* = 'I', then the routine estimates the condition number of matrix A in infinity-norm.

n INTEGER. The order of the matrix A ; $n \geq 0$.

<i>a, work</i>	REAL for sgecon DOUBLE PRECISION for dgecon COMPLEX for cgecon DOUBLE COMPLEX for zgecon. Arrays: $a(lda, *)$, $work(*)$. The array <i>a</i> contains the <i>LU</i>-factored matrix <i>A</i>, as returned by ?getrf. The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 4*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see Description).
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cgecon DOUBLE PRECISION for zgecon. Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gecon* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .

norm

Must be '1', 'O', or 'I'. The default value is '1'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$ or $A^H*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n^2$ floating-point operations for real flavors and $8*n^2$ for complex flavors.

?gbcon

Estimates the reciprocal of the condition number of a band matrix in the 1-norm or the infinity-norm.

Syntax

FORTRAN 77:

```
call sgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, iwork, info
)
call dgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, iwork, info
)
call cgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, rwork, info
)
call zgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, rwork, info
)
```

Fortran 95:

```
call gbcon( a, ipiv, anorm, rcond [,kl] [,norm] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a general band matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?gbtrf` to compute the *LU* factorization of *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix <i>A</i> in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix <i>A</i> in infinity-norm.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq 2*kl + ku + 1$).
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?gbtrf</code> .
<i>ab, work</i>	REAL for sgbcon DOUBLE PRECISION for dgbcon COMPLEX for cgbcon DOUBLE COMPLEX for zgbcon. Arrays: <i>ab</i>(<i>ldab</i>,*), <i>work</i>(*). The array <i>ab</i> contains the factored band matrix <i>A</i>, as returned by <code>?gbtrf</code>. The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see Description).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cgbcon DOUBLE PRECISION for zgbcon. Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i>=0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbcon* interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(2*k_l + k_u + 1, n)$.
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>kl</i>	If omitted, assumed $k_l = k_u$.
<i>ku</i>	Restored as $k_u = lda - 2*k_l - 1$.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$ or $A^H*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n(k_u + 2k_l)$ floating-point operations for real flavors and $8n(k_u + 2k_l)$ for complex flavors.

?gtcon

Estimates the reciprocal of the condition number of a tridiagonal matrix using the factorization computed by ?gttrf.

Syntax

FORTRAN 77:

```
call sgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, iwork, info
)
call dgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, iwork, info
)
call cgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, info )
call zgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call gtcon( dl, d, du, du2, ipiv, anorm, rcond [,norm] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a real or complex tridiagonal matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty$$

An estimate is obtained for $\|A^{-1}\|$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\| \|A^{-1}\|)$.

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call ?gttrf to compute the *LU* factorization of A .

Input Parameters

norm CHARACTER*1. Must be '1' or 'O' or 'I'.

If $norm = '1'$ or $'O'$, then the routine estimates the condition number of matrix A in 1-norm.

If $norm = 'I'$, then the routine estimates the condition number of matrix A in infinity-norm.

n	INTEGER. The order of the matrix A ; $n \geq 0$.
$dl, d, du, du2$	REAL for sgtcon DOUBLE PRECISION for dgtcon COMPLEX for cgtcon DOUBLE COMPLEX for zgtcon. Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$, $du2(n-2)$. The array dl contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A as computed by ?gttrf. The array d contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A. The array du contains the $(n-1)$ elements of the first superdiagonal of U. The array $du2$ contains the $(n-2)$ elements of the second superdiagonal of U.
$ipiv$	INTEGER. Array, DIMENSION (n). The array of pivot indices, as returned by ?gttrf.
$anorm$	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).
$work$	REAL for sgtcon DOUBLE PRECISION for dgtcon COMPLEX for cgtcon DOUBLE COMPLEX for zgtcon. Workspace array, DIMENSION $(2*n)$.
$iwork$	INTEGER. Workspace array, DIMENSION (n) . Used for real flavors only.

Output Parameters

$rcond$	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond=0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtcon` interface are as follows:

<i>dl</i>	Holds the vector of length ($n-1$).
<i>d</i>	Holds the vector of length (n).
<i>du</i>	Holds the vector of length ($n-1$).
<i>du2</i>	Holds the vector of length ($n-2$).
<i>ipiv</i>	Holds the vector of length (n).
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pocon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spocon( uplo, n, a, lda, anorm, rcond, work, iwork, info )
call dpocon( uplo, n, a, lda, anorm, rcond, work, iwork, info )
call cpocon( uplo, n, a, lda, anorm, rcond, work, rwork, info )
call zpocon( uplo, n, a, lda, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call pocon( a, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?potrf](#) to compute the Cholesky factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for spocon DOUBLE PRECISION for dpocon COMPLEX for cpocon

DOUBLE COMPLEX for `zpocon`.

Arrays: `a(lda,*)`, `work(*)`.

The array `a` contains the factored matrix `A`, as returned by `?potrf`. The second dimension of `a` must be at least $\max(1, n)$.

The array `work` is a workspace for the routine. The dimension of `work` must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

`lda`

INTEGER. The first dimension of `a`; $lda \geq \max(1, n)$.

`anorm`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

The norm of the *original* matrix `A` (see *Description*).

`iwork`

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

`rwork`

REAL for `cpocon`

DOUBLE PRECISION for `zpocon`.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

`rcond`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets `rcond` = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime `rcond` is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

`info`

INTEGER. If `info` = 0, the execution is successful.

If `info` = `-i`, the `i`-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pocon` interface are as follows:

`a`

Holds the matrix `A` of size (n, n) .

`uplo`

Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?ppcon

Estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call sppcon( uplo, n, ap, anorm, rcond, work, iwork, info )
call dppcon( uplo, n, ap, anorm, rcond, work, iwork, info )
call cppcon( uplo, n, ap, anorm, rcond, work, rwork, info )
call zppcon( uplo, n, ap, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call ppcon( a, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A) \text{)}.$$

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?pptrf` to compute the Cholesky factorization of A .

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.

	Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>ap, work</i>	REAL for sppcon DOUBLE PRECISION for dppcon COMPLEX for cppcon DOUBLE COMPLEX for zppcon. Arrays: <i>ap</i> (*), <i>work</i> (*). The array <i>ap</i> contains the packed factored matrix <i>A</i> , as returned by ?pptrf . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cppcon DOUBLE PRECISION for zppcon. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> =0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppcon` interface are as follows:

<code>a</code>	Stands for the argument <code>ap</code> in Fortran 77 interface. Holds the array <code>A</code> of size $(n*(n+1)/2)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed `rcond` is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pbcon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, iwork, info )
call dpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, iwork, info )
call cpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, rwork, info )
call zpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call pbcon( a, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix `A`:

$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1$ (since A is symmetric or Hermitian, $\kappa_\infty(A) = \kappa_1(A)$).

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?pbtrf](#) to compute the Cholesky factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangular factor is stored in <i>ab</i> . If <i>uplo</i> = 'L', the lower triangular factor is stored in <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq kd + 1$).
<i>ab, work</i>	REAL for spbcon DOUBLE PRECISION for dpbcon COMPLEX for cpbcon DOUBLE COMPLEX for zpbcon. Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>work</i> (*). The array <i>ab</i> contains the factored matrix A in band form, as returned by ?pbtrf . The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cpbcon DOUBLE PRECISION for zpbcon. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbcon` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n(kd + 1)$ floating-point operations for real flavors and $16*n(kd + 1)$ for complex flavors.

?ptcon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sptcon( n, d, e, anorm, rcond, work, info )
call dptcon( n, d, e, anorm, rcond, work, info )
call cptcon( n, d, e, anorm, rcond, work, info )
call zptcon( n, d, e, anorm, rcond, work, info )
```

Fortran 95:

```
call ptcon( d, e, anorm, rcond [,info] )
```

Description

This routine computes the reciprocal of the condition number (in the 1-norm) of a real symmetric or complex Hermitian positive-definite tridiagonal matrix using the factorization $A = L * D * L^T$ for real flavors and $A = L * D * L^H$ for complex flavors or $A = U^T * D * U$ for real flavors and $A = U^H * D * U$ for complex flavors computed by [?pttrf](#) :

$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1$ (since A is symmetric or Hermitian, $\kappa_\infty(A) = \kappa_1(A)$).

The norm $\|A^{-1}\|_1$ is computed by a direct method, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute *anorm* as $\|A\|_1 = \max_j \sum_i |a_{ij}|$
- call [?pttrf](#) to compute the factorization of A .

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>d, work</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Arrays, dimension (n).
 The array d contains the n diagonal elements of the diagonal matrix D from the factorization of A , as computed by [?pttrf](#) ;
 $work$ is a workspace array.

e REAL for `sptcon`
 DOUBLE PRECISION for `dptcon`
 COMPLEX for `cptcon`
 DOUBLE COMPLEX for `zptcon`.
 Array, DIMENSION ($n - 1$).
 Contains off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by [?pttrf](#) .

anorm REAL for single precision flavors.
 DOUBLE PRECISION for double precision flavors.
 The 1- norm of the *original* matrix A (see *Description*).

Output Parameters

rcond REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtcon` interface are as follows:

d Holds the vector of length (n).
e Holds the vector of length ($n-1$).

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n(kd + 1)$ floating-point operations for real flavors and $16*n(kd + 1)$ for complex flavors.

?sycon

Estimates the reciprocal of the condition number of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssycon( uplo, n, a, lda, ipiv, anorm, rcond, work, iwork, info )
call dsycon( uplo, n, a, lda, ipiv, anorm, rcond, work, iwork, info )
call csycon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
call zsycon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call sycon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a symmetric matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A) \text{)}.$$

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?sytrf](#) to compute the factorization of A .

Input Parameters

$uplo$ CHARACTER*1. Must be 'U' or 'L'.

Indicates how the input matrix A has been factored:

If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = P*U*D*U^T*P^T$.

If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = P*L*D*L^T*P^T$.

n	INTEGER. The order of matrix A ; $n \geq 0$.
$a, work$	REAL for ssycon DOUBLE PRECISION for dsycon COMPLEX for csycon DOUBLE COMPLEX for zsycon. Arrays: $a(lda, *)$, $work(*)$. The array a contains the factored matrix A , as returned by ?sytrf . The second dimension of a must be at least $\max(1, n)$. The array $work$ is a workspace for the routine. The dimension of $work$ must be at least $\max(1, 2*n)$.
lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array $ipiv$, as returned by ?sytrf .
$anorm$	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).
$iwork$	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

$rcond$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sycon` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A \cdot x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?hecon

Estimates the reciprocal of the condition number of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call checon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
call zhecon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call hecon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a Hermitian matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is Hermitian, } \kappa_\infty(A) = \kappa_1(A) \text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?hetrf` to compute the factorization of *A*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular factor <i>U</i> of the factorization $A = P*U*D*U^H*P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular factor <i>L</i> of the factorization $A = P*L*D*L^H*P^T$.
<i>n</i>	INTEGER. The order of matrix <i>A</i>; $n \geq 0$.
<i>a, work</i>	COMPLEX for <code>checon</code> DOUBLE COMPLEX for <code>zhecon</code>. Arrays: <i>a</i>(<i>lda</i>,*), <i>work</i>(*). The array <i>a</i> contains the factored matrix <i>A</i>, as returned by <code>?hetrf</code>. The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i>, as returned by <code>?hetrf</code>.
<i>anorm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hecon` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A \cdot x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

?spcon

Estimates the reciprocal of the condition number of a packed symmetric matrix.

Syntax

FORTRAN 77:

```
call sspcon( uplo, n, ap, ipiv, anorm, rcond, work, iwork, info )
call dspcon( uplo, n, ap, ipiv, anorm, rcond, work, iwork, info )
call cspcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
call zspcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call spcon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a packed symmetric matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A) \text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?sptfrf` to compute the factorization of *A*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the array <i>ap</i> stores the packed upper triangular factor <i>U</i> of the factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the packed lower triangular factor <i>L</i> of the factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of matrix <i>A</i>; $n \geq 0$.
<i>ap, work</i>	REAL for sspcon DOUBLE PRECISION for dspcon COMPLEX for cspcon DOUBLE COMPLEX for zspcon. Arrays: <i>ap</i>(*), <i>work</i>(*). The array <i>ap</i> contains the packed factored matrix <i>A</i>, as returned by <code>?sptfrf</code>. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i>, as returned by <code>?sptfrf</code>.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spcon` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A * x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?hpcon

Estimates the reciprocal of the condition number of a packed Hermitian matrix.

Syntax

FORTRAN 77:

```
call chpcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
call zhpcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call hpcon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a Hermitian matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is Hermitian, } \kappa_\infty(A) = \kappa_1(A) \text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?hptrf](#) to compute the factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>ap</i> stores the packed upper triangular factor U of the factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the packed lower triangular factor L of the factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>ap, work</i>	COMPLEX for <i>chpcon</i> DOUBLE COMPLEX for <i>zhpcon</i>. Arrays: <i>ap</i>(*), <i>work</i>(*). The array <i>ap</i> contains the packed factored matrix A, as returned by ?hptrf. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i>, as returned by ?hptrf.
<i>anorm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbcon` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>ipiv</i>	Holds the vector of length (<i>n</i>).

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A * x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

?trcon

Estimates the reciprocal of the condition number of a triangular matrix.

Syntax

FORTRAN 77:

```
call strcon( norm, uplo, diag, n, a, lda, rcond, work, iwork, info )
call dtrcon( norm, uplo, diag, n, a, lda, rcond, work, iwork, info )
call ctrcon( norm, uplo, diag, n, a, lda, rcond, work, rwork, info )
call ztrcon( norm, uplo, diag, n, a, lda, rcond, work, rwork, info )
```

Fortran 95:

```
call trcon( a, rcond [,uplo] [,diag] [,norm] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a triangular matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangle of A , other array elements are not referenced. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangle of A , other array elements are not referenced.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.

If *diag* = 'N', then *A* is not a unit triangular matrix.

If *diag* = 'U', then *A* is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array *a*.

n INTEGER. The order of the matrix *A*; $n \geq 0$.

a, work REAL for *strcon*
DOUBLE PRECISION for *dtrcon*
COMPLEX for *ctrcon*
DOUBLE COMPLEX for *ztrcon*.

Arrays: *a(lda,*)*, *work(*)*.

The array *a* contains the matrix *A*. The second dimension of *a* must be at least $\max(1, n)$.

The array *work* is a workspace for the routine. The dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for *ctrcon*
DOUBLE PRECISION for *ztrcon*.
Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond REAL for single precision flavors.
DOUBLE PRECISION for double precision flavors.
An estimate of the reciprocal of the condition number. The routine sets *rcond*=0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trcon` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and $4n^2$ operations for complex flavors.

?tpcon

Estimates the reciprocal of the condition number of a packed triangular matrix.

Syntax

FORTRAN 77:

```
call stpcon( norm, uplo, diag, n, ap, rcond, work, iwork, info )
call dtpcon( norm, uplo, diag, n, ap, rcond, work, iwork, info )
call ctpcon( norm, uplo, diag, n, ap, rcond, work, rwork, info )
call ztpcon( norm, uplo, diag, n, ap, rcond, work, rwork, info )
```

Fortran 95:

```
call tpcon( a, rcond [,uplo] [,diag] [,norm] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a packed triangular matrix *A* in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H) .$$

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix <i>A</i> in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix <i>A</i> in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether <i>A</i> is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of <i>A</i> in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of <i>A</i> in packed form.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>; $n \geq 0$.
<i>ap, work</i>	REAL for stpcon DOUBLE PRECISION for dtpcon COMPLEX for ctpcon DOUBLE COMPLEX for ztpcon. Arrays: <i>ap</i>(*), <i>work</i>(*). The array <i>ap</i> contains the packed matrix <i>A</i>. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for ctpcon DOUBLE PRECISION for ztpcon. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info

INTEGER. If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tpcon` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A * x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and $4n^2$ operations for complex flavors.

?tbcon

Estimates the reciprocal of the condition number of a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, iwork, info )
call dtbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, iwork, info )
call ctbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, rwork, info )
call ztbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, rwork, info )
```

Fortran 95:

```
call tbcon( a, rcond [,uplo] [,diag] [,norm] [,info] )
```

Description

This routine estimates the reciprocal of the condition number of a triangular band matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H) .$$

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of A in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of A in packed form.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.

If *diag* = 'N', then *A* is not a unit triangular matrix.

If *diag* = 'U', then *A* is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array *ab*.

n INTEGER. The order of the matrix *A*; $n \geq 0$.

kd INTEGER. The number of superdiagonals or subdiagonals in the matrix *A*; $kd \geq 0$.

ab, work REAL for stbcon
DOUBLE PRECISION for dtbcon
COMPLEX for ctbcon
DOUBLE COMPLEX for ztbcon.
Arrays: *ab*(*ldab*,*), *work*(*).
The array *ab* contains the band matrix *A*. The second dimension of *ab* must be at least $\max(1, n)$. The array *work* is a workspace for the routine.
The dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldab INTEGER. The first dimension of the array *ab*. ($ldab \geq kd + 1$).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for ctbcon
DOUBLE PRECISION for ztbcon.
Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond REAL for single precision flavors.
DOUBLE PRECISION for double precision flavors.
An estimate of the reciprocal of the condition number. The routine sets *rcond* = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbcon` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n(kd + 1)$ floating-point operations for real flavors and $8*n(kd + 1)$ operations for complex flavors.

Refining the Solution and Estimating Its Error

This section describes the LAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Routines for Solving Systems of Linear Equations](#)).

?gerfs

Refines the solution of a system of linear equations with a general matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call dgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call cgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )

call zgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call gerfs( a, af, ipiv, b, x [,trans] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A * X = B$ or $A^T * X = B$ or $A^H * X = B$ with a general matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?getrf](#)
- call the solver routine [?getrs](#).

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A * X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	REAL for sgerfs DOUBLE PRECISION for dgerfs COMPLEX for cgerfs DOUBLE COMPLEX for zgerfs. Arrays: <i>a</i>(<i>lda</i>,*) contains the original matrix <i>A</i>, as supplied to ?getrf. <i>af</i>(<i>ldaf</i>,*) contains the factored matrix <i>A</i>, as returned by ?getrf. <i>b</i>(<i>ldb</i>,*) contains the right-hand side matrix <i>B</i>. <i>x</i>(<i>ldx</i>,*) contains the solution matrix <i>X</i>. <i>work</i>(*) is a workspace array. The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i>; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i>; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?getrf.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cgerfs DOUBLE PRECISION for zgerfs.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gerfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>af</i>	Holds the matrix <i>AF</i> of size (<i>n</i> , <i>n</i>).
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>x</i>	Holds the matrix <i>X</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward

error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?gbrfs

Refines the solution of a system of linear equations with a general band matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )

call dgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )

call cgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,

```

Fortran 95:

```
call gbrfs( a, af, ipiv, b, x [,kl] [,trans] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?gbtrf](#)

- call the solver routine [?gbtrs](#).

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab,afb,b,x,work</i>	REAL for <i>sgbrfs</i> DOUBLE PRECISION for <i>dgbrfs</i> COMPLEX for <i>cgbrfs</i> DOUBLE COMPLEX for <i>zgbrfs</i>. Arrays: <i>ab</i>(<i>ldab</i>,*) contains the original band matrix <i>A</i>, as supplied to ?gbtrf, but stored in rows from 1 to $kl + ku + 1$. <i>afb</i>(<i>ldaafb</i>,*) contains the factored band matrix <i>A</i>, as returned by ?gbtrf. <i>b</i>(<i>ldb</i>,*) contains the right-hand side matrix <i>B</i>. <i>x</i>(<i>ldx</i>,*) contains the solution matrix <i>X</i>. <i>work</i>(*) is a workspace array. The second dimension of <i>ab</i> and <i>afb</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> .
<i>ldaafb</i>	INTEGER. The first dimension of <i>afb</i> .
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER.

	Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cgbrfs</i> DOUBLE PRECISION for <i>zgbrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbrfs* interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kl+ku+1, n)$.
<i>af</i>	Stands for argument <i>afb</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(2*kl*ku+1, n)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda-kl-1$.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n(k_l + k_u)$ floating-point operations (for real flavors) or $16n(k_l + k_u)$ operations (for complex flavors). In addition, each step of iterative refinement involves $2n(4k_l + 3k_u)$ operations (for real flavors) or $8n(4k_l + 3k_u)$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?gtrfs

Refines the solution of a system of linear equations with a tridiagonal matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )

call dgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )

call cgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, rwork, info )

call zgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gtrfs( dl, d, du, dlf, df, duf, du2, ipiv, b, x [,trans] [,ferr] [,berr]
            [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A * X = B$ or $A^T * X = B$ or $A^H * X = B$ with a tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?gttrf](#)
- call the solver routine [?gttrs](#).

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A * X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>dl,d,du,dlf,</i>	REAL for sgtrfs DOUBLE PRECISION for dgtrfs
<i>df,duf,du2,</i>	COMPLEX for cgtrfs DOUBLE COMPLEX for zgtrfs.
<i>b,x,work</i>	Arrays: <i>dl</i> , dimension $(n - 1)$, contains the subdiagonal elements of A . <i>d</i> , dimension (n) , contains the diagonal elements of A . <i>du</i> , dimension $(n - 1)$, contains the superdiagonal elements of A . <i>dlf</i> , dimension $(n - 1)$, contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A as computed by ?gttrf .

	<i>df</i> , dimension (<i>n</i>), contains the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i> .
	<i>duf</i> , dimension (<i>n</i> - 1), contains the (<i>n</i> - 1) elements of the first superdiagonal of <i>U</i> .
	<i>du2</i> , dimension (<i>n</i> - 2), contains the (<i>n</i> - 2) elements of the second superdiagonal of <i>U</i> .
	<i>b(ldb, nrhs)</i> contains the right-hand side matrix <i>B</i> .
	<i>x(ldx, nrhs)</i> contains the solution matrix <i>X</i> , as computed by ?gttrs .
	<i>work</i> (*) is a workspace array; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gttrf .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). Used for real flavors only.
<i>rwork</i>	REAL for <i>cgtrfs</i> DOUBLE PRECISION for <i>zgtrfs</i> . Workspace array, DIMENSION (<i>n</i>). Used for complex flavors only.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gtrfs* interface are as follows:

<i>dl</i>	Holds the vector of length (<i>n</i> -1).
<i>d</i>	Holds the vector of length (<i>n</i>).
<i>du</i>	Holds the vector of length (<i>n</i> -1).
<i>dlf</i>	Holds the vector of length (<i>n</i> -1).
<i>df</i>	Holds the vector of length (<i>n</i>).
<i>duf</i>	Holds the vector of length (<i>n</i> -1).
<i>du2</i>	Holds the vector of length (<i>n</i> -2).
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>x</i>	Holds the matrix <i>X</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

?porfs

Refines the solution of a system of linear equations with a symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call dporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call cporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, rwork, info )

call zporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, rwork, info )
```

Fortran 95:

```
call porfs( a, af, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?potrf](#)
- call the solver routine [?potrs](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
If *uplo* = 'U', the upper triangle of A is stored.
If *uplo* = 'L', the lower triangle of A is stored.

n INTEGER. The order of the matrix A ; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

a,af,b,x,work REAL for *sporfs*
DOUBLE PRECISION for *dporfs*
COMPLEX for *cporfs*
DOUBLE COMPLEX for *zporfs*.

Arrays:
a(lda,)* contains the original matrix A , as supplied to [?potrf](#).
af(ldaf,)* contains the factored matrix A , as returned by [?potrf](#).
b(ldb,)* contains the right-hand side matrix B .
x(ldx,)* contains the solution matrix X .
work()* is a workspace array.

The second dimension of *a* and *af* must be at least $\max(1, n)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cporfs</i> DOUBLE PRECISION for <i>zporfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *porfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>af</i>	Holds the matrix <i>AF</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?pprfs

Refines the solution of a system of linear equations with a packed symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```
call spprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, iwork,
info )

call dpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, iwork,
info )

call cpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, rwork,
info )

call zpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, rwork,
info )
```

Fortran 95:

```
call pprfs( a, af, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A * X = B$ with a packed symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| / |a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| / |b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pptrf](#)
- call the solver routine [?pptrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, afp, b, x, work</i>	REAL for <i>spprfs</i> DOUBLE PRECISION for <i>dpprfs</i> COMPLEX for <i>cpprfs</i> DOUBLE COMPLEX for <i>zpprfs</i> . Arrays: <i>ap</i> (*) contains the original packed matrix A , as supplied to ?pptrf . <i>afp</i> (*) contains the factored packed matrix A , as returned by ?pptrf . <i>b</i> (ldb, *) contains the right-hand side matrix B . <i>x</i> (ldx, *) contains the solution matrix X . <i>work</i> (*) is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n+1)/2)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ldx INTEGER. The first dimension of *x*; $ldx \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for *cpprfs*
DOUBLE PRECISION for *zpprfs*.
Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x The refined solution matrix *X*.

ferr, berr REAL for single precision flavors.
DOUBLE PRECISION for double precision flavors.
Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info INTEGER. If *info*=0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pprfs* interface are as follows:

a Stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size $(n*(n+1)/2)$.

af Stands for argument *afp* in Fortran 77 interface. Holds the array *AF* of size $(n*(n+1)/2)$.

b Holds the matrix *B* of size $(n, nrhs)$.

x Holds the matrix *X* of size $(n, nrhs)$.

ferr Holds the vector of length $(nrhs)$.

berr Holds the vector of length $(nrhs)$.

`uplo`

Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in `ferr` are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?pbrfs

Refines the solution of a system of linear equations with a band symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

Fortran 77:

```
call spbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call dpbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call cpbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, rwork, info )

call zpbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call pbrfs( a, af, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a symmetric (Hermitian) positive definite band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pbtrf](#)
- call the solver routine [?pbtrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab,afb,b,x,work</i>	REAL for spbrfs DOUBLE PRECISION for dpbrfs COMPLEX for cpbrfs DOUBLE COMPLEX for zpbrfs. Arrays: <i>ab(ldab,*)</i> contains the original band matrix A , as supplied to ?pbtrf . <i>afb(ldafb,*)</i> contains the factored band matrix A , as returned by ?pbtrf . <i>b(l db,*)</i> contains the right-hand side matrix B . <i>x(ldx,*)</i> contains the solution matrix X . <i>work(*)</i> is a workspace array.

The second dimension of *ab* and *afb* must be at least $\max(1, n)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldafb</i>	INTEGER. The first dimension of <i>afb</i> ; $ldafb \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cpbrfs</i> DOUBLE PRECISION for <i>zpbrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pbrfs* interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>af</i>	Stands for argument <i>afb</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.

<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $8n*kd$ floating-point operations (for real flavors) or $32n*kd$ operations (for complex flavors). In addition, each step of iterative refinement involves $12n*kd$ operations (for real flavors) or $48n*kd$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4n*kd$ floating-point operations for real flavors or $16n*kd$ for complex flavors.

?ptrfs

Refines the solution of a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sptrfs( n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work, info )
call dptrfs( n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work, info )
call cptrfs( uplo, n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
call zptrfs( uplo, n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call ptrfs( d, df, e, ef, b, x [,ferr] [,berr] [,info] )
call ptrfs( d, df, e, ef, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A * X = B$ with a symmetric (Hermitian) positive definite tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pttrf](#)
- call the solver routine [?pttrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Used for complex flavors only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>e</i> stores the superdiagonal of A , and A is factored as $U^H * D * U$. If <i>uplo</i> = 'L', the array <i>e</i> stores the subdiagonal of A , and A is factored as $L * D * L^H$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>d, df, rwork</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors Arrays: <i>d</i> (<i>n</i>), <i>df</i> (<i>n</i>), <i>rwork</i> (<i>n</i>). The array <i>d</i> contains the <i>n</i> diagonal elements of the tridiagonal matrix A . The array <i>df</i> contains the <i>n</i> diagonal elements of the diagonal matrix D from the factorization of A as computed by ?pttrf . The array <i>rwork</i> is a workspace array used for complex flavors only.
<i>e, ef, b, x, work</i>	REAL for <i>spttrs</i> DOUBLE PRECISION for <i>dpttrs</i>

COMPLEX for `cptrfs`

DOUBLE COMPLEX for `zptrfs`.

Arrays: `e(n-1)`, `ef(n-1)`, `b(ldb,nrhs)`, `x(ldx,nrhs)`, `work(*)`.

The array `e` contains the $(n-1)$ off-diagonal elements of the tridiagonal matrix A (see `uplo`).

The array `ef` contains the $(n-1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by `?pttrf` (see `uplo`).

The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations.

The array `x` contains the solution matrix X as computed by `?pttrs`.

The array `work` is a workspace array. The dimension of `work` must be at least $2*n$ for real flavors, and at least n for complex flavors.

`ldb` INTEGER. The leading dimension of `b`; $ldb \geq \max(1, n)$.

`ldx` INTEGER. The leading dimension of `x`; $ldx \geq \max(1, n)$.

Output Parameters

`x` The refined solution matrix X .

`ferr, berr` REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

`info` INTEGER.

If `info` = 0, the execution is successful.

If `info` = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptrfs` interface are as follows:

`d` Holds the vector of length (n) .

`df` Holds the vector of length (n) .

`e` Holds the vector of length $(n-1)$.

<i>ef</i>	Holds the vector of length (<i>n</i> -1).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>x</i>	Holds the matrix <i>X</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>uplo</i>	Used in complex flavors only. Must be 'U' or 'L'. The default value is 'U'.

?syrrfs

Refines the solution of a system of linear equations with a symmetric matrix and estimates its error.

Syntax

Fortran 77:

```
call ssyrrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call dsyrrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call csyrrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )

call zsyrrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call syrrfs( a, af, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric full-storage matrix *A*, with multiple right-hand sides. For each computed solution vector *x*, the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of *A* and *b* such that *x* is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine `?sytrf`
- call the solver routine `?sytrs`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , the upper triangle of A is stored. If <code>uplo = 'L'</code> , the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<code>a, af, b, x, work</code>	REAL for <code>ssyrfs</code> DOUBLE PRECISION for <code>dsyrfs</code> COMPLEX for <code>csyrfs</code> DOUBLE COMPLEX for <code>zsyrfs</code> . Arrays: <code>a(lda, *)</code> contains the original matrix A , as supplied to <code>?sytrf</code> . <code>af(ldaf, *)</code> contains the factored matrix A , as returned by <code>?sytrf</code> . <code>b(ldb, *)</code> contains the right-hand side matrix B . <code>x(ldx, *)</code> contains the solution matrix X . <code>work(*)</code> is a workspace array. The second dimension of <code>a</code> and <code>af</code> must be at least $\max(1, n)$; the second dimension of <code>b</code> and <code>x</code> must be at least $\max(1, nrhs)$; the dimension of <code>work</code> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<code>lda</code>	INTEGER. The first dimension of <code>a</code> ; $lda \geq \max(1, n)$.
<code>ldaf</code>	INTEGER. The first dimension of <code>af</code> ; $ldaf \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The first dimension of <code>b</code> ; $ldb \geq \max(1, n)$.
<code>ldx</code>	INTEGER. The first dimension of <code>x</code> ; $ldx \geq \max(1, n)$.
<code>ipiv</code>	INTEGER.

	Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>csyrfs</i> DOUBLE PRECISION for <i>zsyrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syrfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>af</i>	Holds the matrix <i>AF</i> of size (n, n) .
<i>ipiv</i>	Holds the vector of length (n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?herfs

Refines the solution of a system of linear equations with a complex Hermitian matrix and estimates its error.

Syntax

FORTRAN 77:

```
call cherfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )

call zherfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call herfs( a, af, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a complex Hermitian full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?hetrf](#)

- call the solver routine [?hetrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	COMPLEX for cherfs DOUBLE COMPLEX for zherfs. Arrays: <i>a(lda,*)</i> contains the original matrix <i>A</i> , as supplied to ?hetrf . <i>af(ldaf,*)</i> contains the factored matrix <i>A</i> , as returned by ?hetrf . <i>b(ldb,*)</i> contains the right-hand side matrix <i>B</i> . <i>x(ldx,*)</i> contains the solution matrix <i>X</i> . <i>work(*)</i> is a workspace array. The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hetrf .
<i>rwork</i>	REAL for cherfs DOUBLE PRECISION for zherfs. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for cherfs

DOUBLE PRECISION for `zherfs`.
 Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sprfs` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>af</i>	Stands for argument <i>afp</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(n * (n+1) / 2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A * X = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?hprfs

Refines the solution of a system of linear equations with a packed complex Hermitian matrix and estimates the solution error.

Syntax

FORTRAN 77:

```
call chprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )

call zhprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call hprfs( a, af, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a packed complex Hermitian matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?hptrf](#)
- call the solver routine [?hptrs](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', the upper triangle of A is stored.
 If *uplo* = 'L', the lower triangle of A is stored.

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap,afp,b,x,work</i>	COMPLEX for <code>chprfs</code> DOUBLE COMPLEX for <code>zhprfs</code> . Arrays: <i>ap</i> (*) contains the original packed matrix <i>A</i> , as supplied to ?hptrf . <i>afp</i> (*) contains the factored packed matrix <i>A</i> , as returned by ?hptrf . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix <i>B</i> . <i>x</i> (<i>ldx</i> ,*) contains the solution matrix <i>X</i> . <i>work</i> (*) is a workspace array. The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hptrf .
<i>rwork</i>	REAL for <code>chprfs</code> DOUBLE PRECISION for <code>zhprfs</code> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr,berr</i>	REAL for <code>chprfs</code> . DOUBLE PRECISION for <code>zhprfs</code> . Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hprfs` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n^* (n+1) / 2)$.
<i>af</i>	Stands for argument <i>afp</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(n^* (n+1) / 2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ operations. In addition, each step of iterative refinement involves $24n^2$ operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A^*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

The real counterpart of this routine is [?ssprfs/?dsprfs](#).

?trrfs

Estimates the error in the solution of a system of linear equations with a triangular matrix.

Syntax

FORTRAN 77:

```
call strrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call dtrrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call ctrrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, rwork, info )

call ztrrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, rwork, info )
```

Fortran 95:

```
call trrfs( a, b, x [,uplo] [,trans] [,diag] [,ferr] [,berr] [,info] )
```

Description

This routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?trtrs](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether A is upper or lower triangular:
If *uplo* = 'U', then A is upper triangular.

If *uplo* = 'L', then *A* is lower triangular.

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If *trans* = 'N', the system has the form $A * X = B$.
If *trans* = 'T', the system has the form $A^T * X = B$.
If *trans* = 'C', the system has the form $A^H * X = B$.

diag CHARACTER*1. Must be 'N' or 'U'.
If *diag* = 'N', then *A* is not a unit triangular matrix.
If *diag* = 'U', then *A* is unit triangular: diagonal elements of *A* are assumed to be 1 and not referenced in the array *a*.

n INTEGER. The order of the matrix *A*; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

a, *b*, *x*, *work* REAL for *strrfs*
DOUBLE PRECISION for *dtrrfs*
COMPLEX for *ctrfrs*
DOUBLE COMPLEX for *ztrrfs*.
Arrays:
a(*lda*,*) contains the upper or lower triangular matrix *A*, as specified by *uplo*.
b(*ldb*,*) contains the right-hand side matrix *B*.
x(*ldx*,*) contains the solution matrix *X*.
work(*) is a workspace array.
The second dimension of *a* must be at least $\max(1, n)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ldx INTEGER. The first dimension of *x*; $ldx \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for *ctrfrs*
DOUBLE PRECISION for *ztrrfs*.
Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trrfs` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A^*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

?tprfs

Estimates the error in the solution of a system of linear equations with a packed triangular matrix.

Syntax

FORTRAN 77:

```
call stprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            iwork, info )
call dtprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            iwork, info )
call ctprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
call ztprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call tprfs( a, b, x [,uplo] [,trans] [,diag] [,ferr] [,berr] [,info] )
```

Description

This routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a packed triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}|/|a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i|/|b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?tpttrs](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates whether A is upper or lower triangular:
 If *uplo* = 'U', then A is upper triangular.

	If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T X = B$. If <i>trans</i> = 'C', the system has the form $A^H X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', <i>A</i> is unit triangular: diagonal elements of <i>A</i> are assumed to be 1 and not referenced in the array <i>ap</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, b, x, work</i>	REAL for <i>stprfs</i> DOUBLE PRECISION for <i>dtprfs</i> COMPLEX for <i>ctprfs</i> DOUBLE COMPLEX for <i>ztpfrfs</i>. Arrays: <i>ap</i>(*) contains the upper or lower triangular matrix <i>A</i>, as specified by <i>uplo</i>. <i>b</i>(<i>ldb</i>,*) contains the right-hand side matrix <i>B</i>. <i>x</i>(<i>ldx</i>,*) contains the solution matrix <i>X</i>. <i>work</i>(*) is a workspace array. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i>; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctprfs</i> DOUBLE PRECISION for <i>ztpfrfs</i>. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tprfs` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A * x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

?tbrfs

Estimates the error in the solution of a system of linear equations with a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call dtbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, iwork, info )

call ctbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, rwork, info )

call ztbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call tbrfs( a, b, x [,uplo] [,trans] [,diag] [,ferr] [,berr] [,info] )
```

Description

This routine estimates the errors in the solution to a system of linear equations $A * X = B$ or $A^T * X = B$ or $A^H * X = B$ with a triangular band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| / |a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| / |b_i| \leq \beta |b_i| \text{ such that } (A + \delta A) x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?tbtrs](#).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether A is upper or lower triangular:
If *uplo* = 'U', then A is upper triangular.

	If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', <i>A</i> is unit triangular: diagonal elements of <i>A</i> are assumed to be 1 and not referenced in the array <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals or sub-diagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b, x, work</i>	REAL for stbrfs DOUBLE PRECISION for dtbrfs COMPLEX for ctbrfs DOUBLE COMPLEX for ztbrfs. Arrays: <i>ab(ldab,*)</i> contains the upper or lower triangular matrix <i>A</i> , as specified by <i>uplo</i> , in band storage format. <i>b(l db,*)</i> contains the right-hand side matrix <i>B</i> . <i>x(ldx,*)</i> contains the solution matrix <i>X</i> . <i>work(*)</i> is a workspace array. The second dimension of <i>a</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for ctbrfs DOUBLE PRECISION for ztbrfs.

Workspace array, `DIMENSION` at least $\max(1, n)$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, <code>DIMENSION</code> at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbrfs` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n*kd$ floating-point operations for real flavors or $8n*kd$ operations for complex flavors.

Routines for Matrix Inversion

It is seldom necessary to compute an explicit inverse of a matrix. In particular, do not attempt to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Routines for Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

However, matrix inversion routines are provided for the rare occasions when an explicit inverse matrix is needed.

?getri

Computes the inverse of an LU-factored general matrix.

Syntax

FORTRAN 77:

```
call sgetri( n, a, lda, ipiv, work, lwork, info )
call dgetri( n, a, lda, ipiv, work, lwork, info )
call cgetri( n, a, lda, ipiv, work, lwork, info )
call zgetri( n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call getri( a, ipiv [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a general matrix A . Before calling this routine, call [?getrf](#) to factorize A .

Input Parameters

n	INTEGER. The order of the matrix A ; $n \geq 0$.
$a, work$	REAL for sgetri DOUBLE PRECISION for dgetri COMPLEX for cgetri DOUBLE COMPLEX for zgetri.

Arrays: $a(lda, *)$, $work(*)$.
 $a(lda, *)$ contains the factorization of the matrix A , as returned by [?getrf](#): $A = P * L * U$.
The second dimension of a must be at least $\max(1, n)$.
 $work(*)$ is a workspace array of dimension at least $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$.
The *ipiv* array, as returned by [?getrf](#).

lwork INTEGER. The size of the *work* array; $lwork \geq n$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.

See *Application Notes* below for the suggested value of *lwork*.

Output Parameters

a Overwritten by the n -by- n matrix $\text{inv}(A)$.

work(1) If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER. If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, the i -th diagonal element of the factor U is zero, U is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getri` interface are as follows:

a Holds the matrix A of size (n, n) .
ipiv Holds the vector of length (n) .

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed inverse X satisfies the following error bound:

$$\|XA - I\| \leq c(n)\epsilon\|X\|P\|L\|\|U\|,$$

where $c(n)$ is a modest linear function of n ; ϵ is the machine precision; I denotes the identity matrix; P , L , and U are the factors of the matrix factorization $A = P * L * U$.

The total number of floating-point operations is approximately $(4/3)n^3$ for real flavors and $(16/3)n^3$ for complex flavors.

?potri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotri( uplo, n, a, lda, info )
call dpotri( uplo, n, a, lda, info )
call cpotri( uplo, n, a, lda, info )
call zpotri( uplo, n, a, lda, info )
```

Fortran 95:

```
call potri( a [,uplo] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A . Before calling this routine, call [?potrf](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for spotri DOUBLE PRECISION for dpotri COMPLEX for cpotri DOUBLE COMPLEX for zpotri. Array $a(lda, *)$. Contains the factorization of the matrix A , as returned by ?potrf . The second dimension of a must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

Output Parameters

a Overwritten by the n -by- n matrix `inv(A)`.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `potri` interface are as follows:

a Holds the matrix *A* of size (n, n) .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n)\varepsilon\kappa_2(A), \quad \|AX - I\|_2 \leq c(n)\varepsilon\kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ε is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix *A* is defined by $\|A\|_2 = \max_{x \cdot x=1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?pptri

Computes the inverse of a packed symmetric (Hermitian) positive-definite matrix

Syntax

FORTRAN 77:

```
call spptri( uplo, n, ap, info )
call dpptri( uplo, n, ap, info )
call cpptri( uplo, n, ap, info )
call zpptri( uplo, n, ap, info )
```

Fortran 95:

```
call pptri( a [,uplo] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A in *packed* form. Before calling this routine, call [?pptrf](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular factor is stored in <i>ap</i> : If <i>uplo</i> = 'U', then the upper triangular factor is stored. If <i>uplo</i> = 'L', then the lower triangular factor is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>ap</i>	REAL for spptri DOUBLE PRECISION for dpptri COMPLEX for cpptri DOUBLE COMPLEX for zpptri. Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains the factorization of the packed matrix A , as returned by ?pptrf . The dimension <i>ap</i> must be at least $\max(1, n(n+1)/2)$.

Output Parameters

ap Overwritten by the packed n -by- n matrix $\text{inv}(A)$.

info INTEGER.
 If $\text{info} = 0$, the execution is successful.
 If $\text{info} = -i$, the i -th parameter had an illegal value.
 If $\text{info} = i$, the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptri` interface are as follows:

a Stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size $(n*(n+1)/2)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n)\varepsilon\kappa_2(A), \quad \|AX - I\|_2 \leq c(n)\varepsilon\kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ε is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix A is defined by $\|A\|_2 = \max_{x \cdot x=1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?sytri

Computes the inverse of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytri( uplo, n, a, lda, ipiv, work, info )
call dsytri( uplo, n, a, lda, ipiv, work, info )
call csytri( uplo, n, a, lda, ipiv, work, info )
call zsytri( uplo, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call sytri( a, ipiv [,uplo] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a symmetric matrix A . Before calling this routine, call [?sytrf](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the Bunch-Kaufman factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the Bunch-Kaufman factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of the matrix A; $n \geq 0$.
<i>a, work</i>	REAL for ssytri DOUBLE PRECISION for dsytri COMPLEX for csytri DOUBLE COMPLEX for zsytri. Arrays: <i>a</i>(<i>lda</i>,*) contains the factorization of the matrix A, as returned by ?sytrf. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array.

The dimension of *work* must be at least $\max(1, 2*n)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$.
The *ipiv* array, as returned by [?sytrf](#).

Output Parameters

a Overwritten by the n -by- n matrix $\text{inv}(A)$.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, the *i*-th diagonal element of *D* is zero, *D* is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytri` interface are as follows:

a Holds the matrix *A* of size (n, n) .

ipiv Holds the vector of length (n) .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse *x* satisfies the following error bounds:

$$|D*U^T*P^T*X*P*U - I| \leq c(n)\epsilon(|D||U^T|P^T|X|P|U| + |D||D^{-1}|)$$

for *uplo* = 'U', and

$$|D*L^T*P^T*X*P*L - I| \leq c(n)\epsilon(|D||L^T|P^T|X|P|L| + |D||D^{-1}|)$$

for *uplo* = 'L'. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; *I* denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?hetri

Computes the inverse of a complex Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetri( uplo, n, a, lda, ipiv, work, info )
call zhetri( uplo, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call hetri( a, ipiv [,uplo] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a complex Hermitian matrix A . Before calling this routine, call [?hetrf](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the Bunch-Kaufman factorization $A = P*U*D*U^H*P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the Bunch-Kaufman factorization $A = P*L*D*L^H*P^T$.
<i>n</i>	INTEGER. The order of the matrix A; $n \geq 0$.
<i>a, work</i>	COMPLEX for <code>chetri</code> DOUBLE COMPLEX for <code>zhetri</code>. Arrays: <i>a</i>(<i>lda</i>,*) contains the factorization of the matrix A, as returned by ?hetrf. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER.

Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?hetrf](#).

Output Parameters

a Overwritten by the n -by- n matrix $\text{inv}(A)$.
info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of *D* is zero, *D* is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetri` interface are as follows:

a Holds the matrix *A* of size (n, n) .
ipiv Holds the vector of length (n) .
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|D^*U^H P^T X P U - I| \leq c(n)\epsilon(|D||U^H|P^T|X|P|U| + |D||D^{-1}|)$$

for *uplo* = 'U', and

$$|D^*L^H P^T X P L - I| \leq c(n)\epsilon(|D||L^H|P^T|X|P|L| + |D||D^{-1}|)$$

for *uplo* = 'L'. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

The real counterpart of this routine is [?sytri](#).

?sptri

Computes the inverse of a symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptri( uplo, n, ap, ipiv, work, info )
call dsptri( uplo, n, ap, ipiv, work, info )
call csptri( uplo, n, ap, ipiv, work, info )
call zsptri( uplo, n, ap, ipiv, work, info )
```

Fortran 95:

```
call sptri( a, ipiv [,uplo] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a packed symmetric matrix A . Before calling this routine, call [?sptrf](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>ap</i> stores the Bunch-Kaufman factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the Bunch-Kaufman factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of the matrix A; $n \geq 0$.
<i>ap, work</i>	REAL for ssptri DOUBLE PRECISION for dsptri COMPLEX for csptri DOUBLE COMPLEX for zsptri. Arrays: <i>ap</i>(*) contains the factorization of the matrix A, as returned by ?sptrf. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. <i>work</i>(*) is a workspace array.

The dimension of *work* must be at least $\max(1, n)$.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?spturf](#).

Output Parameters

ap Overwritten by the n -by- n matrix $\text{inv}(A)$ in packed form.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, the *i*-th diagonal element of *D* is zero, *D* is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spturi* interface are as follows:

a Stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size $(n * (n+1) / 2)$.

ipiv Holds the vector of length (*n*).

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse *x* satisfies the following error bounds:

$$|D * U^T * P^T * X * P * U - I| \leq c(n) \epsilon (|D| |U^T| P^T |X| P |U| + |D| |D^{-1}|)$$

for *uplo* = 'U', and

$$|D * L^T * P^T * X * P * L - I| \leq c(n) \epsilon (|D| |L^T| P^T |X| P |L| + |D| |D^{-1}|)$$

for *uplo* = 'L'. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; *I* denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3) n^3$ for real flavors and $(8/3) n^3$ for complex flavors.

?hptri

Computes the inverse of a complex Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptri( uplo, n, ap, ipiv, work, info )
call zhptri( uplo, n, ap, ipiv, work, info )
```

Fortran 95:

```
call hptri( a, ipiv [,uplo] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a complex Hermitian matrix A using packed storage. Before calling this routine, call [?hptrf](#) to factorize A .

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo</code> = 'U', the array <code>ap</code> stores the packed Bunch-Kaufman factorization $A = P*U*D*U^H*P^T$. If <code>uplo</code> = 'L', the array <code>ap</code> stores the packed Bunch-Kaufman factorization $A = P*L*D*L^H*P^T$.
<code>n</code>	INTEGER. The order of the matrix A; $n \geq 0$.
<code>ap, work</code>	COMPLEX for <code>chptri</code> DOUBLE COMPLEX for <code>zhptri</code>. Arrays: <code>ap(*)</code> contains the factorization of the matrix A, as returned by ?hptrf. The dimension of <code>ap</code> must be at least $\max(1, n(n+1)/2)$. <code>work(*)</code> is a workspace array. The dimension of <code>work</code> must be at least $\max(1, n)$.
<code>ipiv</code>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <code>ipiv</code> array, as returned by ?hptrf.

Output Parameters

<i>ap</i>	Overwritten by the n -by- n matrix <code>inv(A)</code> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <i>D</i> is zero, <i>D</i> is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptri` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>ipiv</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse *X* satisfies the following error bounds:

$$|D^*U^H P^T X^* P^* U - I| \leq c(n) \varepsilon (|D| |U^H| P^T |X| P |U| + |D| |D^{-1}|)$$

for *uplo* = 'U', and

$$|D^* L^H P^T X^* P L - I| \leq c(n) \varepsilon (|D| |L^H| P^T |X| P |L| + |D| |D^{-1}|)$$

for *uplo* = 'L'. Here $c(n)$ is a modest linear function of n , and ε is the machine precision; *I* denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3) n^3$ for real flavors and $(8/3) n^3$ for complex flavors.

The real counterpart of this routine is [?sptri](#).

ztrtri

Computes the inverse of a triangular matrix.

Syntax

FORTRAN 77:

```
call strtri( uplo, diag, n, a, lda, info )
call dtrtri( uplo, diag, n, a, lda, info )
call ctrtri( uplo, diag, n, a, lda, info )
call ztrtri( uplo, diag, n, a, lda, info )
```

Fortran 95:

```
call trtri( a [,uplo] [,diag] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a triangular matrix A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a.
<i>n</i>	INTEGER. The order of the matrix A; $n \geq 0$.
<i>a</i>	REAL for strtri DOUBLE PRECISION for dtrtri COMPLEX for ctrtri DOUBLE COMPLEX for ztrtri. Array: DIMENSION (, *). Contains the matrix A. The second dimension of a must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

Output Parameters

a Overwritten by the n -by- n matrix $\text{inv}(A)$.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of *A* is zero, *A* is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trtri` interface are as follows:

a Holds the matrix *A* of size (n, n) .

uplo Must be 'U' or 'L'. The default value is 'U'.

diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$\|XA - I\| \leq c(n)\varepsilon \|X\| \|A\|$$

$$\|XA - I\| \leq c(n)\varepsilon \|A^{-1}\| \|A\| \|X\|,$$

where $c(n)$ is a modest linear function of n ; ε is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

?tptri

Computes the inverse of a triangular matrix using packed storage.

Syntax

FORTRAN 77:

```
call stptri( uplo, diag, n, ap, info )
call dtptri( uplo, diag, n, ap, info )
call ctptri( uplo, diag, n, ap, info )
call ztptri( uplo, diag, n, ap, info )
```

Fortran 95:

```
call tptri( a [,uplo] [,diag] [,info] )
```

Description

This routine computes the inverse $\text{inv}(A)$ of a packed triangular matrix A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>ap</i>.
<i>n</i>	INTEGER. The order of the matrix A; $n \geq 0$.
<i>ap</i>	REAL for stptri DOUBLE PRECISION for dtptri COMPLEX for ctptri DOUBLE COMPLEX for ztptri. Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains the packed triangular matrix A.

Output Parameters

ap Overwritten by the packed n -by- n matrix $\text{inv}(A)$.

info INTEGER.
 If $\text{info} = 0$, the execution is successful.
 If $\text{info} = -i$, the i -th parameter had an illegal value.
 If $\text{info} = i$, the i -th diagonal element of A is zero, A is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tptri` interface are as follows:

a Stands for argument *ap* in Fortran 77 interface. Holds the array A of size $(n*(n+1)/2)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|XA - I| \leq c(n)\epsilon |X| |A|$$

$$|X - A^{-1}| \leq c(n)\epsilon |A^{-1}| |A| |X|,$$

where $c(n)$ is a modest linear function of n ; ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

Routines for Matrix Equilibration

Routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

?geequ

Computes row and column scaling factors intended to equilibrate a matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call dgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call cgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call zgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
```

Fortran 95:

```
call geequ( a, r, c [,rowcnd] [,colcnd] [,amax] [,info] )
```

Description

This routine computes row and column scalings intended to equilibrate an m -by- n matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

See [?laqge](#) auxiliary function that uses scaling factors computed by [?geequ](#).

Input Parameters

m	INTEGER. The number of rows of the matrix A ; $m \geq 0$.
n	INTEGER. The number of columns of the matrix A ; $n \geq 0$.
a	REAL for sgeequ DOUBLE PRECISION for dgeequ COMPLEX for cgeequ DOUBLE COMPLEX for zgeequ . Array: DIMENSION ($lda, *$). Contains the m -by- n matrix A whose equilibration factors are to be computed. The second dimension of a must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of *a*; $lda \geq \max(1, m)$.

Output Parameters

r, c REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Arrays: $r(m)$, $c(n)$.
If $info = 0$, or $info > m$, the array *r* contains the row scale factors of the matrix *A*.
If $info = 0$, the array *c* contains the column scale factors of the matrix *A*.

rowcnd REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
If $info = 0$ or $info > m$, *rowcnd* contains the ratio of the smallest $r(i)$ to the largest $r(i)$.

colcnd REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
If $info = 0$, *colcnd* contains the ratio of the smallest $c(i)$ to the largest $c(i)$.

amax REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Absolute value of the largest element of the matrix *A*.

info INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the *i*-th parameter had an illegal value.
If $info = i$ and
 $i \leq m$, the *i*-th row of *A* is exactly zero;
 $i > m$, the $(i-m)$ th column of *A* is exactly zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geequ` interface are as follows:

a Holds the matrix *A* of size (m, n) .
r Holds the vector of length (m) .

c Holds the vector of length (*n*).

Application Notes

All the components of *r* and *c* are restricted to be between SMLNUM = smallest safe number and BIGNUM= largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of *A* but works well in practice.

If *rowcnd* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *r*.

If *colcnd* ≥ 0.1 , it is not worth scaling by *c*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?gbequ

Computes row and column scaling factors intended to equilibrate a band matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call dgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call cgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call zgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
```

Fortran 95:

```
call gbequ( a, r, c [,kl] [,rowcnd] [,colcnd] [,amax] [,info] )
```

Description

This routine computes row and column scalings intended to equilibrate an *m*-by-*n* band matrix *A* and reduce its condition number. The output array *r* returns the row scale factors and the array *c* the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix *B* with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

See ?laqgb auxiliary function that uses scaling factors computed by ?gbequ.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ; $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>ab</i>	REAL for sgbequ DOUBLE PRECISION for dgbequ COMPLEX for cgbequ DOUBLE COMPLEX for zgbequ. Array, DIMENSION (<i>ldab</i> , *). Contains the original band matrix <i>A</i> stored in rows from 1 to $kl + ku + 1$. The second dimension of <i>ab</i> must be at least $\max(1, n)$;
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; $ldab \geq kl + ku + 1$.

Output Parameters

<i>r</i> , <i>c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>r</i> (<i>m</i>), <i>c</i> (<i>n</i>). If <i>info</i> = 0, or <i>info</i> > <i>m</i> , the array <i>r</i> contains the row scale factors of the matrix <i>A</i> . If <i>info</i> = 0, the array <i>c</i> contains the column scale factors of the matrix <i>A</i> .
<i>rowcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0 or <i>info</i> > <i>m</i> , <i>rowcnd</i> contains the ratio of the smallest <i>r</i> (<i>i</i>) to the largest <i>r</i> (<i>i</i>).
<i>colcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>colcnd</i> contains the ratio of the smallest <i>c</i> (<i>i</i>) to the largest <i>c</i> (<i>i</i>).
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

info Absolute value of the largest element of the matrix *A*.
 INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i* and
 i ≤ *m*, the *i*-th row of *A* is exactly zero;
 i > *m*, the (*i*-*m*)th column of *A* is exactly zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbequ` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size (<i>kl</i> + <i>ku</i> +1, <i>n</i>).
<i>r</i>	Holds the vector of length (<i>m</i>).
<i>c</i>	Holds the vector of length (<i>n</i>).
<i>kl</i>	If omitted, assumed <i>kl</i> = <i>ku</i> .
<i>ku</i>	Restored as <i>ku</i> = <i>lda</i> - <i>kl</i> -1.

Application Notes

All the components of *r* and *c* are restricted to be between SMLNUM = smallest safe number and BIGNUM= largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of *A* but works well in practice.

If *rowcnd* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *r*.

If *colcnd* ≥ 0.1, it is not worth scaling by *c*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spoequ( n, a, lda, s, scond, amax, info )
call dpoequ( n, a, lda, s, scond, amax, info )
call cpoequ( n, a, lda, s, scond, amax, info )
call zpoequ( n, a, lda, s, scond, amax, info )
```

Fortran 95:

```
call poequ( a, s [,scond] [,amax] [,info] )
```

Description

This routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix A and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See [?laqsy](#) auxiliary function that uses scaling factors computed by [?poequ](#).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i>	REAL for spoequ DOUBLE PRECISION for dpoequ COMPLEX for cpoequ DOUBLE COMPLEX for zpoequ. Array: DIMENSION (<i>lda</i> , *). Contains the <i>n</i> -by- <i>n</i> symmetric or Hermitian positive definite matrix <i>A</i> whose scaling factors are to be computed. Only diagonal elements of <i>A</i> are referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> .
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>).
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <i>A</i> is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `poequ` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>s</i>	Holds the vector of length (n) .

Application Notes

If $scond \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by s .

If $amax$ is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?ppequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix in packed storage and reduce its condition number.

Syntax

FORTRAN 77:

```
call sppequ( uplo, n, ap, s, scond, amax, info )
call dppequ( uplo, n, ap, s, scond, amax, info )
call cppequ( uplo, n, ap, s, scond, amax, info )
call zppequ( uplo, n, ap, s, scond, amax, info )
```

Fortran 95:

```
call ppequ( a, s [,scond] [,amax] [,uplo] [,info] )
```

Description

This routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix *A* in packed storage and reduce its condition number (with respect to the two-norm). The output array *s* returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See [?laqsp](#) auxiliary function that uses scaling factors computed by [?ppequ](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is packed in the array <i>ap</i>: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the matrix A. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the matrix A.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>ap</i>	REAL for sppequ DOUBLE PRECISION for dppequ COMPLEX for cppequ DOUBLE COMPLEX for zppequ. Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the upper or the lower triangular part of the matrix A (as specified by <i>uplo</i>) in <i>packed storage</i> (see Matrix Storage Schemes).

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (n). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for A.
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest $s(i)$ to the largest $s(i)$.
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix A.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of *A* is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppequ` interface are as follows:

a Stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size $(n * (n+1) / 2)$.
s Holds the vector of length (*n*).
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If *scond* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *s*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?pbequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive-definite band matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spbequ( uplo, n, kd, ab, ldab, s, acond, amax, info )
call dpbequ( uplo, n, kd, ab, ldab, s, acond, amax, info )
call cpbequ( uplo, n, kd, ab, ldab, s, acond, amax, info )
call zpbequ( uplo, n, kd, ab, ldab, s, acond, amax, info )
```

Fortran 95:

```
call pbequ( a, s [,scond] [,amax] [,uplo] [,info] )
```

Description

This routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix *A* in packed storage and reduce its condition number (with respect to the two-norm). The output array *s* returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix *B* with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1. This choice of *s* puts the condition number of *B* within a factor *n* of the smallest possible condition number over all possible diagonal scalings.

See [?laqsb](#) auxiliary function that uses scaling factors computed by [?pbequ](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is packed in the array <i>ab</i> : If <i>uplo</i> = 'U', the array <i>ab</i> stores the upper triangular part of the matrix <i>A</i> . If <i>uplo</i> = 'L', the array <i>ab</i> stores the lower triangular part of the matrix <i>A</i> .
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>ab</i>	REAL for spbequ DOUBLE PRECISION for dpbequ COMPLEX for cpbequ DOUBLE COMPLEX for zpbequ .

Array, DIMENSION (*ldab*, *).

The array *ap* contains either the upper or the lower triangular part of the matrix *A* (as specified by *uplo*) in *band storage* (see [Matrix Storage Schemes](#)).

The second dimension of *ab* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of the array *ab*; $ldab \geq kd + 1$.

Output Parameters

s REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION (*n*).
If *info* = 0, the array *s* contains the scale factors for *A*.

scond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
If *info* = 0, *scond* contains the ratio of the smallest *s*(*i*) to the largest *s*(*i*).

amax REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Absolute value of the largest element of the matrix *A*.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, the *i*-th diagonal element of *A* is nonpositive.

Fortran 95 Interface Notes

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If $scond \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by s .

If $amax$ is very close to overflow or very close to underflow, the matrix A should be scaled.

Driver Routines

Table 3-3 lists the LAPACK driver routines for solving systems of linear equations with real or complex matrices.

Table 3-3 Driver Routines for Solving Systems of Linear Equations

Matrix type, storage scheme	Simple Driver	Expert Driver
general	?gesv	?gesvx
general band	?gbsv	?gbsvx
general tridiagonal	?gtsv	?gtsvx
symmetric/Hermitian positive-definite	?posv	?posvx
symmetric/Hermitian positive-definite, storage	?ppsv	?ppsvx
symmetric/Hermitian positive-definite, band	?pbsv	?pbsvx
symmetric/Hermitian positive-definite, tridiagonal	?ptsv	?ptsvx
symmetric/Hermitian indefinite	?sysv/?hesv	?sysvx/?hesvx
symmetric/Hermitian indefinite, packed storage	?spsv/?hpsv	?spsvx/?hpsvx
complex symmetric	?sysv	?sysvx
complex symmetric, packed storage	?spsv	?spsvx

In this table α stands for s (single precision real), d (double precision real), c (single precision complex), or z (double precision complex). In the description of `?gesv` routine α stands for combined character codes ds and zc for the mixed precision subroutines.

?gesv

Computes the solution to the system of linear equations with a square matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call dgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call cgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call zgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call dsgesv( n, nrhs, a, lda, ipiv, b, ldb, x, ldx, work, swork, iter, info )
call zcgesv( n, nrhs, a, lda, ipiv, b, ldb, x, ldx, work, swork, iter, info )
```

Fortran 95:

```
call gesv( a, b [,ipiv] [,info] )
```

Description

This routine solves for X the system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = P \cdot L \cdot U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A \cdot X = B$.

The `dsgesv` and `zcgesv` are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (`dsgesv`) or single complex precision (`zcgesv`) and use this factorization within an iterative refinement procedure to produce a solution with double precision (`dsgesv`) / double complex

precision (`zcgesv`) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision performance over double precision performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to `ilaenv` in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

```
iter > itermax
```

or for all the right-hand sides:

```
rnrm < sqrt(n)*xnrm*anrm*eps*bwdmax,
```

where

- `iter` is the number of the current iteration in the iterative refinement process
- `rnrm` is the infinity-norm of the residual
- `xnrm` is the infinity-norm of the solution
- `anrm` is the infinity-operator-norm of the matrix A
- `eps` is the machine epsilon returned by `dlamch` ('Epsilon').

The values `itermax` and `bwdmax` are fixed to 30 and 1.0d+00 respectively.

Input Parameters

<code>n</code>	INTEGER. The number of linear equations, that is, the order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<code>a, b</code>	REAL for <code>sgesv</code> DOUBLE PRECISION for <code>dgesv</code> and <code>dsgesv</code> COMPLEX for <code>cgesv</code> DOUBLE COMPLEX for <code>zgesv</code> and <code>zcgesv</code> . Arrays: <code>a(lda,*)</code> , <code>b(ldb,*)</code> . The array <code>a</code> contains the n -by- n coefficient matrix A .

The array b contains the n -by- $nrhs$ matrix of right hand side matrix B . The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.

lda INTEGER. The leading dimension of the array a ; $lda \geq \max(1, n)$.

ldb INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, nrhs)$.

ldx INTEGER. The leading dimension of the array x ; $ldx \geq \max(1, n)$.

$work$ DOUBLE PRECISION for `dsgesv`
DOUBLE COMPLEX for `zcgesv`.
Workspace array, DIMENSION at least $\max(1, n*nrhs)$. This array is used to hold the residual vectors.

$swork$ REAL for `dsgesv`
COMPLEX for `zcgesv`.
Workspace array, DIMENSION at least $\max(1, n*nrhs)$. This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.

Output Parameters

a Overwritten by the factors L and U from the factorization of $A = P*L*U$; the unit diagonal elements of L are not stored.
If iterative refinement has been successfully used ($info=0$ and $iter \geq 0$, see description below), then A is unchanged.
If double precision factorization has been used ($info=0$ and $iter < 0$, see description below), then the array A contains the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

b Overwritten by the solution matrix X for `dgesv`, `sgesv`, `zgesv`, `zgesv`.
Unchanged for `dsgesv` and `zcgesv`.

$ipiv$ INTEGER.
Array, DIMENSION at least $\max(1, n)$. The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $ipiv(i)$. Corresponds to the single precision factorization (if $info=0$ and $iter \geq 0$) or the double precision factorization (if $info=0$ and $iter < 0$).

x DOUBLE PRECISION for `dsgesv`

iter DOUBLE COMPLEX for *zcgsv*.
 Array, DIMENSION (*ldx*, *nrhs*). If *info* = 0, contains the *n*-by-*nrhs* solution matrix *X*.

iter INTEGER.
 If *iter* < 0: iterative refinement has failed, double precision factorization has been performed

- If *iter* = -1: taking into account machine parameters, *n*, *nrhs*, it is a priori not worth working in single precision
- If *iter* = -2: overflow of an entry when moving from double to single precision
- If *iter* = -3: failure of *sgetrf*
- If *iter* = -31: stop the iterative refinement after the 30th iteration.

If *iter* > 0: iterative refinement has been successfully used. Returns the number of iterations.

info INTEGER. If *info*=0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, *U*(*i*, *i*) (computed in double precision for mixed precision subroutines) is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gesv* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ipiv</i>	Holds the vector of length (<i>n</i>).

NOTE. Fortran 95 Interface is so far not available for the mixed precision subroutines *dsgsv*/*zcgsv*.

?gesvx

Computes the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
ldb, x, ldx, rcond, ferr, berr, work, iwork, info )

call dgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
ldb, x, ldx, rcond, ferr, berr, work, iwork, info )

call cgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
ldb, x, ldx, rcond, ferr, berr, work, rwork, info )

call zgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
ldb, x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gesvx( a, b, x [,af] [,ipiv] [,fact] [,trans] [,equed] [,r] [,c] [,ferr]
[,berr] [,rcond] [,rpvgrw] [,info] )
```

Description

This routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gesvx performs the following steps:

1. If $fact = 'E'$, real scaling factors r and c are computed to equilibrate the system:

$$trans = 'N': diag(r) \cdot A \cdot diag(c) \cdot inv(diag(c)) \cdot X = diag(r) \cdot B$$

$$trans = 'T': (diag(r) \cdot A \cdot diag(c))^T \cdot inv(diag(r)) \cdot X = diag(c) \cdot B$$

$$trans = 'C': (diag(r) \cdot A \cdot diag(c))^H \cdot inv(diag(r)) \cdot X = diag(c) \cdot B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and B by $\text{diag}(r) * B$ (if $\text{trans} = 'N'$) or $\text{diag}(c) * B$ (if $\text{trans} = 'T'$ or $'C'$).

2. If $\text{fact} = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $\text{fact} = 'E'$) as $A = P * L * U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $\text{info} = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $\text{info} = n + 1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
4. The system of equations is solved for x using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix x is premultiplied by $\text{diag}(c)$ (if $\text{trans} = 'N'$) or $\text{diag}(r)$ (if $\text{trans} = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

fact

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $\text{fact} = 'F'$: on entry, af and $ipiv$ contain the factored form of A .

If equed is not 'N', the matrix A has been equilibrated with scaling factors given by r and c .

a , af , and $ipiv$ are not modified.

If $\text{fact} = 'N'$, the matrix A will be copied to af and factored.

If $\text{fact} = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.

trans

CHARACTER*1. Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

If $\text{trans} = 'N'$, the system has the form $A * X = B$ (No transpose).

If $\text{trans} = 'T'$, the system has the form $A^T * X = B$ (Transpose).

If $\text{trans} = 'C'$, the system has the form $A^H * X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).

<i>n</i>	INTEGER. The number of linear equations; the order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides; the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$.
<i>a,af,b,work</i>	REAL for sgesvx DOUBLE PRECISION for dgesvx COMPLEX for cgesvx DOUBLE COMPLEX for zgesvx. Arrays: <i>a</i>(<i>lda</i>,*), <i>af</i>(<i>ldaf</i>,*), <i>b</i>(<i>ldb</i>,*), <i>work</i>(*). The array <i>a</i> contains the matrix <i>A</i>. If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then <i>A</i> must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the factored form of the matrix <i>A</i>, that is, the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$ as computed by ?getrf. If <i>equed</i> is not 'N', then <i>af</i> is the factored form of the equilibrated matrix <i>A</i>. The second dimension of <i>af</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 4 * n)$ for real flavors, and at least $\max(1, 2 * n)$ for complex flavors.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains the pivot indices from the factorization $A = P * L * U$ as computed by ?getrf; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i>(<i>i</i>).
<i>equed</i>	CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:

If `equed = 'N'`, no equilibration was done (always true if `fact = 'N'`).

If `equed = 'R'`, row equilibration was done, that is, *A* has been premultiplied by `diag(r)`.

If `equed = 'C'`, column equilibration was done, that is, *A* has been postmultiplied by `diag(c)`.

If `equed = 'B'`, both row and column equilibration was done, that is, *A* has been replaced by `diag(r)*A*diag(c)`.

r, c
REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Arrays: `r(n)`, `c(n)`. The array *r* contains the row scale factors for *A*, and the array *c* contains the column scale factors for *A*. These arrays are input arguments if `fact = 'F'` only; otherwise they are output arguments.

If `equed = 'R'` or `'B'`, *A* is multiplied on the left by `diag(r)`; if `equed = 'N'` or `'C'`, *r* is not accessed.

If `fact = 'F'` and `equed = 'R'` or `'B'`, each element of *r* must be positive.

If `equed = 'C'` or `'B'`, *A* is multiplied on the right by `diag(c)`; if `equed = 'N'` or `'R'`, *c* is not accessed.

If `fact = 'F'` and `equed = 'C'` or `'B'`, each element of *c* must be positive.

ldx
INTEGER. The first dimension of the output array *x*; `ldx ≥ max(1, n)`.

iwork
INTEGER. Workspace array, **DIMENSION** at least `max(1, n)`; used in real flavors only.

rwork
REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, **DIMENSION** at least `max(1, 2*n)`; used in complex flavors only.

Output Parameters

x
REAL for sgesvx
DOUBLE PRECISION for dgesvx
COMPLEX for cgesvx
DOUBLE COMPLEX for zgesvx.

	Array, DIMENSION ($ldx, *$). If $info = 0$ or $info = n+1$, the array x contains the solution matrix x to the <i>original</i> system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the <i>equilibrated</i> system is: $diag(C)^{-1} * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; $diag(R)^{-1} * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$. The second dimension of x must be at least $\max(1, nrhs)$.
<i>a</i>	Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$. If $equed \neq 'N'$, A is scaled on exit as follows: $equed = 'R'$: $A = diag(R) * A$ $equed = 'C'$: $A = A * diag(c)$ $equed = 'B'$: $A = diag(R) * A * diag(c)$.
<i>af</i>	If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = PLU$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $diag(r) * B$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$; overwritten by $diag(c) * B$ if $trans = 'T'$ or $'C'$ and $equed = 'C'$ or $'B'$; not changed if $equed = 'N'$.
<i>r, c</i>	These arrays are output arguments if $fact \neq 'F'$. See the description of r, c in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j-th column of the solution matrix X). If $xtrue$ is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the

	largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix A (if <i>fact</i> = 'N') or of the equilibrated matrix A (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work, rwork</i>	On exit, <i>work</i> (1) for real flavors, or <i>rwork</i> (1) for complex flavors, contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If <i>work</i> (1) for real flavors, or <i>rwork</i> (1) for complex flavors is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution x , condition estimator <i>rcond</i> , and forward error bound <i>ferr</i> could be unreliable. If factorization fails with $0 < info \leq n$, then <i>work</i> (1) for real flavors, or <i>rwork</i> (1) for complex flavors contains the reciprocal pivot growth factor for the leading <i>info</i> columns of A .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n+1$, then U is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesvx` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Holds the matrix <i>AF</i> of size (n, n) .
<i>ipiv</i>	Holds the vector of length (n) .
<i>r</i>	Holds the vector of length (n) . Default value for each element is $r(i) = 1.0\_WP$.
<i>c</i>	Holds the vector of length (n) . Default value for each element is $c(i) = 1.0\_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>equed</i>	Must be 'N', 'B', 'C', or 'R'. The default value is 'N'.
<i>rpvgrw</i>	Real value that contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$.

?gbsv

Computes the solution to the system of linear equations with a band matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call dgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call cgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call zgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
```

Fortran 95:

```
call gbsv( a, b [,kl] [,ipiv] [,info] )
```

Description

This routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n band matrix with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L^*U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl+ku$ superdiagonals. The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

n	INTEGER. The order of A . The number of rows in B ; $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides. The number of columns in B ; $nrhs \geq 0$.
ab, b	REAL for sgbsv DOUBLE PRECISION for dgbsv COMPLEX for cgbsv

DOUBLE COMPLEX for zgbsv.

Arrays: $ab(ldab, *)$, $b ldb, *)$.

The array ab contains the matrix A in band storage (see [Matrix Storage Schemes](#)). The second dimension of ab must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$ldab$ INTEGER. The first dimension of the array ab . ($ldab \geq 2kl + ku + 1$)

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ab Overwritten by L and U . The diagonal and $kl + ku$ superdiagonals of U are stored in the first $1 + kl + ku$ rows of ab . The multipliers used to form L are stored in the next kl rows.

b Overwritten by the solution matrix X .

$ipiv$ INTEGER.
Array, DIMENSION at least $\max(1, n)$. The pivot indices: row i was interchanged with row $ipiv(i)$.

$info$ INTEGER. If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbsv` interface are as follows:

a Stands for argument ab in Fortran 77 interface. Holds the array A of size $(2*kl+ku+1, n)$.

b Holds the matrix B of size $(n, nrhs)$.

$ipiv$ Holds the vector of length (n) .

kl If omitted, assumed $kl = ku$.

ku

Restored as $ku = lda - 2 * kl - 1$.

?gbsvx

Computes the solution to the real or complex system of linear equations with a band matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, iwork, info )

call dgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, iwork, info )

call cgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, rwork, info )

call zgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gbsvx( a, b, x [,kl] [,af] [,ipiv] [,fact] [,trans] [,equed] [,r] [,c]
[,ferr] [,berr] [,rcond] [,rpvgrw] [,info] )
```

Description

This routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A * X = B$, $A^T * X = B$, or $A^H * X = B$, where A is a band matrix of order n with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gbsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors r and c are computed to equilibrate the system:

$$trans = 'N': diag(r) * A * diag(c) * inv(diag(c)) * X = diag(r) * B$$

$$trans = 'T': (diag(r) * A * diag(c))^T * inv(diag(r)) * X = diag(c) * B$$

$trans = 'C': (diag(r)*A*diag(c))^H * inv(diag(r)) * X = diag(c) * B$

Whether the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(r)*A*diag(c)$ and B by $diag(r)*B$ (if $trans='N'$) or $diag(c)*B$ (if $trans = 'T'$ or $'C'$).

2. If $fact = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as $A = L*U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl+ku$ superdiagonals.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(c)$ (if $trans = 'N'$) or $diag(r)$ (if $trans = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

fact

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, *afb* and *ipiv* contain the factored form of A . If *equed* is not 'N', the matrix A is equilibrated with scaling factors given by *r* and *c*.

ab, *afb*, and *ipiv* are not modified.

If $fact = 'N'$, the matrix A will be copied to *afb* and factored.

If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to *afb* and factored.

trans

CHARACTER*1. Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:

If $trans = 'N'$, the system has the form $A*X = B$ (No transpose).

If $trans = 'T'$, the system has the form $A^T*X = B$ (Transpose).

	If <i>trans</i> = 'C', the system has the form $A^H * X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).
<i>n</i>	INTEGER. The number of linear equations, the order of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides, the number of columns of the matrices <i>B</i> and <i>X</i> ; $nrhs \geq 0$.
<i>ab,afb,b,work</i>	REAL for sgesvx DOUBLE PRECISION for dgesvx COMPLEX for cgesvx DOUBLE COMPLEX for zgesvx. Arrays: <i>a(lda,*)</i> , <i>af(ldaf,*)</i> , <i>b(ldb,*)</i> , <i>work(*)</i> . The array <i>ab</i> contains the matrix <i>A</i> in band storage (see Matrix Storage Schemes). The second dimension of <i>ab</i> must be at least $\max(1, n)$. If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then <i>A</i> must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i> . The array <i>afb</i> is an input argument if <i>fact</i> = 'F'. The second dimension of <i>afb</i> must be at least $\max(1, n)$. It contains the factored form of the matrix <i>A</i> , that is, the factors <i>L</i> and <i>U</i> from the factorization $A = L * U$ as computed by ?gbtrf. <i>U</i> is stored as an upper triangular band matrix with $kl + ku$ superdiagonals in the first $1 + kl + ku$ rows of <i>afb</i> . The multipliers used during the factorization are stored in the next <i>kl</i> rows. If <i>equed</i> is not 'N', then <i>afb</i> is the factored form of the equilibrated matrix <i>A</i> . The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> ; $ldab \geq kl + ku + 1$.
<i>ldaafb</i>	INTEGER. The first dimension of <i>afb</i> ; $ldaafb \geq 2*kl + ku + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, nrhs)$.

<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains the pivot indices from the factorization $A = L*U$ as computed by ?gbtrf; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i>(<i>i</i>).
<i>equed</i>	CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'). If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag</i>(<i>r</i>). If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag</i>(<i>c</i>). if <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by <i>diag</i>(<i>r</i>)*<i>A</i>*<i>diag</i>(<i>c</i>).
<i>r, c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>r</i>(<i>n</i>), <i>c</i>(<i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>. These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i>(<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i>(<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i>; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Workspace array, `DIMENSION` at least `max(1, n)`; used in complex flavors only.

Output Parameters

<code>x</code>	REAL for <code>sghbsvx</code> DOUBLE PRECISION for <code>dghbsvx</code> COMPLEX for <code>cghbsvx</code> DOUBLE COMPLEX for <code>zghbsvx</code>. Array, <code>DIMENSION (ldx,*)</code>. If <code>info = 0</code> or <code>info = n+1</code>, the array <code>x</code> contains the solution matrix <code>x</code> to the <i>original</i> system of equations. Note that <code>A</code> and <code>B</code> are modified on exit if <code>equed</code> $\neq$ 'N', and the solution to the <i>equilibrated</i> system is: <code>inv(diag(c))*X</code>, if <code>trans = 'N'</code> and <code>equed = 'C'</code> or 'B'; <code>inv(diag(r))*X</code>, if <code>trans = 'T'</code> or 'C' and <code>equed = 'R'</code> or 'B'. The second dimension of <code>x</code> must be at least <code>max(1, nrhs)</code>.
<code>ab</code>	Array <code>ab</code> is not modified on exit if <code>fact = 'F'</code> or 'N', or if <code>fact = 'E'</code> and <code>equed = 'N'</code>. If <code>equed</code> $\neq$ 'N', <code>A</code> is scaled on exit as follows: <code>equed = 'R': A = diag(r)*A</code> <code>equed = 'C': A = A*diag(c)</code> <code>equed = 'B': A = diag(r)*A*diag(c)</code>.
<code>afb</code>	If <code>fact = 'N'</code> or 'E', then <code>afb</code> is an output argument and on exit returns details of the <i>LU</i> factorization of the original matrix <code>A</code> (if <code>fact = 'N'</code>) or of the equilibrated matrix <code>A</code> (if <code>fact = 'E'</code>). See the description of <code>ab</code> for the form of the equilibrated matrix.
<code>b</code>	Overwritten by <code>diag(r)*b</code> if <code>trans = 'N'</code> and <code>equed = 'R'</code> or 'B'; overwritten by <code>diag(c)*b</code> if <code>trans = 'T'</code> or 'C' and <code>equed = 'C'</code> or 'B'; not changed if <code>equed = 'N'</code>.
<code>r, c</code>	These arrays are output arguments if <code>fact</code> $\neq$ 'F'. See the description of <code>r, c</code> in <i>Input Arguments</i> section.
<code>rcond</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <code>A</code> after equilibration (if done).

	If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j-th column of the solution matrix X). If <i>xtrue</i> is the true solution corresponding to $x(j)$, <i>ferr</i>(j) is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work, rwork</i>	On exit, <i>work</i>(1) for real flavors, or <i>rwork</i>(1) for complex flavors, contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If <i>work</i>(1) for real flavors, or <i>rwork</i>(1) for complex flavors is much less than 1, then the stability of the <i>LU</i> factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>x</i>, condition estimator <i>rcond</i>, and forward error bound <i>ferr</i> could be unreliable. If factorization fails with $0 < info \leq n$, then <i>work</i>(1) for real flavors, or <i>rwork</i>(1) for complex flavors contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i>.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned. If $info = i$, and $i = n+1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbsvx` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kl+ku+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(2*kl+ku+1, n)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>r</i>	Holds the vector of length (n) . Default value for each element is $r(i) = 1.0\_WP$.
<i>c</i>	Holds the vector of length (n) . Default value for each element is $c(i) = 1.0\_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>equed</i>	Must be 'N', 'B', 'C', or 'R'. The default value is 'N'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

<i>rpvgrw</i>	Real value that contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda - kl - 1$.

?gtsv

Computes the solution to the system of linear equations with a tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgtsv( n, nrhs, dl, d, du, b, ldb, info )
call dgtsv( n, nrhs, dl, d, du, b, ldb, info )
call cgtsv( n, nrhs, dl, d, du, b, ldb, info )
call zgtsv( n, nrhs, dl, d, du, b, ldb, info )
```

Fortran 95:

```
call gtsv( dl, d, du, b [,info] )
```

Description

This routine solves for X the system of linear equations $A * X = B$, where A is an n -by- n tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. The routine uses Gaussian elimination with partial pivoting.

Note that the equation $A^T * X = B$ may be solved by interchanging the order of the arguments du and dl .

Input Parameters

<i>n</i>	INTEGER. The order of A , the number of rows in B ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>dl, d, du, b</i>	REAL for sgtsv DOUBLE PRECISION for dgtsv

COMPLEX for `cgtsv`

DOUBLE COMPLEX for `zgtsv`.

Arrays: `dl(n - 1)`, `d(n)`, `du(n - 1)`, `b(ldb,*)`.

The array `dl` contains the $(n - 1)$ subdiagonal elements of A .

The array `d` contains the diagonal elements of A .

The array `du` contains the $(n - 1)$ superdiagonal elements of A .

The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of `b` must be at least $\max(1, nrhs)$.

`ldb`

INTEGER. The first dimension of `b`; $ldb \geq \max(1, n)$.

Output Parameters

`dl`

Overwritten by the $(n-2)$ elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A . These elements are stored in `dl(1)`, $\dots$, `dl(n-2)`.

`d`

Overwritten by the n diagonal elements of U .

`du`

Overwritten by the $(n-1)$ elements of the first superdiagonal of U .

`b`

Overwritten by the solution matrix X .

`info`

INTEGER. If `info` = 0, the execution is successful.

If `info` = $-i$, the i -th parameter had an illegal value.

If `info` = i , $U(i, i)$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtsv` interface are as follows:

`dl`

Holds the vector of length $(n-1)$.

`d`

Holds the vector of length (n) .

`du`

Holds the vector of length $(n-1)$.

`b`

Holds the matrix B of size $(n, nrhs)$.

?gtsvx

Computes the solution to the real or complex system of linear equations with a tridiagonal matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call dgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call cgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, rwork, info )

call zgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gtsvx( dl, d, du, b, x [,dlf] [,df] [,duf] [,du2] [,ipiv] [,fact] [,trans]
[,ferr] [,berr] [,rcond] [,info] )
```

Description

This routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, $A^T X = B$, or $A^H X = B$, where A is a tridiagonal matrix of order n , the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gtsvx performs the following steps:

1. If $fact = 'N'$, the LU decomposition is used to factor the matrix A as $A = L^*U$, where L is a product of permutation and unit lower bidiagonal matrices and U is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals.

2. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If <i>fact</i> = 'F': on entry, <i>dlf</i>, <i>df</i>, <i>duf</i>, <i>du2</i>, and <i>ipiv</i> contain the factored form of A; arrays <i>dl</i>, <i>d</i>, <i>du</i>, <i>dlf</i>, <i>df</i>, <i>duf</i>, <i>du2</i>, and <i>ipiv</i> will not be modified. If <i>fact</i> = 'N', the matrix A will be copied to <i>dlf</i>, <i>df</i>, and <i>duf</i> and factored.
<i>trans</i>	CHARACTER*1. Must be 'N', 'T', or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$ (No transpose). If <i>trans</i> = 'T', the system has the form $A^T * X = B$ (Transpose). If <i>trans</i> = 'C', the system has the form $A^H * X = B$ (Conjugate transpose).
<i>n</i>	INTEGER. The number of linear equations, the order of the matrix A; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides, the number of columns of the matrices B and X; $nrhs \geq 0$.
<i>dl,d,du,dlf,df,duf,du2,b,</i>	REAL for sgtsvx DOUBLE PRECISION for dgtsvx COMPLEX for cgtsvx
<i>x,work</i>	DOUBLE COMPLEX for zgtsvx. Arrays: <i>dl</i>, dimension $(n - 1)$, contains the subdiagonal elements of A. <i>d</i>, dimension (n), contains the diagonal elements of A. <i>du</i>, dimension $(n - 1)$, contains the superdiagonal elements of A.

d1f, dimension $(n-1)$. If *fact* = 'F' , then *d1f* is an input argument and on entry contains the $(n-1)$ multipliers that define the matrix *L* from the *LU* factorization of *A* as computed by [?gttrf](#).

df, dimension (n) . If *fact* = 'F' , then *df* is an input argument and on entry contains the n diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.

duf, dimension $(n-1)$. If *fact* = 'F' , then *duf* is an input argument and on entry contains the $(n-1)$ elements of the first superdiagonal of *U*.

du2, dimension $(n-2)$. If *fact* = 'F' , then *du2* is an input argument and on entry contains the $(n-2)$ elements of the second superdiagonal of *U*.

b(*ldb**) contains the right-hand side matrix *B*. The second dimension of *b* must be at least $\max(1, nrhs)$.

x(*ldx**) contains the solution matrix *X*. The second dimension of *x* must be at least $\max(1, nrhs)$.

work(*) is a workspace array;

the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ldx INTEGER. The first dimension of *x*; $ldx \geq \max(1, n)$.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. If *fact* = 'F' , then *ipiv* is an input argument and on entry contains the pivot indices, as returned by [?gttrf](#).

iwork INTEGER. Workspace array, DIMENSION (n) . Used for real flavors only.

rwork REAL for *cgtsvx*

DOUBLE PRECISION for *zgtsvx*.

Workspace array, DIMENSION (n) . Used for complex flavors only.

Output Parameters

x REAL for *sgtsvx*
 DOUBLE PRECISION for *dgtsvx*
 COMPLEX for *cgtsvx*
 DOUBLE COMPLEX for *zgtsvx*.
 Array, DIMENSION $(ldx, *)$.

	If $info = 0$ or $info = n+1$, the array x contains the solution matrix X . The second dimension of x must be at least $\max(1, nrhs)$.
<i>d1f</i>	If $fact = 'N'$, then <i>d1f</i> is an output argument and on exit contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
<i>df</i>	If $fact = 'N'$, then <i>df</i> is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A .
<i>d1f</i>	If $fact = 'N'$, then <i>d1f</i> is an output argument and on exit contains the $(n-1)$ elements of the first superdiagonal of U .
<i>du2</i>	If $fact = 'N'$, then <i>du2</i> is an output argument and on exit contains the $(n-2)$ elements of the second superdiagonal of U .
<i>ipiv</i>	The array <i>ipiv</i> is an output argument if $fact = 'N'$ and, on exit, contains the pivot indices from the factorization $A = L*U$; row i of the matrix was interchanged with row <i>ipiv</i> (i). The value of <i>ipiv</i> (i) will always be i or $i+1$; <i>ipiv</i> (i)= i indicates a row interchange was not required.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A . If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> =0), the matrix is singular to working precision. This condition is indicated by a return code of $info>0$.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If x_{true} is the true solution corresponding to $x(j)$, <i>ferr</i> (j) is an estimated upper bound for the magnitude of the largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

info

INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has not been completed unless $i = n$, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned. If *info* = *i*, and $i = n + 1$, then U is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtsvx` interface are as follows:

<i>dl</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length (n) .
<i>du</i>	Holds the vector of length $(n-1)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>dlf</i>	Holds the vector of length $(n-1)$.
<i>df</i>	Holds the vector of length (n) .
<i>duf</i>	Holds the vector of length $(n-1)$.
<i>du2</i>	Holds the vector of length $(n-2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.

<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then the arguments <i>dlf</i> , <i>df</i> , <i>duf</i> , <i>du2</i> , and <i>ipiv</i> must be present; otherwise, an error is returned.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

?posv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sposv( uplo, n, nrhs, a, lda, b, ldb, info )
call dposv( uplo, n, nrhs, a, lda, b, ldb, info )
call cposv( uplo, n, nrhs, a, lda, b, ldb, info )
call zposv( uplo, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call posv( a, b [,uplo] [,info] )
```

Description

This routine solves for X the real or complex system of linear equations $A * X = B$, where A is an n -by- n symmetric/Hermitian positive-definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if *uplo* = 'U'

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if *uplo* = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.

	Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
a, b	REAL for <code>sposv</code> DOUBLE PRECISION for <code>dposv</code> COMPLEX for <code>cposv</code> DOUBLE COMPLEX for <code>zposv</code> . Arrays: $a(lda, *)$, $b(l db, *)$. The array a contains the upper or the lower triangular part of the matrix A (see $uplo$). The second dimension of a must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

a	If $info = 0$, the upper or lower triangular part of a is overwritten by the Cholesky factor U or L , as specified by $uplo$.
b	Overwritten by the solution matrix X .
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `posv` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?posvx

*Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric or Hermitian positive definite matrix *A*, and provides error bounds on the solution.*

Syntax

FORTRAN 77:

```
call sposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
rcond, ferr, berr, work, iwork, info )

call dposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
rcond, ferr, berr, work, iwork, info )

call cposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
rcond, ferr, berr, work, rwork, info )

call zposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call posvx( a, b, x [,uplo] [,af] [,fact] [,equed] [,s] [,ferr] [,berr] [,rcond]
[,info] )
```

Description

This routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where *A* is a *n*-by-*n* real symmetric/Hermitian positive definite matrix, the columns of matrix *B* are individual right-hand sides, and the columns of *x* are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?posvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$diag(s) * A * diag(s) * inv(diag(s)) * X = diag(s) * B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s) * A * diag(s)$ and B by $diag(s) * B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$$A = U^T * U \text{ (real)}, A = U^H * U \text{ (complex)}, \text{ if } uplo = 'U',$$

$$\text{or } A = L * L^T \text{ (real)}, A = L * L^H \text{ (complex)}, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

$fact$

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, af contains the factored form of A . If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s .

a and af will not be modified.

If $fact = 'N'$, the matrix A will be copied to af and factored.

If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.

$uplo$

CHARACTER*1. Must be 'U' or 'L'.

	Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
$a, af, b, work$	REAL for <code>sposvx</code> DOUBLE PRECISION for <code>dposvx</code> COMPLEX for <code>cposvx</code> DOUBLE COMPLEX for <code>zposvx</code> . Arrays: $a(lda, *)$, $af(ldaf, *)$, $b(ldb, *)$, $work(*)$. The array a contains the matrix A as specified by $uplo$. If $fact = 'F'$ and $equed = 'Y'$, then A must have been equilibrated by the scaling factors in s , and a must contain the equilibrated matrix $diag(s) * A * diag(s)$. The second dimension of a must be at least $\max(1, n)$. The array af is an input argument if $fact = 'F'$. It contains the triangular factor U or L from the Cholesky factorization of A in the same storage format as A . If $equed$ is not $'N'$, then af is the factored form of the equilibrated matrix $diag(s) * A * diag(s)$. The second dimension of af must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$. $work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.
lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
$ldaf$	INTEGER. The first dimension of af ; $ldaf \geq \max(1, n)$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.
$equed$	CHARACTER*1. Must be $'N'$ or $'Y'$. $equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done: if $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$);

	if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $\text{ldx} \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for cposvx DOUBLE PRECISION for zposvx. Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for sposvx DOUBLE PRECISION for dposvx COMPLEX for cposvx DOUBLE COMPLEX for zposvx. Array, DIMENSION (<i>ldx</i> , *). If <i>info</i> = 0 or <i>info</i> = <i>n</i> +1, the array <i>x</i> contains the solution matrix <i>X</i> to the <i>original</i> system of equations. Note that if <i>equed</i> = 'Y', <i>A</i> and <i>B</i> are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(s)) * X$. The second dimension of <i>x</i> must be at least $\max(1, \text{nrhs})$.
<i>a</i>	Array <i>a</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. If <i>fact</i> = 'E' and <i>equed</i> = 'Y', <i>A</i> is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.
<i>af</i>	If <i>fact</i> = 'N' or 'E', then <i>af</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines)

	of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.
b	Overwritten by $diag(s) * B$, if $equed = 'Y'$; not changed if $equed = 'N'$.
s	This array is an output argument if $fact \neq 'F'$. See the description of s in <i>Input Arguments</i> section.
$rcond$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.
$ferr$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If $xtrue$ is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.
$berr$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
$equed$	If $fact \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in <i>Input Arguments</i> section).
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `posvx` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>s</i>	Holds the vector of length (n) . Default value for each element is $s(i) = 1.0\_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then <i>af</i> must be present; otherwise, an error is returned.
<i>equed</i>	Must be 'N' or 'Y'. The default value is 'N'.

?ppsv

Computes the solution to the system of linear equations with a symmetric (Hermitian) positive definite packed matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sppsv( uplo, n, nrhs, ap, b, ldb, info )
call dppsv( uplo, n, nrhs, ap, b, ldb, info )
call cppsv( uplo, n, nrhs, ap, b, ldb, info )
call zppsv( uplo, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call ppsv( a, b [,uplo] [,info] )
```

Description

This routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n real symmetric/Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.

<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>ap</i> , <i>b</i>	REAL for <i>sppsv</i> DOUBLE PRECISION for <i>dppsv</i> COMPLEX for <i>cppsv</i> DOUBLE COMPLEX for <i>zppsv</i> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*). The array <i>ap</i> contains the upper or the lower triangular part of the matrix <i>A</i> (as specified by <i>uplo</i>) in <i>packed storage</i> (see Matrix Storage Schemes). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>ap</i>	If <i>info</i> = 0, the upper or lower triangular part of <i>A</i> in packed storage is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> .
<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ppsv* interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?ppsvx

Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive definite packed matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, iwork, info )

call dppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, iwork, info )

call cppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, rwork, info )

call zppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, rwork, info )
```

Fortran 95:

```
call ppsvx( a, b, x [,uplo] [,af] [,fact] [,equed] [,s] [,ferr] [,berr] [,rcond]
[,info] )
```

Description

This routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n symmetric or Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ppsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$diag(s)*A*diag(s)*inv(diag(s))*X = diag(s)*B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

- 2.** If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$A = U^T * U$ (real), $A = U^H * U$ (complex), if $uplo = 'U'$,

or $A = L * L^T$ (real), $A = L * L^H$ (complex), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix.

- 3.** If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
- 4.** The system of equations is solved for x using the factored form of A .
- 5.** Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
- 6.** If equilibration was used, the matrix x is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

fact

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, *afp* contains the factored form of A . If *eques* = 'Y', the matrix A has been equilibrated with scaling factors given by s .

ap and *afp* will not be modified.

If $fact = 'N'$, the matrix A will be copied to *afp* and factored.

If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to *afp* and factored.

uplo

CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:

If $uplo = 'U'$, the upper triangle of A is stored.

	If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>ap,afp,b,work</i>	REAL for <i>sppsvx</i> DOUBLE PRECISION for <i>dppsvx</i> COMPLEX for <i>cppsvx</i> DOUBLE COMPLEX for <i>zppsvx</i>. Arrays: <i>ap</i>(*), <i>afp</i>(*), <i>b</i>(<i>ldb</i>,*), <i>work</i>(*). The array <i>ap</i> contains the upper or lower triangle of the original symmetric/Hermitian matrix <i>A</i> in <i>packed storage</i> (see Matrix Storage Schemes). In case when <i>fact</i> = 'F' and <i>equed</i> = 'Y', <i>ap</i> must contain the equilibrated matrix $diag(s) * A * diag(s)$. The array <i>afp</i> is an input argument if <i>fact</i> = 'F' and contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of <i>A</i> in the same storage format as <i>A</i>. If <i>equed</i> is not 'N', then <i>afp</i> is the factored form of the equilibrated matrix <i>A</i>. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. <i>work</i>(*) is a workspace array. The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>equed</i>	CHARACTER*1. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, `DIMENSION (n)`. The array s contains the scale factors for A . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.

If $equed = 'N'$, s is not accessed.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

ldx INTEGER. The first dimension of the output array x ; $ldx \geq \max(1, n)$.

$iwork$ INTEGER. Workspace array, `DIMENSION` at least $\max(1, n)$; used in real flavors only.

$rwork$ REAL for `cppsvx`;
DOUBLE PRECISION for `zppsvx`.
Workspace array, `DIMENSION` at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x REAL for `sppsvx`
DOUBLE PRECISION for `dppsvx`
COMPLEX for `cppsvx`
DOUBLE COMPLEX for `zppsvx`.
Array, `DIMENSION (ldx, *)`.
If $info = 0$ or $info = n+1$, the array x contains the solution matrix X to the *original* system of equations. Note that if $equed = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(s)) * X$. The second dimension of x must be at least $\max(1, nrhs)$.

ap Array ap is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.
If $fact = 'E'$ and $equed = 'Y'$, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

afp If $fact = 'N'$ or $'E'$, then afp is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ (real routines), $A = U^H * U$ or $A = L * L^H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of ap for the form of the equilibrated matrix.

<i>b</i>	Overwritten by $diag(s) * B$, if <i>equed</i> = 'Y'; not changed if <i>equed</i> = 'N'.
<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to $x(j)$, <i>ferr</i> (<i>j</i>) is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned.

If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppsvx` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Stands for argument <i>afp</i> in Fortran 77 interface. Holds the matrix <i>AF</i> of size $(n * (n+1) / 2)$.
<i>s</i>	Holds the vector of length (n) . Default value for each element is $s(i) = 1.0\_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then <i>af</i> must be present; otherwise, an error is returned.
<i>equed</i>	Must be 'N' or 'Y'. The default value is 'N'.

?pbsv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite band matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call spbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call dpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call cpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call zpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call pbsv( a, b [,uplo] [,info] )
```

Description

This routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular band matrix and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.

<i>kd</i>	INTEGER. The number of superdiagonals of the matrix <i>A</i> if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L'; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>ab, b</i>	REAL for spbsv DOUBLE PRECISION for dpbsv COMPLEX for cpbsv DOUBLE COMPLEX for zpbsv. Arrays: <i>ab</i> (<i>ldab</i> , *), <i>b</i> (<i>ldb</i> , *). The array <i>ab</i> contains the upper or the lower triangular part of the matrix <i>A</i> (as specified by <i>uplo</i>) in <i>band storage</i> (see Matrix Storage Schemes). The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>ab</i>	The upper or lower triangular part of <i>A</i> (in band storage) is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> , in the same storage format as <i>A</i> .
<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pbsv* interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?pbsvx

*Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive-definite band matrix *A*, and provides error bounds on the solution.*

Syntax

FORTRAN 77:

```
call spbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call dpbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call cpbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call zpbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )
```

Fortran 95:

```
call pbsvx( a, b, x [,uplo] [,af] [,fact] [,equed] [,s] [,ferr] [,berr] [,rcond]
[,info] )
```

Description

This routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where *A* is a *n*-by-*n* symmetric or Hermitian positive definite band matrix, the columns of matrix *B* are individual right-hand sides, and the columns of *x* are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?pbsvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and B by $\text{diag}(s) * B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T * U \text{ (real)}, A = U^H * U \text{ (complex)}, \text{ if } \text{uplo} = 'U',$$

$$\text{or } A = L * L^T \text{ (real)}, A = L * L^H \text{ (complex)}, \text{ if } \text{uplo} = 'L',$$

where U is an upper triangular band matrix and L is a lower triangular band matrix.

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
4. The system of equations is solved for x using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix x is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

`fact`

CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If `fact = 'E'`: on entry, `afb` contains the factored form of A . If `equed = 'Y'`, the matrix A has been equilibrated with scaling factors given by s .

`ab` and `afb` will not be modified.

If `fact = 'N'`, the matrix A will be copied to `afb` and factored.

	If <i>fact</i> = 'E', the matrix <i>A</i> will be equilibrated if necessary, then copied to <i>afb</i> and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of matrix <i>A</i>; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i>; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in <i>B</i>; $nrhs \geq 0$.
<i>ab,afb,b,work</i>	REAL for spbsvx DOUBLE PRECISION for dpbsvx COMPLEX for cpbsvx DOUBLE COMPLEX for zpbsvx. Arrays: <i>ab</i>(<i>ldab</i>,*), <i>afb</i>(<i>ldab</i>,*), <i>b</i>(<i>ldb</i>,*), <i>work</i>(*). The array <i>ab</i> contains the upper or lower triangle of the matrix <i>A</i> in <i>band storage</i> (see Matrix Storage Schemes). If <i>fact</i> = 'F' and <i>equed</i> = 'Y', then <i>ab</i> must contain the equilibrated matrix <i>diag</i>(<i>s</i>)*<i>A</i>*<i>diag</i>(<i>s</i>). The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>afb</i> is an input argument if <i>fact</i> = 'F'. It contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of the band matrix <i>A</i> in the same storage format as <i>A</i>. If <i>equed</i> = 'Y', then <i>afb</i> is the factored form of the equilibrated matrix <i>A</i>. The second dimension of <i>afb</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of <i>ab</i>; $ldab \geq kd+1$.
<i>ldafb</i>	INTEGER. The first dimension of <i>afb</i>; $ldafb \geq kd+1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.

<i>equed</i>	CHARACTER*1. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N') if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $diag(s) * A * diag(s)$.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i>. This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i>; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for cpbsvx DOUBLE PRECISION for zpbsvx. Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for spbsvx DOUBLE PRECISION for dpbsvx COMPLEX for cpbsvx DOUBLE COMPLEX for zpbsvx. Array, DIMENSION (<i>ldx</i>, *). If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>X</i> to the <i>original</i> system of equations. Note that if <i>equed</i> = 'Y', <i>A</i> and <i>B</i> are modified on exit, and the solution to the equilibrated system is $inv(diag(s)) * X$. The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.
<i>ab</i>	On exit, if <i>fact</i> = 'E' and <i>equed</i> = 'Y', <i>A</i> is overwritten by $diag(s) * A * diag(s)$.

<i>afb</i>	If <i>fact</i> = 'N' or 'E', then <i>afb</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ (real routines), $A=U^H*U$ or $A=L*L^H$ (complex routines) of the original matrix <i>A</i> (if <i>fact</i> = 'N'), or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>ab</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by <i>diag(s)*B</i> , if <i>equed</i> = 'Y'; not changed if <i>equed</i> = 'N'.
<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector <i>x(j)</i> (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to <i>x(j)</i> , <i>ferr(j)</i> is an estimated upper bound for the magnitude of the largest element in (<i>x(j)</i> - <i>xtrue</i>) divided by the magnitude of the largest element in <i>x(j)</i> . The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector <i>x(j)</i> , that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes <i>x(j)</i> an exact solution.
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned. If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbsvx` interface are as follows:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Stands for argument <i>afb</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(kd+1, n)$.
<i>s</i>	Holds the vector of length (n) . Default value for each element is $s(i) = 1.0\_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then <i>af</i> must be present; otherwise, an error is returned.
<i>equed</i>	Must be 'N' or 'Y'. The default value is 'N'.

?ptsv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive definite tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sptsv( n, nrhs, d, e, b, ldb, info )
call dptsv( n, nrhs, d, e, b, ldb, info )
call cptsv( n, nrhs, d, e, b, ldb, info )
call zptsv( n, nrhs, d, e, b, ldb, info )
```

Fortran 95:

```
call ptsv( d, e, b [,info] )
```

Description

This routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive-definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

A is factored as $A = L^*D^*L^T$ (real flavors) or $A = L^*D^*L^H$ (complex flavors), and the factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
d	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, dimension at least $\max(1, n)$. Contains the diagonal elements of the tridiagonal matrix A .
e, b	REAL for sptsv DOUBLE PRECISION for dptsv

COMPLEX for `cptsv`

DOUBLE COMPLEX for `zptsv`.

Arrays: $e(n - 1)$, $b(l\text{db}, *)$. The array e contains the $(n - 1)$ subdiagonal elements of A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb

INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

d

Overwritten by the n diagonal elements of the diagonal matrix D from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of A .

e

Overwritten by the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor L from the factorization of A .

b

Overwritten by the solution matrix X .

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptsv` interface are as follows:

d

Holds the vector of length (n) .

e

Holds the vector of length $(n-1)$.

b

Holds the matrix B of size $(n, nrhs)$.

?ptsvx

Uses factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive definite tridiagonal matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, info )

call dptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, info )

call cptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, rwork, info )

call zptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, rwork, info )
```

Fortran 95:

```
call ptsvx( d, e, b, x [,df] [,ef] [,fact] [,ferr] [,berr] [,rcond] [,info] )
```

Description

This routine uses the Cholesky factorization $A = L^*D*L^T$ (real)/ $A = L^*D*L^H$ (complex) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n symmetric or Hermitian positive definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ptsvx performs the following steps:

1. If *fact* = 'N', the matrix A is factored as $A = L^*D*L^T$ (real flavors)/ $A = L^*D*L^H$ (complex flavors), where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^T*D*U$ (real flavors)/ $A = U^H*D*U$ (complex flavors).

2. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A is supplied on entry. If <i>fact</i> = 'F': on entry, <i>df</i> and <i>ef</i> contain the factored form of A. Arrays <i>d</i>, <i>e</i>, <i>df</i>, and <i>ef</i> will not be modified. If <i>fact</i> = 'N', the matrix A will be copied to <i>df</i> and <i>ef</i>, and factored.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.
<i>d</i> , <i>df</i> , <i>rwork</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>d</i>(<i>n</i>), <i>df</i>(<i>n</i>), <i>rwork</i>(<i>n</i>). The array <i>d</i> contains the n diagonal elements of the tridiagonal matrix A. The array <i>df</i> is an input argument if <i>fact</i> = 'F' and on entry contains the n diagonal elements of the diagonal matrix D from the $L^*D^*L^T$ (real)/$L^*D^*L^H$ (complex) factorization of A. The array <i>rwork</i> is a workspace array used for complex flavors only.
<i>e</i> , <i>ef</i> , <i>b</i> , <i>work</i>	REAL for sptsvx DOUBLE PRECISION for dptsvx COMPLEX for cptsvx DOUBLE COMPLEX for zptsvx. Arrays: <i>e</i>($n-1$), <i>ef</i>($n-1$), <i>b</i>(<i>ldb</i>*), <i>work</i>(*). The array <i>e</i> contains the $(n-1)$ subdiagonal elements of the tridiagonal matrix A.

The array *ef* is an input argument if *fact* = 'F' and on entry contains the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor *L* from the L^*D*L^T (real)/ L^*D*L^H (complex) factorization of *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

The array *work* is a workspace array. The dimension of *work* must be at least $2*n$ for real flavors, and at least n for complex flavors.

ldb INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

ldx INTEGER. The leading dimension of *x*; $ldx \geq \max(1, n)$.

Output Parameters

x REAL for sptsvx
DOUBLE PRECISION for dptsvx
COMPLEX for cptsvx
DOUBLE COMPLEX for zptsvx.
Array, DIMENSION (*ldx*, *).
If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *x* to the system of equations. The second dimension of *x* must be at least $\max(1, nrhs)$.

df, *ef* These arrays are output arguments if *fact* = 'N'. See the description of *df*, *ef* in *Input Arguments* section.

rcond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
An estimate of the reciprocal condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector *x*(*j*) (the *j*-th column of the solution matrix *X*). If *xtrue* is the true solution corresponding to *x*(*j*), *ferr*(*j*) is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in *x*(*j*). The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value. If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned. If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptsvx` interface are as follows:

<i>d</i>	Holds the vector of length (n) .
<i>e</i>	Holds the vector of length $(n-1)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>df</i>	Holds the vector of length (n) .
<i>ef</i>	Holds the vector of length $(n-1)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If $fact = 'F'$, then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

?sysv

Computes the solution to the system of linear equations with a real or complex symmetric matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call ssysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call dsysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call csysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zsysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call sysv( a, b [,uplo] [,ipiv] [,info] )
```

Description

This routine solves for X the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$.
<i>a, b, work</i>	REAL for ssysv

DOUBLE PRECISION for `dsysv`

COMPLEX for `csysv`

DOUBLE COMPLEX for `zsysv`.

Arrays: `a(lda,*)`, `b(ldb,*)`, `work(*)`.

The array `a` contains the upper or the lower triangular part of the symmetric matrix A (see `uplo`). The second dimension of `a` must be at least $\max(1, n)$.

The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of `b` must be at least $\max(1, nrhs)$.

`work` is a workspace array, dimension at least $\max(1, lwork)$.

`lda` INTEGER. The first dimension of `a`; $lda \geq \max(1, n)$.

`ldb` INTEGER. The first dimension of `b`; $ldb \geq \max(1, n)$.

`lwork` INTEGER. The size of the `work` array; $lwork \geq 1$.

If `lwork` = -1, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`. See *Application Notes* below for details and for the suggested value of `lwork`.

Output Parameters

`a` If `info` = 0, `a` is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by `?sytrf`.

`b` If `info` = 0, `b` is overwritten by the solution matrix X .

`ipiv` INTEGER.
Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by `?sytrf`.
If `ipiv(i)` = $k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.
If `uplo` = 'U' and `ipiv(i)` = `ipiv(i-1)` = $-m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

	If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.
<code>work(1)</code>	If $info = 0$, on exit <code>work(1)</code> contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
<code>info</code>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sysv` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be <code>'U'</code> or <code>'L'</code> . The default value is <code>'U'</code> .

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sysvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a real or complex symmetric matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call ssysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
             rcond, ferr, berr, work, lwork, iwork, info )

call dsysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
             rcond, ferr, berr, work, lwork, iwork, info )

call csysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
             rcond, ferr, berr, work, lwork, rwork, info )

call zsysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
             rcond, ferr, berr, work, lwork, rwork, info )
```

Fortran 95:

```
call sysvx( a, b, x [,uplo] [,af] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]
             [,info] )
```

Description

This routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?sysvx performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U*D*U^T$ or $A = L*D*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If $fact = 'F'$: on entry, af and $ipiv$ contain the factored form of A. Arrays a, af, and $ipiv$ will not be modified. If $fact = 'N'$, the matrix A will be copied to af and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.
<i>a,af,b,work</i>	REAL for <code>ssysvx</code> DOUBLE PRECISION for <code>dsysvx</code> COMPLEX for <code>csysvx</code> DOUBLE COMPLEX for <code>zsysvx</code>. Arrays: $a(lda,*)$, $af(ldaf,*)$, $b(ldb,*)$, $work(*)$. The array a contains the upper or the lower triangular part of the symmetric matrix A (see <i>uplo</i>). The second dimension of a must be at least $\max(1, n)$.

The array *af* is an input argument if *fact* = 'F'. It contains the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U * D * U^T$ or $A = L * D * L^T$ as computed by [?sytrf](#). The second dimension of *af* must be at least $\max(1, n)$. The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.

work(*) is a workspace array, dimension at least $\max(1, lwork)$.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i> , as determined by ?sytrf . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the <i>i</i> -th row and column of <i>A</i> was interchanged with the <i>k</i> -th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i-1</i> , and (<i>i-1</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column. If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i+1</i> , and (<i>i+1</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column.
<i>ldx</i>	INTEGER. The leading dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> below for details and for the suggested value of <i>lwork</i> .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for <i>csysvx</i> ; DOUBLE PRECISION for <i>zsysvx</i> .

Workspace array, `DIMENSION` at least `max(1, n)`; used in complex flavors only.

Output Parameters

<code>x</code>	REAL for <code>ssysvx</code> DOUBLE PRECISION for <code>dsysvx</code> COMPLEX for <code>csysvx</code> DOUBLE COMPLEX for <code>zsysvx</code>. Array, <code>DIMENSION (ldx, *)</code>. If <code>info = 0</code> or <code>info = n+1</code>, the array <code>x</code> contains the solution matrix <code>x</code> to the system of equations. The second dimension of <code>x</code> must be at least <code>max(1, nrhs)</code>.
<code>af, ipiv</code>	These arrays are output arguments if <code>fact = 'N'</code>. See the description of <code>af, ipiv</code> in <i>Input Arguments</i> section.
<code>rcond</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <code>A</code>. If <code>rcond</code> is less than the machine precision (in particular, if <code>rcond = 0</code>), the matrix is singular to working precision. This condition is indicated by a return code of <code>info > 0</code>.
<code>ferr</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, <code>DIMENSION</code> at least <code>max(1, nrhs)</code>. Contains the estimated forward error bound for each solution vector <code>x(j)</code> (the <code>j</code>-th column of the solution matrix <code>X</code>). If <code>xtrue</code> is the true solution corresponding to <code>x(j)</code>, <code>ferr(j)</code> is an estimated upper bound for the magnitude of the largest element in <code>(x(j) - xtrue)</code> divided by the magnitude of the largest element in <code>x(j)</code>. The estimate is as reliable as the estimate for <code>rcond</code>, and is almost always a slight overestimate of the true error.
<code>berr</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, <code>DIMENSION</code> at least <code>max(1, nrhs)</code>. Contains the component-wise relative backward error for each solution vector <code>x(j)</code>, that is, the smallest relative change in any element of <code>A</code> or <code>B</code> that makes <code>x(j)</code> an exact solution.
<code>work(1)</code>	If <code>info=0</code>, on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.
 If *info* = *i*, and $i = n + 1$, then *D* is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sysvx* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Holds the matrix <i>AF</i> of size (n, n) .
<i>ipiv</i>	Holds the vector of length (n) .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

Application Notes

For real flavors, *lwork* must be at least $3*n$, and for complex flavors at least $2*n$. For better performance, try using $lwork = n*blocksize$, where *blocksize* is the optimal block size for ?sytrf.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

zhesv

Computes the solution to the system of linear equations with a Hermitian matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call chesv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zhesv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call hesv( a, b [,uplo] [,ipiv] [,info] )
```

Description

This routine solves for X the complex system of linear equations $A * X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U * D * U^H$ or $A = L * D * L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A * X = B$.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <code>uplo</code> = 'U', the array a stores the upper triangular part of the matrix A, and A is factored as $U^*D^*U^H$. If <code>uplo</code> = 'L', the array a stores the lower triangular part of the matrix A, and A is factored as $L^*D^*L^H$.
<code>n</code>	INTEGER. The order of matrix A; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.
<code>a, b, work</code>	COMPLEX for <code>chesv</code> DOUBLE COMPLEX for <code>zhesv</code>. Arrays: <code>a(lda,*)</code>, <code>b(ldb,*)</code>, <code>work(*)</code>. The array a contains the upper or the lower triangular part of the Hermitian matrix A (see <code>uplo</code>). The second dimension of a must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$. <code>work</code> is a workspace array, dimension at least $\max(1, lwork)$.
<code>lda</code>	INTEGER. The first dimension of a; $lda \geq \max(1, n)$.
<code>ldb</code>	INTEGER. The first dimension of b; $ldb \geq \max(1, n)$.
<code>lwork</code>	INTEGER. The size of the <code>work</code> array ($lwork \geq 1$). If <code>lwork</code> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <code>work</code> array, returns this value as the first entry of the <code>work</code> array, and no error message related to <code>lwork</code> is issued by <code>xerbla</code>. See <i>Application Notes</i> below for details and for the suggested value of <code>lwork</code>.

Output Parameters

<code>a</code>	If <code>info</code> = 0, a is overwritten by the block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by <code>?hetrf</code>.
<code>b</code>	If <code>info</code> = 0, b is overwritten by the solution matrix X.

<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D, as determined by ?hetrf. If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i-th row and column of A was interchanged with the k-th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$-th row and column of A was interchanged with the m-th row and column. If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$-th row and column of A was interchanged with the m-th row and column.
<i>work(1)</i>	If $info = 0$, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value. If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesv` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hesvx

Uses the diagonal pivoting factorization to compute the solution to the complex system of linear equations with a Hermitian matrix A, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call chesvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
             rcond, ferr, berr, work, lwork, rwork, info )

call zhesvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
             rcond, ferr, berr, work, lwork, rwork, info )
```

Fortran 95:

```
call hesvx( a, b, x [,uplo] [,af] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]
             [,info] )
```

Description

This routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A^*X = B$, where A is an n -by- n Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?hesvx performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U*D*U^H$ or $A = L*D*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If $fact = 'F'$: on entry, af and $ipiv$ contain the factored form of A. Arrays a, af, and $ipiv$ are not modified. If $fact = 'N'$, the matrix A is copied to af and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If $uplo = 'U'$, the array a stores the upper triangular part of the Hermitian matrix A, and A is factored as $U*D*U^H$. If $uplo = 'L'$, the array a stores the lower triangular part of the Hermitian matrix A; A is factored as $L*D*L^H$.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.
<i>a,af,b,work</i>	COMPLEX for <code>chesvx</code> DOUBLE COMPLEX for <code>zhesvx</code>. Arrays: $a(lda,*)$, $af(ldaf,*)$, $b(ldb,*)$, $work(*)$.

The array *a* contains the upper or the lower triangular part of the Hermitian matrix *A* (see *uplo*). The second dimension of *a* must be at least $\max(1, n)$.

The array *af* is an input argument if *fact* = 'F'. It contains the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ as computed by [?hetrf](#). The second dimension of *af* must be at least $\max(1, n)$.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.

work(*) is a workspace array of dimension at least $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

ldaf INTEGER. The first dimension of *af*; $ldaf \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ipiv INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array *ipiv* is an input argument if *fact* = 'F'. It contains details of the interchanges and the block structure of *D*, as determined by [?hetrf](#).

If *ipiv*(*i*) = *k* > 0, then *d_{ii}* is a 1-by-1 diagonal block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.

If *uplo* = 'U' and *ipiv*(*i*) = *ipiv*(*i*-1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*-1, and (*i*-1)-th row and column of *A* was interchanged with the *m*-th row and column.

If *uplo* = 'L' and *ipiv*(*i*) = *ipiv*(*i*+1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*+1, and (*i*+1)-th row and column of *A* was interchanged with the *m*-th row and column.

ldx INTEGER. The leading dimension of the output array *x*; $ldx \geq \max(1, n)$.

lwork INTEGER. The size of the *work* array.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*. See *Application Notes* below for details and for the suggested value of *lwork*.

rwork REAL for *chesvx*

DOUBLE PRECISION for zhesvx.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	COMPLEX for chesvx DOUBLE COMPLEX for zhesvx. Array, DIMENSION (<i>ldx</i>, *). If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>x</i> to the system of equations. The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.
<i>af</i> , <i>ipiv</i>	These arrays are output arguments if <i>fact</i> = 'N'. See the description of <i>af</i>, <i>ipiv</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for chesvx DOUBLE PRECISION for zhesvx. An estimate of the reciprocal condition number of the matrix <i>A</i>. If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for chesvx DOUBLE PRECISION for zhesvx. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector <i>x</i>(<i>j</i>) (the <i>j</i>-th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to <i>x</i>(<i>j</i>), <i>ferr</i>(<i>j</i>) is an estimated upper bound for the magnitude of the largest element in (<i>x</i>(<i>j</i>) - <i>xtrue</i>) divided by the magnitude of the largest element in <i>x</i>(<i>j</i>). The estimate is as reliable as the estimate for <i>rcon</i>, and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for chesvx DOUBLE PRECISION for zhesvx. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector <i>x</i>(<i>j</i>), that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes <i>x</i>(<i>j</i>) an exact solution.
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then D is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesvx` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>ipiv</i>	Holds the vector of length (n) .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

Application Notes

The value of *lwork* must be at least $2*n$. For better performance, try using $lwork = n*blocksize$, where *blocksize* is the optimal block size for `?hetrf`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spsv

Computes the solution to the system of linear equations with a real or complex symmetric matrix A stored in packed format, and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call dpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call cspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call spsv( a, b [,uplo] [,ipiv] [,info] )
```

Description

This routine solves for *X* the real or complex system of linear equations $A^*X = B$, where *A* is an *n*-by-*n* symmetric matrix stored in packed format, the columns of matrix *B* are individual right-hand sides, and the columns of *X* are the corresponding solutions.

The diagonal pivoting method is used to factor *A* as $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>ap</i> , <i>b</i>	REAL for <i>sspsv</i> DOUBLE PRECISION for <i>dspsv</i> COMPLEX for <i>cspsv</i> DOUBLE COMPLEX for <i>zspsv</i> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor U or L , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>ap</i>	The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by ?spturf , stored as a packed triangular matrix in the same storage format as A .
<i>b</i>	If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix X .
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by ?spturf . If <i>ipiv</i> (<i>i</i>) = <i>k</i> > 0, then d_{ii} is a 1-by-1 block, and the <i>i</i> -th row and column of A was interchanged with the <i>k</i> -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spsv` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?spsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a real or complex symmetric matrix A stored in packed format, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, iwork, info )

call dspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, iwork, info )

call cspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, rwork, info )

call zspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call spsvx( a, b, x [,uplo] [,af] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]
[,info] )
```

Description

This routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?spsvx performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If <i>fact</i> = 'F': on entry, <i>afp</i> and <i>ipiv</i> contain the factored form of A. Arrays <i>ap</i>, <i>afp</i>, and <i>ipiv</i> are not modified. If <i>fact</i> = 'N', the matrix A is copied to <i>afp</i> and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the symmetric matrix A, and A is factored as $U^*D^*U^T$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the symmetric matrix A; A is factored as $L^*D^*L^T$.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.
<i>ap,afp,b,work</i>	REAL for sspsvx DOUBLE PRECISION for dpsvx COMPLEX for cspsvx DOUBLE COMPLEX for zspsvx. Arrays: <i>ap</i>(*), <i>afp</i>(*), <i>b</i>(ldb,*), <i>work</i>(*). The array <i>ap</i> contains the upper or lower triangle of the symmetric matrix A in <i>packed storage</i> (see Matrix Storage Schemes).

The array *afp* is an input argument if *fact* = 'F'. It contains the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U * D * U^T$ or $A = L * D * L^T$ as computed by [?spturf](#), in the same storage format as *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

work(*) is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n+1)/2)$; the second dimension of *b* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

ldb

INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array *ipiv* is an input argument if *fact* = 'F'. It contains details of the interchanges and the block structure of *D*, as determined by [?spturf](#).

If *ipiv*(*i*) = *k* > 0, then *d_{ii}* is a 1-by-1 diagonal block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column.

If *uplo* = 'U' and *ipiv*(*i*) = *ipiv*(*i*-1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*-1, and (*i*-1)-th row and column of *A* was interchanged with the *m*-th row and column.

If *uplo* = 'L' and *ipiv*(*i*) = *ipiv*(*i*+1) = -*m* < 0, then *D* has a 2-by-2 block in rows/columns *i* and *i*+1, and (*i*+1)-th row and column of *A* was interchanged with the *m*-th row and column.

ldx

INTEGER. The leading dimension of the output array *x*; $ldx \geq \max(1, n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork

REAL for *cspsvx*

DOUBLE PRECISION for *zspsvx*.

Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x

REAL for *sspsvx*

DOUBLE PRECISION for *dspsvx*

	COMPLEX for <code>cspsvx</code> DOUBLE COMPLEX for <code>zspsvx</code> . Array, DIMENSION (<code>ldx</code> , *). If <code>info = 0</code> or <code>info = n+1</code> , the array <code>x</code> contains the solution matrix <code>X</code> to the system of equations. The second dimension of <code>x</code> must be at least <code>max(1, nrhs)</code> .
<code>afp, ipiv</code>	These arrays are output arguments if <code>fact = 'N'</code> . See the description of <code>afp, ipiv</code> in <i>Input Arguments</i> section.
<code>rcond</code>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <code>A</code> . If <code>rcond</code> is less than the machine precision (in particular, if <code>rcond = 0</code>), the matrix is singular to working precision. This condition is indicated by a return code of <code>info > 0</code> .
<code>ferr, berr</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least <code>max(1, nrhs)</code> . Contain the component-wise forward and relative backward errors, respectively, for each solution vector.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the <code>i</code> -th parameter had an illegal value. If <code>info = i</code> , and <code>i ≤ n</code> , then <code>d_{ii}</code> is exactly zero. The factorization has been completed, but the block diagonal matrix <code>D</code> is exactly singular, so the solution and error bounds could not be computed; <code>rcond = 0</code> is returned. If <code>info = i</code> , and <code>i = n + 1</code> , then <code>D</code> is nonsingular, but <code>rcond</code> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <code>rcond</code> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spsvx` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Stands for argument <i>afp</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(n * (n+1) / 2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

?hpsv

Computes the solution to the system of linear equations with a Hermitian matrix A stored in packed format, and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call chpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zhpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call hpsv( a, b [,uplo] [,ipiv] [,info] )
```

Description

This routine solves for *x* the system of linear equations $A * X = B$, where *A* is an *n*-by-*n* Hermitian matrix stored in packed format, the columns of matrix *B* are individual right-hand sides, and the columns of *x* are the corresponding solutions.

The diagonal pivoting method is used to factor *A* as $A = U * D * U^H$ or $A = L * D * L^H$, where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B; $nrhs \geq 0$.
<i>ap, b</i>	COMPLEX for <code>chpsv</code> DOUBLE COMPLEX for <code>zhpsv</code>. Arrays: <i>ap</i>(*), <i>b</i>(<i>ldb</i>,*). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor U or L, as specified by <i>uplo</i>, in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.

Output Parameters

<i>ap</i>	The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by ?hptrf, stored as a packed triangular matrix in the same storage format as A.
<i>b</i>	If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix X.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D, as determined by ?hptrf. If <i>ipiv</i>(<i>i</i>) = <i>k</i> > 0, then d_{ii} is a 1-by-1 block, and the <i>i</i>-th row and column of A was interchanged with the <i>k</i>-th row and column. If <i>uplo</i> = 'U' and <i>ipiv</i>(<i>i</i>) = <i>ipiv</i>(<i>i</i>-1) = -<i>m</i> < 0, then D has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i>-1, and (<i>i</i>-1)-th row and column of A was interchanged with the <i>m</i>-th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpsv` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array A of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?hpsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a Hermitian matrix A stored in packed format, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call chpsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, rwork, info )
```

```
call zhpsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call hpsvx( a, b, x [,uplo] [,af] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]
[,info] )
```

Description

This routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A^*X = B$, where A is a n -by- n Hermitian matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?hpsvx` performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is a Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If <code>fact = 'F'</code> : on entry, <code>afp</code> and <code>ipiv</code> contain the factored form of A . Arrays <code>ap</code> , <code>afp</code> , and <code>ipiv</code> are not modified. If <code>fact = 'N'</code> , the matrix A is copied to <code>afp</code> and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored:

If `uplo = 'U'`, the array `ap` stores the upper triangular part of the Hermitian matrix A , and A is factored as $U^*D^*U^H$.

If `uplo = 'L'`, the array `ap` stores the lower triangular part of the Hermitian matrix A , and A is factored as $L^*D^*L^H$.

`n` INTEGER. The order of matrix A ; $n \geq 0$.

`nrhs` INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

`ap,afp,b,work` COMPLEX for `chpsvx`
DOUBLE COMPLEX for `zhpsvx`.
Arrays: `ap(*)`, `afp(*)`, `b(ldb,*)`, `work(*)`.
The array `ap` contains the upper or lower triangle of the Hermitian matrix A in *packed storage* (see [Matrix Storage Schemes](#)).
The array `afp` is an input argument if `fact = 'F'`. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ as computed by [?hptrf](#), in the same storage format as A .
The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations.
`work(*)` is a workspace array.
The dimension of arrays `ap` and `afp` must be at least $\max(1, n(n+1)/2)$; the second dimension of `b` must be at least $\max(1, nrhs)$; the dimension of `work` must be at least $\max(1, 2*n)$.

`ldb` INTEGER. The first dimension of `b`; $ldb \geq \max(1, n)$.

`ipiv` INTEGER.
Array, DIMENSION at least $\max(1, n)$. The array `ipiv` is an input argument if `fact = 'F'`. It contains details of the interchanges and the block structure of D , as determined by [?hptrf](#).
If `ipiv(i) = k > 0`, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column.
If `uplo = 'U'` and `ipiv(i) = ipiv(i-1) = -m < 0`, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.
If `uplo = 'L'` and `ipiv(i) = ipiv(i+1) = -m < 0`, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

ldx INTEGER. The leading dimension of the output array *x*; $ldx \geq \max(1, n)$.

rwork REAL for `chpsvx`
DOUBLE PRECISION for `zhpsvx`.
Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x COMPLEX for `chpsvx`
DOUBLE COMPLEX for `zhpsvx`.
Array, DIMENSION (*ldx*, *).
If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *x* to the system of equations. The second dimension of *x* must be at least $\max(1, nrhs)$.

afp, ipiv These arrays are output arguments if *fact* = 'N'. See the description of *afp, ipiv* in *Input Arguments* section.

rcond REAL for `chpsvx`
DOUBLE PRECISION for `zhpsvx`.
An estimate of the reciprocal condition number of the matrix *A*. If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr REAL for `chpsvx`
DOUBLE PRECISION for `zhpsvx`.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector *x*(*j*) (the *j*-th column of the solution matrix *x*). If *xtrue* is the true solution corresponding to *x*(*j*), *ferr*(*j*) is an estimated upper bound for the magnitude of the largest element in (*x*(*j*) - *xtrue*) divided by the magnitude of the largest element in *x*(*j*). The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr REAL for `chpsvx`
DOUBLE PRECISION for `zhpsvx`.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector *x*(*j*), that is, the smallest relative change in any element of *A* or *B* that makes *x*(*j*) an exact solution.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.
 If *info* = *i*, and $i = n + 1$, then *D* is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their Fortran 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpsvx` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n^*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>af</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>AF</i> of size $(n^*(n+1)/2)$.
<i>ipiv</i>	Holds the vector of length (n) .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

LAPACK Routines: Least Squares and Eigenvalue Problems

4

This chapter describes the Intel® Math Kernel Library implementation of routines from the LAPACK package that are used for solving linear least squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Sections in this chapter include descriptions of LAPACK [computational routines](#) and [driver routines](#). For full reference on LAPACK routines and related information see [\[LUG\]](#).

Least Squares Problems. A typical *least squares problem* is as follows: given a matrix A and a vector b , find the vector x that minimizes the sum of squares $\sum_i (Ax)_i - b_i)^2$ or, equivalently, find the vector x that minimizes the 2-norm $\|Ax - b\|_2$.

In the most usual case, A is an m -by- n matrix with $m \geq n$ and $\text{rank}(A) = n$. This problem is also referred to as finding the *least squares solution* to an *overdetermined* system of linear equations (here we have more equations than unknowns). To solve this problem, you can use the QR factorization of the matrix A (see [QR Factorization](#)).

If $m < n$ and $\text{rank}(A) = m$, there exist an infinite number of solutions x which exactly satisfy $Ax = b$, and thus minimize the norm $\|Ax - b\|_2$. In this case it is often useful to find the unique solution that minimizes $\|x\|_2$. This problem is referred to as finding the *minimum-norm solution* to an *underdetermined* system of linear equations (here we have more unknowns than equations). To solve this problem, you can use the LQ factorization of the matrix A (see [LQ Factorization](#)).

In the general case you may have a *rank-deficient least squares problem*, with $\text{rank}(A) < \min(m, n)$: find the *minimum-norm least squares solution* that minimizes both $\|x\|_2$ and $\|Ax - b\|_2^2$. In this case (or when the rank of A is in doubt) you can use the QR factorization with pivoting or *singular value decomposition* (see [Singular Value Decomposition](#)).

Eigenvalue Problems. The eigenvalue problems (from German *eigen* "own") are stated as follows: given a matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

If A is a real symmetric or complex Hermitian matrix, the above two equations are equivalent, and the problem is called a *symmetric eigenvalue problem*. Routines for solving this type of problems are described in the section [Symmetric Eigenvalue Problems](#).

Routines for solving eigenvalue problems with nonsymmetric or non-Hermitian matrices are described in the section [Nonsymmetric Eigenvalue Problems](#).

The library also includes routines that handle *generalized symmetric-definite eigenvalue problems*: find the eigenvalues λ and the corresponding eigenvectors x that satisfy one of the following equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is symmetric or Hermitian, and B is symmetric positive-definite or Hermitian positive-definite. Routines for reducing these problems to standard symmetric eigenvalue problems are described in the section [Generalized Symmetric-Definite Eigenvalue Problems](#).

To solve a particular problem, you usually call several computational routines. Sometimes you need to combine the routines of this chapter with other LAPACK routines described in Chapter 3 as well as with BLAS routines described in Chapter 2.

For example, to solve a set of least squares problems minimizing $\|Ax - b\|^2$ for all columns b of a given matrix B (where A and B are real matrices), you can call `?geqrf` to form the factorization $A = QR$, then call `?ormqr` to compute $C = Q^H B$ and finally call the BLAS routine `?trsm` to solve for X the system of equations $RX = C$.

Another way is to call an appropriate driver routine that performs several tasks in one call. For example, to solve the least squares problem the driver routine `?gels` can be used.

WARNING. LAPACK routines require that input matrices do not contain `INF` or `NaN` values. When input data is inappropriate for LAPACK, problems may arise, including possible hangs.

Starting from release 8.0, Intel MKL along with Fortran 77 interface to LAPACK computational and driver routines supports also Fortran 95 interface which uses simplified routine calls with shorter argument lists. The calling sequence for Fortran 95 interface is given in the syntax section of the routine description immediately after Fortran 77 calls.

Routine Naming Conventions

For each routine in this chapter, when calling it from the Fortran 77 program you can use the LAPACK name.

LAPACK names have the structure `xyyzzz`, which is described below.

The initial letter `x` indicates the data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision

The second and third letters *yy* indicate the matrix type and storage scheme:

bd	bidiagonal matrix
ge	general matrix
gb	general band matrix
hs	upper Hessenberg matrix
or	(real) orthogonal matrix
op	(real) orthogonal matrix (packed storage)
un	(complex) unitary matrix
up	(complex) unitary matrix (packed storage)
pt	symmetric or Hermitian positive-definite tridiagonal matrix
sy	symmetric matrix
sp	symmetric matrix (packed storage)
sb	(real) symmetric band matrix
st	(real) symmetric tridiagonal matrix
he	Hermitian matrix
hp	Hermitian matrix (packed storage)
hb	(complex) Hermitian band matrix
tr	triangular or quasi-triangular matrix.

The last three letters *zzz* indicate the computation performed, for example:

qrf	form the QR factorization
lqf	form the LQ factorization.

Thus, the routine `sgeqrf` forms the QR factorization of general real matrices in single precision; the corresponding routine for complex matrices is `cgeqrf`.

Names of the LAPACK computational and driver routines for Fortran 95 interface in Intel MKL are the same as Fortran 77 names but without the first letter that indicates the data type. For example, the name of the routine that forms the QR factorization of general real matrices in Fortran 95 interface is `geqrf`. Handling of different data types is done through defining a specific internal parameter referring to a module block with named constants for single and double precision.

For details on the design of Fortran 95 interface for LAPACK computational and driver routines in Intel MKL and for the general information on how the optional arguments are reconstructed, see [Fortran 95 Interface Conventions](#) in chapter 3 .

Matrix Storage Schemes

LAPACK routines use the following matrix storage schemes:

- *Full storage*: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: an m -by- n band matrix with kl sub-diagonals and ku super-diagonals is stored compactly in a two-dimensional array ab with $kl+ku+1$ rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

In Chapters 3 and 4, arrays that hold matrices in packed storage have names ending in p ; arrays with matrices in band storage have names ending in b . For more information on matrix storage schemes, see “[Matrix Arguments](#)” in Appendix B.

Mathematical Notation

In addition to the mathematical notation used in previous chapters, descriptions of routines in this chapter use the following notation:

λ_i	<i>Eigenvalues</i> of the matrix A (for the definition of eigenvalues, see Eigenvalue Problems).
σ_i	<i>Singular values</i> of the matrix A . They are equal to square roots of the eigenvalues of $A^H A$. (For more information, see Singular Value Decomposition).
$\ x\ _2$	The <i>2-norm</i> of the vector x : $\ x\ _2 = (\sum_i x_i ^2)^{1/2} = \ x\ _E$.
$\ A\ _2$	The <i>2-norm</i> (or <i>spectral norm</i>) of the matrix A . $\ A\ _2 = \max_i \sigma_i$, $\ A\ _2^2 = \max_{\ x\ =1} (Ax \cdot Ax)$.
$\ A\ _E$	The <i>Euclidean norm</i> of the matrix A : $\ A\ _E^2 = \sum_i \sum_j a_{ij} ^2$ (for vectors, the Euclidean norm and the 2-norm are equal: $\ x\ _E = \ x\ _2$).
$q(x, y)$	The <i>acute angle between vectors</i> x and y : $\cos q(x, y) = x \cdot y / (\ x\ _2 \ y\ _2)$.

Computational Routines

In the sections that follow, the descriptions of LAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

Orthogonal Factorizations

Singular Value Decomposition

Symmetric Eigenvalue Problems

Generalized Symmetric-Definite Eigenvalue Problems

Nonsymmetric Eigenvalue Problems

Generalized Nonsymmetric Eigenvalue Problems

Generalized Singular Value Decomposition

See also the respective [driver routines](#).

Orthogonal Factorizations

This section describes the LAPACK routines for the QR (RQ) and LQ (QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included.

QR Factorization. Assume that A is an m -by- n matrix to be factored.

If $m \geq n$, the QR factorization is given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix} = (Q_1, Q_2) \begin{pmatrix} R \\ 0 \end{pmatrix}$$

where R is an n -by- n upper triangular matrix with real diagonal elements, and Q is an m -by- m orthogonal (or unitary) matrix.

You can use the QR factorization for solving the following least squares problem: minimize $\|Ax - b\|^2$ where A is a full-rank m -by- n matrix ($m \geq n$). After factoring the matrix, compute the solution x by solving $Rx = (Q_1)^T b$.

If $m < n$, the QR factorization is given by

$$A = QR = Q(R_1 R_2)$$

where R is trapezoidal, R_1 is upper triangular and R_2 is rectangular.

The LAPACK routines do not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

LQ Factorization LQ factorization of an m -by- n matrix A is as follows. If $m \leq n$,

$$A = (L, 0) Q = (L, 0) \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = (LQ1)$$

where L is an m -by- m lower triangular matrix with real diagonal elements, and Q is an n -by- n orthogonal (or unitary) matrix.

If $m > n$, the LQ factorization is

$$A = \begin{pmatrix} L_1 \\ L_2 \end{pmatrix} Q$$

where L_1 is an n -by- n lower triangular matrix, L_2 is rectangular, and Q is an n -by- n orthogonal (or unitary) matrix.

You can use the LQ factorization to find the minimum-norm solution of an underdetermined system of linear equations $Ax = b$ where A is an m -by- n matrix of rank m ($m < n$). After factoring the matrix, compute the solution vector x as follows: solve $L_1 y = b$ for y , and then compute $x = (Q_1)^H y$.

[Table 4-1](#) lists LAPACK routines (Fortran 77 interface) that perform orthogonal factorization of matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

?geqrf

Computes the QR factorization of a general *m*-by-*n* matrix.

Syntax

FORTRAN 77:

```
call sgeqrf(m, n, a, lda, tau, work, lwork, info)
call dgeqrf(m, n, a, lda, tau, work, lwork, info)
call cgeqrf(m, n, a, lda, tau, work, lwork, info)
call zgeqrf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call geqrf(a [, tau] [,info])
```

Description

The routine forms the *QR* factorization of a general *m*-by-*n* matrix *A* (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix *Q* explicitly. Instead, *Q* is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with *Q* in this representation.

Input Parameters

<i>m</i>	INTEGER. The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i> , <i>work</i>	REAL for <code>sgeqrf</code> DOUBLE PRECISION for <code>dgeqrf</code> COMPLEX for <code>cgeqrf</code> DOUBLE COMPLEX for <code>zgeqrf</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary matrix <i>Q</i> , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix <i>R</i> . If $m < n$, the strictly lower triangular part is overwritten by the details of the unitary matrix <i>Q</i> , and the remaining elements are overwritten by the corresponding elements of the <i>m</i> -by- <i>n</i> upper trapezoidal matrix <i>R</i> .
<i>tau</i>	REAL for <code>sgeqrf</code> DOUBLE PRECISION for <code>dgeqrf</code> COMPLEX for <code>cgeqrf</code> DOUBLE COMPLEX for <code>zgeqrf</code> . Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix <i>Q</i> .

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *geqrf* interface are the following:

a Holds the matrix *A* of size (*m*,*n*).

tau Holds the vector of length min(*m*,*n*)

Application Notes

For better performance, try using *lwork* = *n***blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{aligned} (4/3)n^3 & \quad \text{if } m = n, \\ (2/3)n^2(3m-n) & \quad \text{if } m > n, \\ (2/3)m^2(3n-m) & \quad \text{if } m < n. \end{aligned}$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

`?geqrf` (this routine) to factorize $A = QR$;
`?ormqr` to compute $C = Q^T * B$ (for real matrices);
`?unmqr` to compute $C = Q^H * B$ (for complex matrices);
`?trsm` (a BLAS routine) to solve $R^*X = C$.

(The columns of the computed x are the least squares solution vectors x .)

To compute the elements of Q explicitly, call

`?orgqr` (for real matrices)
`?ungqr` (for complex matrices).

?geqpf

Computes the QR factorization of a general m -by- n matrix with pivoting.

Syntax

FORTRAN 77:

```
call sgeqpf(m, n, a, lda, jpvt, tau, work, info)
call dgeqpf(m, n, a, lda, jpvt, tau, work, info)
call cgeqpf(m, n, a, lda, jpvt, tau, work, rwork, info)
call zgeqpf(m, n, a, lda, jpvt, tau, work, rwork, info)
```

Fortran 95:

```
call geqpf(a, jpvt [,tau] [,info])
```

Description

This routine is deprecated and has been replaced by routine `?geqp3`.

The routine `?geqpf` forms the QR factorization of a general m -by- n matrix A with column pivoting: $A^*P = Q^*R$ (see [Orthogonal Factorizations](#)). Here P denotes an n -by- n permutation matrix.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgeqpf</code> DOUBLE PRECISION for <code>dgeqpf</code> COMPLEX for <code>cgeqpf</code> DOUBLE COMPLEX for <code>zgeqpf</code> . Arrays: $a(la,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$. $work(lwork)$ is a workspace array. The size of the $work$ array must be at least $\max(1, 3*n)$ for real flavors and at least $\max(1, n)$ for complex flavors.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$jpvt$	INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if $jpvt(i) > 0$, the i -th column of A is moved to the beginning of A^*P before the computation, and fixed in place during the computation. If $jpvt(i) = 0$, the i th column of A is a free column (that is, it may be interchanged during the computation with any other free column).
$rwork$	REAL for <code>cgeqpf</code> DOUBLE PRECISION for <code>zgeqpf</code> . A workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

a	Overwritten by the factorization data as follows:

If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary (orthogonal) matrix Q , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix R .

If $m < n$, the strictly lower triangular part is overwritten by the details of the matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix R .

tau REAL for sgeqpf
 DOUBLE PRECISION for dgeqpf
 COMPLEX for cgeqpf
 DOUBLE COMPLEX for zgeqpf.

Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix Q .

jpvt Overwritten by details of the permutation matrix P in the factorization $A*P = Q*R$. More precisely, the columns of $A*P$ are the columns of A in the following order:
 $jpvt(1), jpvt(2), \dots, jpvt(n)$.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqpf` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>jpvt</i>	Holds the vector of length (n) .
<i>tau</i>	Holds the vector of length $\min(m, n)$

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{aligned} (4/3)n^3 & \quad \text{if } m = n, \\ (2/3)n^2(3m-n) & \quad \text{if } m > n, \\ (2/3)m^2(3n-m) & \quad \text{if } m < n. \end{aligned}$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

`?geqpf` (this routine) to factorize $A^*P = Q^*R$;
`?ormqr` to compute $C = Q^T * B$ (for real matrices);
`?unmqr` to compute $C = Q^H * B$ (for complex matrices);
`?trsm` (a BLAS routine) to solve $R^*X = C$.

(The columns of the computed x are the permuted least squares solution vectors x ; the output array `jpvt` specifies the permutation order.)

To compute the elements of Q explicitly, call

`?orgqr` (for real matrices)
`?ungqr` (for complex matrices).

?geqp3

Computes the QR factorization of a general m -by- n matrix with column pivoting using level 3 BLAS.

Syntax

FORTRAN 77:

```
call sgeqp3(m, n, a, lda, jpvt, tau, work, lwork, info)
call dgeqp3(m, n, a, lda, jpvt, tau, work, lwork, info)
call cgeqp3(m, n, a, lda, jpvt, tau, work, lwork, rwork, info)
call zgeqp3(m, n, a, lda, jpvt, tau, work, lwork, rwork, info)
```

Fortran 95:

```
call geqp3(a, jpvt [,tau] [,info])
```

Description

The routine forms the QR factorization of a general m -by- n matrix A with column pivoting: $A^*P = Q^*R$ (see [Orthogonal Factorizations](#)) using Level 3 BLAS. Here P denotes an n -by- n permutation matrix. Use this routine instead of `?geqp3` for better performance.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgeqp3</code> DOUBLE PRECISION for <code>dgeqp3</code> COMPLEX for <code>cgeqp3</code> DOUBLE COMPLEX for <code>zgeqp3</code> . Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; must be at least $\max(1, 3*n+1)$ for real flavors, and at least $\max(1, n+1)$ for complex flavors. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See Application Notes below for details.
$jpvt$	INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if $jpvt(i) \neq 0$, the i -th column of A is moved to the beginning of AP before the computation, and fixed in place during the computation.

If $jpvt(i) = 0$, the i -th column of A is a free column (that is, it may be interchanged during the computation with any other free column).

rwork

REAL for cgeqp3

DOUBLE PRECISION for zgeqp3.

A workspace array, DIMENSION at least $\max(1, 2*n)$. Used in complex flavors only.

Output Parameters

a

Overwritten by the factorization data as follows:

If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary (orthogonal) matrix Q , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix R .

If $m < n$, the strictly lower triangular part is overwritten by the details of the matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix R .

tau

REAL for sgeqp3

DOUBLE PRECISION for dgeqp3

COMPLEX for cgeqp3

DOUBLE COMPLEX for zgeqp3.

Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .

jpvt

Overwritten by details of the permutation matrix P in the factorization $A*P = Q*R$. More precisely, the columns of AP are the columns of A in the following order:

$jpvt(1), jpvt(2), \dots, jpvt(n)$.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqp3` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>jpvt</code>	Holds the vector of length (n) .
<code>tau</code>	Holds the vector of length $\min(m, n)$

Application Notes

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

<code>?geqp3</code> (this routine)	to factorize $A^*P = Q^*R$;
<code>?ormqr</code>	to compute $C = Q^T * B$ (for real matrices);
<code>?unmqr</code>	to compute $C = Q^H * B$ (for complex matrices);
<code>?trsm</code> (a BLAS routine)	to solve $R^*X = C$.

(The columns of the computed x are the permuted least squares solution vectors x ; the output array `jpvt` specifies the permutation order.)

To compute the elements of Q explicitly, call

<code>?orgqr</code>	(for real matrices)
<code>?ungqr</code>	(for complex matrices).

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?orgqr

Generates the real orthogonal matrix Q of the QR factorization formed by ?geqrf.

Syntax

FORTRAN 77:

```
call sorgqr(m, n, k, a, lda, tau, work, lwork, info)
call dorgqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgqr(a, tau [,info])
```

Description

The routine generates the whole or part of m -by- m orthogonal matrix Q of the QR factorization formed by the routines [sgeqrf/dgeqrf](#) or [sgeqpf/dgeqpf](#). Use this routine after a call to [sgeqrf/dgeqrf](#) or [sgeqpf/dgeqpf](#).

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
call ?orgqr(m, m, p, a, lda, tau, work, lwork, info)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
call ?orgqr(m, p, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the QR factorization of leading k columns of the matrix A :

```
call ?orgqr(m, m, k, a, lda, tau, work, lwork, info)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by leading k columns of the matrix A):

```
call ?orgqr(m, k, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m	INTEGER. The order of the orthogonal matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of Q to be computed

$(0 \leq n \leq m)$.

k INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).

a, *tau*, *work* REAL for sorgqr
DOUBLE PRECISION for dorgqr

Arrays:
a(*lda*,*) and *tau*(*) are the arrays returned by sgeqrf / dgeqrf or sgeqpf / dgeqpf.
The second dimension of *a* must be at least $\max(1, n)$.
The dimension of *tau* must be at least $\max(1, k)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array ($lwork \geq n$).
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by *n* leading columns of the *m*-by-*m* orthogonal matrix Q .

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgqr` interface are the following:

a Holds the matrix *A* of size (m, n) .
tau Holds the vector of length (k)

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed *Q* differs from an exactly orthogonal matrix by a matrix *E* such that

$$\|E\|_2 = O(\epsilon) \|A\|_2 \text{ where } \epsilon \text{ is the machine precision.}$$

The total number of floating-point operations is approximately $4 * m * n * k - 2 * (m + n) * k^2 + (4/3) * k^3$.

If $n = k$, the number is approximately $(2/3) * n^2 * (3m - n)$.

The complex counterpart of this routine is [?ungqr](#).

?ormqr

Multiplies a real matrix by the orthogonal matrix Q of the QR factorization formed by ?geqrf or ?geqpf.

Syntax

FORTRAN 77:

```
call sormqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormqr(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the QR factorization formed by the routines [sgeqrf/dgeqrf](#) or [sgeqpf/dgeqpf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (overwriting the result on C).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.

<i>a</i> , <i>tau</i> , <i>c</i> , <i>work</i>	REAL for <i>sgeqrf</i> DOUBLE PRECISION for <i>dgeqrf</i>. Arrays: <i>a</i>(<i>lda</i>,*) and <i>tau</i>(*) are the arrays returned by <i>sgeqrf</i> / <i>dgeqrf</i> or <i>sgeqpf</i> / <i>dgeqpf</i>. The second dimension of <i>a</i> must be at least $\max(1, k)$. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i>(<i>ldc</i>,*) contains the matrix <i>c</i>. The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>. Constraints: <i>lda</i> $\geq \max(1, m)$ if <i>side</i> = 'L'; <i>lda</i> $\geq \max(1, n)$ if <i>side</i> = 'R'.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i>. Constraint: <i>ldc</i> $\geq \max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: <i>lwork</i> $\geq \max(1, n)$ if <i>side</i> = 'L'; <i>lwork</i> $\geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , $Q^T C$, C^*Q , or C^*Q^T (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormqr` interface are the following:

<code>a</code>	Holds the matrix A of size (r,k) . $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m,n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmqr](#).

?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by ?geqrf.

Syntax

FORTRAN 77:

```
call cungqr(m, n, k, a, lda, tau, work, lwork, info)
call zungqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungqr(a, tau [,info])
```

Description

The routine generates the whole or part of m -by- m unitary matrix Q of the QR factorization formed by the routines [cgeqrf/zgeqrf](#) or [cgeqpz/zgeqpz](#). Use this routine after a call to [cgeqrf/zgeqrf](#) or [cgeqpz/zgeqpz](#).

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
call ?ungqr(m, m, p, a, lda, tau, work, lwork, info)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
call ?ungqr(m, p, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the QR factorization of the leading k columns of the matrix A :

```
call ?ungqr(m, m, k, a, lda, tau, work, lwork, info)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by the leading k columns of the matrix A):

```
call ?ungqr(m, k, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m	INTEGER. The order of the unitary matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of Q to be computed

	$(0 \leq n \leq m)$.
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).
$a, \tau, work$	COMPLEX for <code>cungqr</code> DOUBLE COMPLEX for <code>zungqr</code> Arrays: $a(lda,*)$ and $\tau(*)$ are the arrays returned by <code>cgeqrf/zgeqrf</code> or <code>cgeqpz/zgeqpz</code> . The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array ($lwork \geq n$). If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

a	Overwritten by n leading columns of the m -by- m unitary matrix Q .
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungqr` interface are the following:

a	Holds the matrix A of size (m, n) .

tau Holds the vector of length (*k*).

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $16 * m * n * k - 8 * (m + n) * k^2 + (16/3) * k^3$.

If $n = k$, the number is approximately $(8/3) * n^2 * (3m - n)$.

The real counterpart of this routine is [?orgqr](#).

?unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by ?geqrf.

Syntax

FORTRAN 77:

```
call cunmqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmqr(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a rectangular complex matrix c by Q or Q_H , where Q is the unitary matrix Q of the QR factorization formed by the routines [cgeqrf/zgeqrf](#) or [cgeqpf/zgeqpf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^H * C$, $C * Q$, or $C * Q^H$ (overwriting the result on c).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q_H is applied to c from the left. If <i>side</i> = 'R', Q or Q_H is applied to c from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies c by Q. If <i>trans</i> = 'C', the routine multiplies c by Q^H.
<i>m</i>	INTEGER. The number of rows in the matrix c ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in c ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a, c, tau, work</i>	COMPLEX for cgeqrf DOUBLE COMPLEX for zgeqrf. Arrays: $a(la,*)$ and $tau(*)$ are the arrays returned by cgeqrf / zgeqrf or cgeqpf / zgeqpf. The second dimension of a must be at least $\max(1, k)$. The dimension of tau must be at least $\max(1, k)$. $c ldc,*)$ contains the matrix c. The second dimension of c must be at least $\max(1, n)$ $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a. Constraints:

$lda \geq \max(1, m)$ if $side = 'L'$;
 $lda \geq \max(1, n)$ if $side = 'R'$.
 ldc INTEGER. The first dimension of c . Constraint:
 $ldc \geq \max(1, m)$.
 $lwork$ INTEGER. The size of the $work$ array. Constraints:
 $lwork \geq \max(1, n)$ if $side = 'L'$;
 $lwork \geq \max(1, m)$ if $side = 'R'$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application notes* for the suggested value of $lwork$.

Output Parameters

c Overwritten by the product Q^*C , $Q^H C$, C^*Q , or C^*Q^H (as specified by $side$ and $trans$).
 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
 $info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmqr` interface are the following:

a Holds the matrix A of size (r, k) .
 $r = m$ if $side = 'L'$.
 $r = n$ if $side = 'R'$.
 tau Holds the vector of length (k) .
 c Holds the matrix C of size (m, n) .

<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if $side = 'L'$) or $lwork = m * blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormqr](#).

?gelqf

Computes the LQ factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgelqf(m, n, a, lda, tau, work, lwork, info)
call dgelqf(m, n, a, lda, tau, work, lwork, info)
call cgelqf(m, n, a, lda, tau, work, lwork, info)
call zgelqf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gelqf(a [, tau] [,info])
```

Description

The routine forms the LQ factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for `sgelqf`
 DOUBLE PRECISION for `dgelqf`
 COMPLEX for `cgelqf`
 DOUBLE COMPLEX for `zgelqf`.
Arrays:
 $a(lda,*)$ contains the matrix A .
 The second dimension of a must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

$lwork$ INTEGER. The size of the $work$ array; at least $\max(1, m)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the factorization data as follows:
 If $m \leq n$, the elements above the diagonal are overwritten by the details of the unitary (orthogonal) matrix Q , and the lower triangle is overwritten by the corresponding elements of the lower triangular matrix L .

If $m > n$, the strictly upper triangular part is overwritten by the details of the matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n lower trapezoidal matrix L .

<i>tau</i>	REAL for <code>sgelqf</code> DOUBLE PRECISION for <code>dgelqf</code> COMPLEX for <code>cgelqf</code> DOUBLE COMPLEX for <code>zgelqf</code>. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix Q.
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelqf` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>tau</i>	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using $lwork = m * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{aligned} (4/3)n^3 & \quad \text{if } m = n, \\ (2/3)n^2(3m-n) & \quad \text{if } m > n, \\ (2/3)m^2(3n-m) & \quad \text{if } m < n. \end{aligned}$$

The number of operations for complex flavors is 4 times greater.

To find the minimum-norm solution of an underdetermined least squares problem minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

`?gelqf` (this routine) to factorize $A = L^*Q$;

`?trsm` (a BLAS routine) to solve $L^*Y = B$ for Y ;

`?ormlq` to compute $X = (Q_1)^T * Y$ (for real matrices);

`?unmlq` to compute $X = (Q_1)^H * Y$ (for complex matrices).

(The columns of the computed X are the minimum-norm solution vectors x . Here A is an m -by- n matrix with $m < n$; Q_1 denotes the first m columns of Q).

To compute the elements of Q explicitly, call

`?orglq` (for real matrices)

`?unglq` (for complex matrices).

?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call sorglq(m, n, k, a, lda, tau, work, lwork, info)
call dorglq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orglq(a, tau [,info])
```

Description

The routine generates the whole or part of n -by- n orthogonal matrix Q of the LQ factorization formed by the routines [sgelqf](#)/[gelqf](#). Use this routine after a call to [sgelqf](#)/[dgelqf](#).

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n \geq p$. To compute the whole matrix Q , use:

```
call ?orglq(n, n, p, a, lda, tau, work, lwork, info)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
call ?orglq(p, n, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the LQ factorization of A 's leading k rows, use:

```
call ?orglq(n, n, k, a, lda, tau, work, lwork, info)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by A 's leading k rows, use:

```
call ?orgqr(k, n, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m INTEGER. The number of rows of Q to be computed
($0 \leq m \leq n$).

n INTEGER. The order of the orthogonal matrix Q ($n \geq m$).

<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$).
<i>a</i> , <i>tau</i> , <i>work</i>	REAL for <code>sorglq</code> DOUBLE PRECISION for <code>dorglq</code> Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are the arrays returned by <code>sgelqf/dgelqf</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; at least $\max(1, m)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by <i>m</i> leading rows of the <i>n</i> -by- <i>n</i> orthogonal matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orglq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).

Application Notes

For better performance, try using $lwork = m * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $4 * m * n * k - 2 * (m + n) * k^2 + (4/3) * k^3$.

If $m = k$, the number is approximately $(2/3) * m^2 * (3n - m)$.

The complex counterpart of this routine is [?unglq](#).

?ormlq

Multiplies a real matrix by the orthogonal matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call sormlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormlq(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the LQ factorization formed by the routine [sgelqf](#)/[dgelqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^T C$, C^*Q , or $C^T Q$ (overwriting the result on C).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	REAL for sormlq DOUBLE PRECISION for dormlq . Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are arrays returned by ?gelqf . The second dimension of <i>a</i> must be: at least $\max(1, m)$ if <i>side</i> = 'L'; at least $\max(1, n)$ if <i>side</i> = 'R'. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c Overwritten by the product Q^*C , $Q^T * C$, C^*Q , or C^*Q^T (as specified by *side* and *trans*).

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormlq` interface are the following:

a Holds the matrix *A* of size (*k*,*m*).

tau Holds the vector of length (*k*).

c Holds the matrix *C* of size (*m*,*n*).

side Must be 'L' or 'R'. The default value is 'L'.

trans Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if $side = 'L'$) or $lwork = m * blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmlq](#).

?unglq

Generates the complex unitary matrix Q of the LQ factorization formed by [?gelqf](#).

Syntax

FORTRAN 77:

```
call cunqlq(m, n, k, a, lda, tau, work, lwork, info)
call zunqlq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call unqlq(a, tau [,info])
```

Description

The routine generates the whole or part of n -by- n unitary matrix Q of the LQ factorization formed by the routines [cgelqf](#)/[zgelqf](#). Use this routine after a call to [cgelqf](#)/[zgelqf](#).

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n < p$. To compute the whole matrix Q , use:

```
call ?unglq(n, n, p, a, lda, tau, work, lwork, info)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
call ?unglq(p, n, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the LQ factorization of the leading k rows of the matrix A , use:

```
call ?unglq(n, n, k, a, lda, tau, work, lwork, info)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by the leading k rows of the matrix A , use:

```
call ?ungqr(k, n, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m	INTEGER. The number of rows of Q to be computed ($0 \leq m \leq n$).
n	INTEGER. The order of the unitary matrix Q ($n \geq m$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$).
$a, \tau, work$	COMPLEX for <code>cunglq</code> DOUBLE COMPLEX for <code>zunglq</code> Arrays: $a(lda,*)$ and $\tau(*)$ are the arrays returned by <code>sgelqf/dgelqf</code> . The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; at least $\max(1, m)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

<i>a</i>	Overwritten by <i>m</i> leading rows of the <i>n</i> -by- <i>n</i> unitary matrix <i>Q</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unglq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).

Application Notes

For better performance, try using *lwork* = *m***blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Q differs from an exactly unitary matrix by a matrix E such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $16 * m * n * k - 8 * (m + n) * k^2 + (16/3) * k^3$.

If $m = k$, the number is approximately $(8/3) * m^2 * (3n - m)$.

The real counterpart of this routine is [?orglq](#).

?unmlq

Multiplies a complex matrix by the unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call cunmlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmlq(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a real m -by- n matrix C by Q or Q^H , where Q is the unitary matrix Q of the LQ factorization formed by the routine [cgelqf/zgelqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q * C$, $Q^H * C$, $C * Q$, or $C * Q^H$ (overwriting the result on C).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q_H .

m INTEGER. The number of rows in the matrix C ($m \geq 0$).
 n INTEGER. The number of columns in C ($n \geq 0$).
 k INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:
 $0 \leq k \leq m$ if $side = 'L'$;
 $0 \leq k \leq n$ if $side = 'R'$.
 $a, c, tau, work$ COMPLEX for `cunmlq`
DOUBLE COMPLEX for `zunmlq`.
Arrays:
 $a(lda,*)$ and $tau(*)$ are arrays returned by `?gelqf`.
The second dimension of a must be:
at least $\max(1, m)$ if $side = 'L'$;
at least $\max(1, n)$ if $side = 'R'$.
The dimension of tau must be at least $\max(1, k)$.
 $c(ldc,*)$ contains the matrix C .
The second dimension of c must be at least $\max(1, n)$
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
 lda INTEGER. The first dimension of a ; $lda \geq \max(1, k)$.
 ldc INTEGER. The first dimension of c ; $ldc \geq \max(1, m)$.
 $lwork$ INTEGER. The size of the $work$ array. Constraints:
 $lwork \geq \max(1, n)$ if $side = 'L'$;
 $lwork \geq \max(1, m)$ if $side = 'R'$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c Overwritten by the product Q^*C , $Q^H * C$, C^*Q , or C^*Q^H (as specified by $side$ and $trans$).

<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmlq` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>m</i>).
<code>tau</code>	Holds the vector of length (<i>k</i>).
<code>c</code>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormlq](#).

?geqlf

Computes the QL factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgeqlf(m, n, a, lda, tau, work, lwork, info)
call dgeqlf(m, n, a, lda, tau, work, lwork, info)
call cgeqlf(m, n, a, lda, tau, work, lwork, info)
call zgeqlf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call geqlf(a [, tau] [,info])
```

Description

The routine forms the QL factorization of a general m -by- n matrix A . No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for sgeqlf DOUBLE PRECISION for dgeqlf COMPLEX for cgeqlf DOUBLE COMPLEX for zgeqlf. Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; at least $\max(1, n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a	Overwritten on exit by the factorization data as follows: if $m \geq n$, the lower triangle of the subarray $a(m-n+1:m, 1:n)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; in both cases, the remaining elements, with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.
tau	REAL for sgeqlf DOUBLE PRECISION for dgeqlf COMPLEX for cgeqlf DOUBLE COMPLEX for zgeqlf. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqlf` interface are the following:

a	Holds the matrix A of size (m, n) .
tau	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using `lwork = n*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

<code>?ungql</code>	to generate matrix Q (for complex matrices);
<code>?ormql</code>	to apply matrix Q (for real matrices);
<code>?unmql</code>	to apply matrix Q (for complex matrices).

?orgql

Generates the real matrix Q of the QL factorization formed by ?geqlf.

Syntax

FORTRAN 77:

```
call sorgql(m, n, k, a, lda, tau, work, lwork, info)
call dorgql(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgql(a, tau [,info])
```

Description

The routine generates an m -by- n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors $H(i)$ of order m : $Q = H(k) * \dots * H(2) * H(1)$ as returned by the routines [sgeqlf/dgeqlf](#). Use this routine after a call to [sgeqlf/dgeqlf](#).

Input Parameters

m	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of the matrix Q ($m \geq n \geq 0$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
$a, \tau, work$	REAL for sorgql DOUBLE PRECISION for dorgql Arrays: $a(lda,*)$, $\tau(*)$. On entry, the $(n - k + i)$th column of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by sgeqlf/dgeqlf in the last k columns of its array argument a; $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by sgeqlf/dgeqlf; The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; at least $\max(1, n)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla. See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

<i>a</i>	Overwritten by the m -by- n matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgql` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>tau</i>	Holds the vector of length (k) .

Application Notes

For better performance, try using *lwork* = $n \times \text{blocksize}$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?ungql](#).

?ungql

Generates the complex matrix Q of the QL factorization formed by ?geqlf.

Syntax

FORTRAN 77:

```
call cungql(m, n, k, a, lda, tau, work, lwork, info)
call zungql(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungql(a, tau [,info])
```

Description

The routine generates an m -by- n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors $H(i)$ of order m : $Q = H(k) * \dots * H(2) * H(1)$ as returned by the routines [cgeqlf/zgeqlf](#). Use this routine after a call to [cgeqlf/zgeqlf](#).

Input Parameters

m	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of the matrix Q ($m \geq n \geq 0$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
$a, \tau, work$	COMPLEX for cungql DOUBLE COMPLEX for zungql Arrays: $a(lda,*)$, $\tau(*)$, $work(lwork)$. On entry, the $(n - k + i)$th column of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by cgeqlf/zgeqlf in the last k columns of its array argument a; $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by cgeqlf/zgeqlf;

The second dimension of a must be at least $\max(1, n)$.
 The dimension of τ must be at least $\max(1, k)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda INTEGER. The first dimension of a ; at least $\max(1, m)$.
lwork INTEGER. The size of the $work$ array; at least $\max(1, n)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the m -by- n matrix Q .
 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungql` interface are the following:

a Holds the matrix A of size (m, n) .
 τ Holds the vector of length (k) .

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?orgql](#).

?ormql

Multiplies a real matrix by the orthogonal matrix Q of the QL factorization formed by ?geqlf.

Syntax

FORTRAN 77:

```
call sormql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormql(a, tau, c [,side] [,trans] [,info])
```

Description

This routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the QL factorization formed by the routine [sgeqlf/dgeqlf](#).

Depending on the parameters `side` and `trans`, the routine [?ormql](#) can form one of the matrix products Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (overwriting the result over C).

Input Parameters

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side = 'L'</code> , Q or Q^T is applied to C from the left. If <code>side = 'R'</code> , Q or Q^T is applied to C from the right.
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'T'.

If *trans* = 'N', the routine multiplies *c* by Q .
 If *trans* = 'T', the routine multiplies *c* by Q^T .

m INTEGER. The number of rows in the matrix *c* ($m \geq 0$).

n INTEGER. The number of columns in *c* ($n \geq 0$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:
 $0 \leq k \leq m$ if *side* = 'L';
 $0 \leq k \leq n$ if *side* = 'R'.

a, *tau*, *c*, *work* REAL for sormql
 DOUBLE PRECISION for dormql.
 Arrays: *a*(*lda*,*), *tau*(*), *c*(*ldc*,*).
 On entry, the *i*th column of *a* must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by sgeqlf/dgeqlf in the last *k* columns of its array argument *a*.
 The second dimension of *a* must be at least $\max(1, k)$.
tau(*i*) must contain the scalar factor of the elementary reflector H_i , as returned by sgeqlf/dgeqlf.
 The dimension of *tau* must be at least $\max(1, k)$.
c(*ldc*,*) contains the *m*-by-*n* matrix *C*.
 The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*;
 if *side* = 'L', $lda \geq \max(1, m)$;
 if *side* = 'R', $lda \geq \max(1, n)$.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.

If `lwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`. See *Application Notes* for the suggested value of `lwork`.

Output Parameters

<code>c</code>	Overwritten by the product Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (as specified by <code>side</code> and <code>trans</code>).
<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormql` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>k</i>). $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length (<i>k</i>).
<code>c</code>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmql](#).

[?unmql](#)

Multiplies a complex matrix by the unitary matrix Q of the QL factorization formed by [?geqlf](#).

Syntax

FORTRAN 77:

```
call cunmql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmql(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a complex m -by- n matrix c by Q or Q^H , where Q is the unitary matrix Q of the QL factorization formed by the routine [cgeqlf/zgeqlf](#).

Depending on the parameters `side` and `trans`, the routine [?unmql](#) can form one of the matrix products $Q^H C$, $Q^H * C$, $C * Q$, or $C * Q^H$ (overwriting the result over c).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to c from the left. If <i>side</i> = 'R', Q or Q^H is applied to c from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies c by Q. If <i>trans</i> = 'C', the routine multiplies c by Q^H.
<i>m</i>	INTEGER. The number of rows in the matrix c ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in c ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a, tau, c, work</i>	COMPLEX for cunmq1 DOUBLE COMPLEX for zunmq1. Arrays: <i>a</i>(<i>lda</i>,*), <i>tau</i>(*), <i>c</i>(<i>ldc</i>,*), <i>work</i>(<i>lwork</i>). On entry, the <i>i</i>-th column of <i>a</i> must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <i>cgeqlf/zgeqlf</i> in the last <i>k</i> columns of its array argument <i>a</i>. The second dimension of <i>a</i> must be at least $\max(1, k)$. <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by <i>cgeqlf/zgeqlf</i>. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i>(<i>ldc</i>,*) contains the <i>m</i>-by-<i>n</i> matrix C. The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`. See *Application Notes* for the suggested value of `lwork`.

Output Parameters

<code>c</code>	Overwritten by the product Q^*C , $Q^H C$, C^*Q , or C^*Q^H (as specified by <code>side</code> and <code>trans</code>).
<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmql` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size (r, k) . $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix <i>C</i> of size (m, n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormql](#).

?gerqf

Computes the RQ factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgerqf(m, n, a, lda, tau, work, lwork, info)
call dgerqf(m, n, a, lda, tau, work, lwork, info)
call cgerqf(m, n, a, lda, tau, work, lwork, info)
call zgerqf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gerqf(a [, tau] [,info])
```

Description

The routine forms the RQ factorization of a general m -by- n matrix A . No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for sgerqf DOUBLE PRECISION for dgerqf COMPLEX for cgerqf DOUBLE COMPLEX for zgerqf. Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; $lwork \geq \max(1, m)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla. See Application Notes for the suggested value of $lwork$.

Output Parameters

a	Overwritten on exit by the factorization data as follows: if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ th subdiagonal contain the m -by- n upper trapezoidal matrix R ; in both cases, the remaining elements, with the array tau , represent the orthogonal/unitary matrix Q as a product of $\min(m, n)$ elementary reflectors.
tau	REAL for sgerqf DOUBLE PRECISION for dgerqf COMPLEX for cgerqf DOUBLE COMPLEX for zgerqf.

	Array, <code>DIMENSION</code> at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .
<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gerqf` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>tau</code>	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

<code>?orgrq</code>	to generate matrix Q (for real matrices);
<code>?ungrq</code>	to generate matrix Q (for complex matrices);
<code>?ormrq</code>	to apply matrix Q (for real matrices);
<code>?unmrq</code>	to apply matrix Q (for complex matrices).

?orgrq

Generates the real matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call sorgrq(m, n, k, a, lda, tau, work, lwork, info)
call dorgrq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgrq(a, tau [,info])
```

Description

The routine generates an m -by- n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the routines `sgerqf/dgerqf`. Use this routine after a call to `sgerqf/dgerqf`.

Input Parameters

m	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of the matrix Q ($n \geq m$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
$a, \tau, work$	REAL for <code>sorgrq</code> DOUBLE PRECISION for <code>dorgrq</code> Arrays: $a(lda,*)$, $\tau(*)$.

On entry, the $(m - k + i)$ -th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by `sgerqf/dgerqf` in the last k rows of its array argument a ;

$\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `sgerqf/dgerqf`;

The second dimension of a must be at least $\max(1, n)$.

The dimension of τ must be at least $\max(1, k)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The first dimension of a ; at least $\max(1, m)$.

$lwork$

INTEGER. The size of the $work$ array; at least $\max(1, m)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a

Overwritten by the m -by- n matrix Q .

$work(1)$

If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgrq` interface are the following:

a

Holds the matrix A of size (m, n) .

τ

Holds the vector of length (k) .

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?ungrq](#).

?ungrq

Generates the complex matrix Q of the RQ factorization formed by [?gerqf](#).

Syntax

FORTRAN 77:

```
call cungrq(m, n, k, a, lda, tau, work, lwork, info)
call zungrq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungrq(a, tau [,info])
```

Description

The routine generates an m -by- n complex matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)H^*H(2)H^* \dots H(k)H$ as returned by the routines [sgerqf/dgerqf](#). Use this routine after a call to [sgerqf/dgerqf](#).

Input Parameters

m	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of the matrix Q ($n \geq m$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
$a, \tau, work$	REAL for cungrq DOUBLE PRECISION for zungrq Arrays: $a(lda,*)$, $\tau(*)$, $work(lwork)$. On entry, the $(m - k + i)$th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by sgerqf/dgerqf in the last k rows of its array argument a; $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by sgerqf/dgerqf; The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; at least $\max(1, m)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla. See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

a	Overwritten by the m -by- n matrix Q .

`work(1)` If `info = 0`, on exit `work(1)` contains the minimum value of `lwork` required for optimum performance. Use this `lwork` for subsequent runs.

`info` INTEGER.
 If `info = 0`, the execution is successful.
 If `info = -i`, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungrq` interface are the following:

`a` Holds the matrix *A* of size (*m*, *n*).

`tau` Holds the vector of length (*k*).

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `?orgrq`.

?ormrq

Multiplies a real matrix by the orthogonal matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call sormrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormqr(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors H_i : $Q = H_1 H_2 \dots H_k$ as returned by the RQ factorization routine [sgerqf/dgerqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^T C$, C^*Q , or C^*Q^T (overwriting the result over C).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.

a, *tau*, *c*, *work*

REAL for `sormrq`
DOUBLE PRECISION for `dormrq`.
Arrays: *a*(*lda*,*), *tau*(*), *c*(*ldc*,*).

On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by `sgerqf`/`dgerqf` in the last *k* rows of its array argument *a*.
The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(*i*) must contain the scalar factor of the elementary reflector H_i , as returned by `sgerqf`/`dgerqf`.
The dimension of *tau* must be at least $\max(1, k)$.
c(*ldc*,*) contains the *m*-by-*n* matrix *C*.
The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc

INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork

INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c

Overwritten by the product Q^*C , $Q^T C$, C^*Q , or C^*Q^T (as specified by *side* and *trans*).

work(1)

If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormrq` interface are the following:

<code>a</code>	Holds the matrix A of size (k, m) .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m, n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmrq](#).

zunmrq

Multiplies a complex matrix by the unitary matrix Q of the RQ factorization formed by `zgerqf`.

Syntax

FORTRAN 77:

```
call cunmrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmrq(a, tau, c [,side] [,trans] [,info])
```

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)H^*H(2)H^* \dots H(k)H^*$. H has returned by the RQ factorization routine [cgerqf/zgerqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^H * C$, $C * Q$, or $C * Q^H$ (overwriting the result over C).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.

a, *tau*, *c*, *work*

COMPLEX for cunmrq
DOUBLE COMPLEX for zunmrq.
Arrays: *a*(*lda*,*), *tau*(*), *c*(*ldc*,*), *work*(*lwork*).
On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by cgerqf/zgerqf in the last *k* rows of its array argument *a*.
The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by cgerqf/zgerqf.
The dimension of *tau* must be at least $\max(1, k)$.
c(*ldc*,*) contains the *m*-by-*n* matrix *C*.
The second dimension of *c* must be at least $\max(1, n)$
work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc

INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork

INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c

Overwritten by the product Q^*C , $Q^H * C$, C^*Q , or C^*Q^H (as specified by *side* and *trans*).

work(1)

If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info

INTEGER.
If *info* = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmrq` interface are the following:

<code>a</code>	Holds the matrix A of size (k, m) .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m, n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if $side = 'L'$) or $lwork = m * blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `?ormrq`.

?tzzrf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax

FORTRAN 77:

```
call stzzrf(m, n, a, lda, tau, work, lwork, info)
call dtzzrf(m, n, a, lda, tau, work, lwork, info)
call ctzzrf(m, n, a, lda, tau, work, lwork, info)
call ztzzrf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call tzzrf(a [, tau] [,info])
```

Description

This routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix A to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = (R \ 0) * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

See ?larz that applies an elementary reflector returned by ?tzzrf to a general matrix.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq m$).
$a, work$	REAL for stzzrf DOUBLE PRECISION for dtzzrf COMPLEX for ctzzrf DOUBLE COMPLEX for ztzzrf. Arrays: $a(lda,*)$, $work(lwork)$. The leading m -by- n upper trapezoidal part of the array a contains the matrix A to be factorized.

The second dimension of a must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
 lda INTEGER. The first dimension of a ; at least $\max(1, m)$.
 $lwork$ INTEGER. The size of the $work$ array;
 $lwork \geq \max(1, m)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten on exit by the factorization data as follows:
 the leading m -by- m upper triangular part of a contains the upper triangular matrix R , and elements $m+1$ to n of the first m rows of a , with the array tau , represent the orthogonal matrix Z as a product of m elementary reflectors.

tau REAL for `stzrzf`
 DOUBLE PRECISION for `dtzrzf`
 COMPLEX for `ctzrzf`
 DOUBLE COMPLEX for `ztzrzf`.
 Array, DIMENSION at least $\max(1, m)$. Contains scalar factors of the elementary reflectors for the matrix Z .

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tzrzf` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m,n) .
<i>tau</i>	Holds the vector of length (m) .

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

<code>?ormrz</code>	to apply matrix <i>Q</i> (for real matrices)
<code>?unmrz</code>	to apply matrix <i>Q</i> (for complex matrices).

?ormrz

Multiplies a real matrix by the orthogonal matrix defined from the factorization formed by ?tzzrf.

Syntax

FORTRAN 77:

```
call sormrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
call dormrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormrz(a, tau, c, l [, side] [,trans] [,info])
```

Description

The routine multiplies a real m -by- n matrix c by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the factorization routine `stzrzf/dtzrzf`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (overwriting the result over c).

The matrix Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to c from the left. If <i>side</i> = 'R', Q or Q^T is applied to c from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies c by Q . If <i>trans</i> = 'T', the routine multiplies c by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix c ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in c ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.
<i>l</i>	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder reflectors. Constraints: $0 \leq l \leq m$, if <i>side</i> = 'L'; $0 \leq l \leq n$, if <i>side</i> = 'R'.
<i>a, tau, c, work</i>	REAL for <code>sormrz</code> DOUBLE PRECISION for <code>dormrz</code> . Arrays: $a(lda,*)$, $tau(*)$, $c(ldc,*)$. On entry, the i th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>stzrzf/dtzrzf</code> in the last k rows of its array argument a .

The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by `stzrzf/dtzrzf`.
The dimension of *tau* must be at least $\max(1, k)$.
c(*ldc*,*) contains the *m*-by-*n* matrix *C*.
The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c Overwritten by the product Q^*C , $Q^T * C$, C^*Q , or C^*Q^T (as specified by *side* and *trans*).

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormrz` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (k, m) .
<i>tau</i>	Holds the vector of length (k) .
<i>c</i>	Holds the matrix <i>C</i> of size (m, n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if *side* = 'L') or $lwork = m * blocksize$ (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmrz](#).

[?unmrz](#)

Multiplies a complex matrix by the unitary matrix defined from the factorization formed by [?tzrzf](#).

Syntax

FORTRAN 77:

```
call cunmrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
call zunmrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmrz(a, tau, c, l [,side] [,trans] [,info])
```

Description

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the unitary matrix defined as a product of k elementary reflectors $H(i)$:

$Q = H(1)H^* H(2)H^* \dots H(k)H$ as returned by the factorization routine [ctzrzf/ztrzf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^H C$, C^*Q , or C^*Q^H (overwriting the result over C).

The matrix Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'C', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$, if <i>side</i> = 'L'; $0 \leq k \leq n$, if <i>side</i> = 'R'.
<i>l</i>	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder reflectors. Constraints: $0 \leq l \leq m$, if <i>side</i> = 'L'; $0 \leq l \leq n$, if <i>side</i> = 'R'.
<i>a, tau, c, work</i>	COMPLEX for cunmrz DOUBLE COMPLEX for zunmrz. Arrays: $a(lda,*)$, $tau(*)$, $c ldc,*)$, $work(lwork)$.

On entry, the i th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by `ctzrzf/ztzrzf` in the last k rows of its array argument a .

The second dimension of a must be at least $\max(1, m)$ if $side = 'L'$, and at least $\max(1, n)$ if $side = 'R'$.

$\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `ctzrzf/ztzrzf`.

The dimension of τ must be at least $\max(1, k)$.

$c(ldc,*)$ contains the m -by- n matrix C .

The second dimension of c must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, k)$.

ldc INTEGER. The first dimension of c ; $ldc \geq \max(1, m)$.

$lwork$ INTEGER. The size of the $work$ array. Constraints:

$lwork \geq \max(1, n)$ if $side = 'L'$;

$lwork \geq \max(1, m)$ if $side = 'R'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c Overwritten by the product Q^*C , $Q^H * C$, C^*Q , or C^*Q^H (as specified by $side$ and $trans$).

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmrz` interface are the following:

<code>a</code>	Holds the matrix A of size (k, m) .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m, n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormrz](#).

?ggqrf

Computes the generalized QR factorization of two matrices.

Syntax

FORTRAN 77:

```
call sggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call dggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call cggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call zggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
```

Fortran 95:

```
call ggqrf(a, b [,taua] [,taub] [,info])
```

Description

The routine forms the generalized QR factorization of an n -by- m matrix A and an n -by- p matrix B as $A = Q^*R$, $B = Q^*T^*Z$, where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{matrix} & m \\ & m \\ n - m & \begin{pmatrix} R_{11} \\ 0 \end{pmatrix} \end{matrix}, \quad \text{if } n \geq m$$

or

$$R = \begin{matrix} n & m - n \\ n & \begin{pmatrix} R_{11} & R_{12} \end{pmatrix} \end{matrix}, \quad \text{if } n < m$$

where R_{11} is upper triangular, and

$$T = \begin{matrix} & p-n & n \\ n & \begin{pmatrix} 0 & T_{12} \end{pmatrix} \end{matrix}, \text{ if } n \leq p,$$

$$T = \begin{matrix} & p \\ n-p & \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \end{matrix}, \text{ if } n > p,$$

where T_{12} or T_{21} is a p -by- p upper triangular matrix.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $B^{-1}A$ as:

$$B^{-1} * A = Z^H * (T^{-1} * R)$$

Input Parameters

n	INTEGER. The number of rows of the matrices A and B ($n \geq 0$).
m	INTEGER. The number of columns in A ($m \geq 0$).
p	INTEGER. The number of columns in B ($p \geq 0$).
$a, b, work$	REAL for sggqrf DOUBLE PRECISION for dggqrf COMPLEX for cggqrf DOUBLE COMPLEX for zggqrf. Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, m)$. $b(l db,*)$ contains the matrix B . The second dimension of b must be at least $\max(1, p)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.
ldb	INTEGER. The first dimension of b ; at least $\max(1, n)$.
$lwork$	INTEGER. The size of the $work$ array; must be at least $\max(1, n, m, p)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>a, b</i>	Overwritten by the factorization data as follows: on exit, the elements on and above the diagonal of the array <i>a</i> contain the $\min(n,m)$-by-<i>m</i> upper trapezoidal matrix R (R is upper triangular if $n \geq m$); the elements below the diagonal, with the array <i>taua</i>, represent the orthogonal/unitary matrix Q as a product of $\min(n,m)$ elementary reflectors ; if $n \leq p$, the upper triangle of the subarray <i>b</i>(1:<i>n</i>, <i>p</i>-<i>n</i>+1:<i>p</i>) contains the <i>n</i>-by-<i>n</i> upper triangular matrix T; if $n > p$, the elements on and above the (<i>n</i>-<i>p</i>)th subdiagonal contain the <i>n</i>-by-<i>p</i> upper trapezoidal matrix T; the remaining elements, with the array <i>taub</i>, represent the orthogonal/unitary matrix Z as a product of elementary reflectors.
<i>taua, taub</i>	REAL for sggqrf DOUBLE PRECISION for dggqrf COMPLEX for cggqrf DOUBLE COMPLEX for zggqrf. Arrays, DIMENSION at least $\max(1, \min(n, m))$ for <i>taua</i> and at least $\max(1, \min(n, p))$ for <i>taub</i>. The array <i>taua</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q. The array <i>taub</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z.
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggqrf` interface are the following:

<code>a</code>	Holds the matrix A of size (n, m) .
<code>b</code>	Holds the matrix B of size (n, p) .
<code>taua</code>	Holds the vector of length $\min(n, m)$.
<code>taub</code>	Holds the vector of length $\min(n, p)$.

Application Notes

For better performance, try using $lwork \geq \max(n, m, p) * \max(nb1, nb2, nb3)$, where $nb1$ is the optimal blocksize for the QR factorization of an n -by- m matrix, $nb2$ is the optimal blocksize for the RQ factorization of an n -by- p matrix, and $nb3$ is the optimal blocksize for a call of `?ormqr/?unmqr`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggrqf

Computes the generalized RQ factorization of two matrices.

Syntax

FORTRAN 77:

```

call sggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call dggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call cggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call zggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)

```

Fortran 95:

```

call ggrqf(a, b [,taua] [,taub] [,info])

```

Description

The routine forms the generalized RQ factorization of an m -by- n matrix A and an p -by- n matrix B as $A = R^*Q$, $B = Z^*T^*Q$, where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{matrix} & n-m & m \\ m & \begin{pmatrix} 0 & R_{12} \end{pmatrix} \end{matrix}, \quad \text{if } m \leq n,$$

or

$$R = \begin{matrix} & n \\ m-n & \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix} \\ n & \end{matrix}, \quad \text{if } m > n,$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} n & \\ & p - n \end{pmatrix} \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}, \quad \text{if } p \geq n,$$

or

$$T = \begin{pmatrix} p & n - p \\ & \end{pmatrix} \begin{pmatrix} T_{11} & T_{12} \end{pmatrix}, \quad \text{if } p < n,$$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the *GRQ* factorization of A and B implicitly gives the *RQ* factorization of A^*B^{-1} as:

$$A^*B^{-1} = (R^*T^{-1})^*Z^H$$

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
p	INTEGER. The number of rows in B ($p \geq 0$).
n	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
$a, b, work$	REAL for sggrqf DOUBLE PRECISION for dggrqf COMPLEX for cggrqf DOUBLE COMPLEX for zggrqf. Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the p -by- n matrix B . The second dimension of b must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, p)$.

lwork INTEGER. The size of the *work* array; must be at least $\max(1, n, m, p)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a, b Overwritten by the factorization data as follows:
 on exit, if $m \leq n$, the upper triangle of the subarray *a*(1:*m*, *n-m+1*:*n*) contains the *m*-by-*m* upper triangular matrix *R*;
 if $m > n$, the elements on and above the (*m-n*)th subdiagonal contain the *m*-by-*n* upper trapezoidal matrix *R*;
 the remaining elements, with the array *taua*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors; the elements on and above the diagonal of the array *b* contain the $\min(p, n)$ -by-*n* upper trapezoidal matrix *T* (*T* is upper triangular if $p \geq n$); the elements below the diagonal, with the array *taub*, represent the orthogonal/unitary matrix *Z* as a product of elementary reflectors.

taua, taub REAL for sggrqf
 DOUBLE PRECISION for dggrqf
 COMPLEX for cggrqf
 DOUBLE COMPLEX for zggrqf.
 Arrays, DIMENSION at least $\max(1, \min(m, n))$ for *taua* and at least $\max(1, \min(p, n))$ for *taub*.
 The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*.
 The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggrqf` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>A</i> of size (<i>p</i> , <i>n</i>).
<i>taua</i>	Holds the vector of length min(<i>m</i> , <i>n</i>).
<i>taub</i>	Holds the vector of length min(<i>p</i> , <i>n</i>).

Application Notes

For better performance, try using

$$lwork \geq \max(n, m, p) * \max(nb1, nb2, nb3),$$

where *nb1* is the optimal blocksize for the *RQ* factorization of an *m*-by-*n* matrix, *nb2* is the optimal blocksize for the *QR* factorization of an *p*-by-*n* matrix, and *nb3* is the optimal blocksize for a call of `?ormrq/?unmrq`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork*= -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork*= -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Singular Value Decomposition

This section describes LAPACK routines for computing the *singular value decomposition* (SVD) of a general m -by- n matrix A :

$$A = U\Sigma V^H.$$

In this decomposition, U and V are unitary (for complex A) or orthogonal (for real A); Σ is an m -by- n diagonal matrix with real diagonal elements σ_i :

$$\sigma_1 < \sigma_2 < \dots < \sigma_{\min(m, n)} < 0.$$

The diagonal elements σ_i are *singular values* of A . The first $\min(m, n)$ columns of the matrices U and V are, respectively, *left* and *right singular vectors* of A . The singular values and singular vectors satisfy

$$AV_i = \sigma_i U_i \text{ and } A^H U_i = \sigma_i V_i$$

where U_i and V_i are the i -th columns of U and V , respectively.

To find the SVD of a general matrix A , call the LAPACK routine `?gebrd` or `?gbbbrd` for reducing A to a bidiagonal matrix B by a unitary (orthogonal) transformation: $A = QB P^H$. Then call `?bdsqr`, which forms the SVD of a bidiagonal matrix: $B = U_1 \Sigma V_1^H$.

Thus, the sought-for SVD of A is given by $A = U\Sigma V^H = (QU_1)\Sigma(V_1^H P^H)$.

Table 4-2 lists LAPACK routines (Fortran 77 interface) that perform singular value decomposition of matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-2 Computational Routines for Singular Value Decomposition (SVD)

Operation	Real matrices	Complex matrices

Figure 4-1 Decision Tree: Singular Value Decomposition

Figure 4-1 “Decision Tree: Singular Value Decomposition” presents a decision tree that helps you choose the right sequence of routines for SVD, depending on whether you need singular values only or singular vectors as well, whether A is real or complex, and so on.

You can use the SVD to find a minimum-norm solution to a (possibly) rank-deficient least squares problem of minimizing $\|Ax - b\|^2$. The effective rank k of the matrix A can be determined as the number of singular values which exceed a suitable threshold. The minimum-norm solution is

$$x = V_k (\Sigma_k)^{-1} c$$

where Σ_k is the leading k -by- k submatrix of Σ , the matrix V_k consists of the first k columns of $V = PV_1$, and the vector c consists of the first k elements of $U^H b = U_1^H Q^H b$.

?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

FORTRAN 77:

```
call sgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call dgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call cgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call zgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
```

Fortran 95:

```
call gebrd(a [, d] [,e] [,tauq] [,taup] [,info])
```

Description

The routine reduces a general m -by- n matrix A to a bidiagonal matrix B by an orthogonal (unitary) transformation.

$$A = QB P^H = Q \begin{pmatrix} B_1 \\ 0 \end{pmatrix} P^H = Q_1 B_1 P^H ,$$

If $m \geq n$, the reduction is given by

where B_1 is an n -by- n upper diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; Q_1 consists of the first n columns of Q .

If $m < n$, the reduction is given by

$$A = Q^* B^* P^H = Q^* (B_1 0) P^H = Q_1^* B_1 P_1^H ,$$

where B_1 is an m -by- m lower diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; P_1 consists of the first m rows of P .

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. Routines are provided to work with the matrices Q and P in this representation:

If the matrix A is real,

- to compute Q and P explicitly, call [?orgbr](#).

- to multiply a general matrix by Q or P , call `?ormbr`.

If the matrix A is complex,

- to compute Q and P explicitly, call `?ungbr`.
- to multiply a general matrix by Q or P , call `?unmbr`.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, *work* REAL for `sgebrd`
 DOUBLE PRECISION for `dgebrd`
 COMPLEX for `cgebrd`
 DOUBLE COMPLEX for `zgebrd`.

Arrays:
a(*lda*,*) contains the matrix A .
 The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$.

lwork INTEGER.
 The dimension of *work*; at least $\max(1, m, n)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a If $m \geq n$, the diagonal and first super-diagonal of *a* are overwritten by the upper bidiagonal matrix B . Elements below the diagonal are overwritten by details of Q , and the remaining elements are overwritten by details of P .

	If $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B. Elements above the diagonal are overwritten by details of P, and the remaining elements are overwritten by details of Q.
d	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the diagonal elements of B.
e	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B.
τ_{uq}, τ_{up}	REAL for sgebrd DOUBLE PRECISION for dgebrd COMPLEX for cgebrd DOUBLE COMPLEX for zgebrd. Arrays, DIMENSION at least $\max(1, \min(m, n))$. Contain further details of the matrices Q and P.
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebrd` interface are the following:

a	Holds the matrix A of size (m, n) .
d	Holds the vector of length $\min(m, n)$.
e	Holds the vector of length $\min(m, n) - 1$.
τ_{uq}	Holds the vector of length $\min(m, n)$.
τ_{up}	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using $lwork = (m + n) * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrices *Q*, *B*, and *P* satisfy $QB P^H = A + E$, where $\|E\|_2 = c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of *n*, and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is

$$(4/3) * n^2 * (3 * m - n) \text{ for } m \geq n,$$

$$(4/3) * m^2 * (3 * n - m) \text{ for } m < n.$$

The number of operations for complex flavors is four times greater.

If *n* is much less than *m*, it can be more efficient to first form the *QR* factorization of *A* by calling [?geqrf](#) and then reduce the factor *R* to bidiagonal form. This requires approximately $2 * n^2 * (m + n)$ floating-point operations.

If *m* is much less than *n*, it can be more efficient to first form the *LQ* factorization of *A* by calling [?gelqf](#) and then reduce the factor *L* to bidiagonal form. This requires approximately $2 * m^2 * (m + n)$ floating-point operations.

?gbbbrd

Reduces a general band matrix to bidiagonal form.

Syntax

FORTRAN 77:

```
call sgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, info)

call dgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, info)

call cgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, rwork, info)

call zgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, rwork, info)
```

Fortran 95:

```
call gbbbrd(a [, c] [,d] [,e] [,q] [,pt] [,kl] [,m] [,info])
```

Description

This routine reduces an m -by- n band matrix A to upper bidiagonal matrix B : $A = Q * B * P^H$. Here the matrices Q and P are orthogonal (for real A) or unitary (for complex A). They are determined as products of Givens rotation matrices, and may be formed explicitly by the routine if required. The routine can also update a matrix C as follows: $C = Q^H * C$.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'N' or 'Q' or 'P' or 'B'. If <i>vect</i> = 'N', neither Q nor P^H is generated. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^H . If <i>vect</i> = 'B', the routine generates both Q and P^H .
<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>ncc</i>	INTEGER. The number of columns in C ($ncc \geq 0$).

<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab, c, work</i>	REAL for <i>sgbbrd</i> DOUBLE PRECISION for <i>dgbbrd</i> COMPLEX for <i>cgbbrd</i> DOUBLE COMPLEX for <i>zgbbrd</i> . Arrays: <i>ab(ldab,*)</i> contains the matrix <i>A</i> in band storage (see Matrix Storage Schemes). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>c(ldc,*)</i> contains an <i>m</i> -by- <i>ncc</i> matrix <i>C</i> . If <i>ncc</i> = 0, the array <i>c</i> is not referenced. The second dimension of <i>c</i> must be at least $\max(1, ncc)$. <i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $2 \cdot \max(m, n)$ for real flavors, or $\max(m, n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ($ldab \geq kl + ku + 1$).
<i>ldq</i>	INTEGER. The first dimension of the output array <i>q</i> . $ldq \geq \max(1, m)$ if <i>vect</i> = 'Q' or 'B', $ldq \geq 1$ otherwise.
<i>ldpt</i>	INTEGER. The first dimension of the output array <i>pt</i> . $ldpt \geq \max(1, n)$ if <i>vect</i> = 'P' or 'B', $ldpt \geq 1$ otherwise.
<i>ldc</i>	INTEGER. The first dimension of the array <i>c</i> . $ldc \geq \max(1, m)$ if <i>ncc</i> > 0; $ldc \geq 1$ if <i>ncc</i> = 0.
<i>rwork</i>	REAL for <i>cgbbrd</i> DOUBLE PRECISION for <i>zgbbrd</i> . A workspace array, DIMENSION at least $\max(m, n)$.

Output Parameters

<i>ab</i>	Overwritten by values generated during the reduction.
<i>d</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

	Array, <code>DIMENSION</code> at least $\max(1, \min(m, n))$. Contains the diagonal elements of the matrix B .
e	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, <code>DIMENSION</code> at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B .
q, pt	REAL for sgebrd DOUBLE PRECISION for dgebrd COMPLEX for cgebrd DOUBLE COMPLEX for zgebrd. Arrays: $q(ldq, *)$ contains the output m -by- m matrix Q . The second dimension of q must be at least $\max(1, m)$. $p(ldpt, *)$ contains the output n -by- n matrix P^T . The second dimension of pt must be at least $\max(1, n)$.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbbrd` interface are the following:

a	Stands for argument ab in Fortran 77 interface . Holds the array A of size $(kl+ku+1, n)$.
c	Holds the matrix C of size (m, ncc) .
d	Holds the vector of length $\min(m, n)$.
e	Holds the vector of length $\min(m, n)-1$.
q	Holds the matrix Q of size (m, m) .
pt	Holds the matrix PT of size (n, n) .
m	If omitted, assumed $m = n$.
kl	If omitted, assumed $kl = ku$.
ku	Restored as $ku = lda - kl - 1$.

`vect`

Restored based on the presence of arguments q and pt as follows:

`vect` = 'B', if both q and pt are present,

`vect` = 'Q', if q is present and pt omitted, `vect` = 'P',

if q is omitted and pt present, `vect` = 'N', if both q and pt are omitted.

Application Notes

The computed matrices Q , B , and P satisfy $Q^*B^*P^H = A + E$, where $\|E\|_2 = c(n)\varepsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ε is the machine precision.

If $m = n$, the total number of floating-point operations for real flavors is approximately the sum of:

$6n^2(kl + ku)$ if `vect` = 'N' and $ncc = 0$,

$3n^2ncc(kl + ku - 1)/(kl + ku)$ if C is updated, and

$3n^3(kl + ku - 1)/(kl + ku)$ if either Q or P^H is generated (double this if both).

To estimate the number of operations for complex flavors, use the same formulas with the coefficients 20 and 10 (instead of 6 and 3).

?orgbr

Generates the real orthogonal matrix Q or P^T determined by ?gebrd.

Syntax

FORTRAN 77:

```
call sorgbr(vect, m, n, k, a, lda, tau, work, lwork, info)
```

```
call dorgbr(vect, m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgbr(a, tau [,vect] [,info])
```

Description

The routine generates the whole or part of the orthogonal matrices Q and P_T formed by the routines [sgebrd](#)/[dgebrd](#). Use this routine after a call to [sgebrd](#)/[dgebrd](#). All valid combinations of arguments are described in *Input parameters*. In most cases you need the following:

To compute the whole m -by- m matrix Q :

```
call ?orgbr('Q', m, m, n, a ... )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$:

```
call ?orgbr('Q', m, n, n, a ... )
```

To compute the whole n -by- n matrix P^T :

```
call ?orgbr('P', n, n, m, a ... )
```

(note that the array a must have at least n rows).

To form the m leading rows of P^T if $m < n$:

```
call ?orgbr('P', m, n, m, a ... )
```

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'Q' or 'P'. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^T .
<i>m</i>	INTEGER. The number of required rows of Q or P^T .
<i>n</i>	INTEGER. The number of required columns of Q or P^T .
<i>k</i>	INTEGER. One of the dimensions of A in ?gebrd: If <i>vect</i> = 'Q', the number of columns in A ; If <i>vect</i> = 'P', the number of rows in A . Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$. For <i>vect</i> = 'Q': $k \leq n \leq m$ if $m > k$, or $m = n$ if $m \leq k$. For <i>vect</i> = 'P': $k \leq m \leq n$ if $n > k$, or $m = n$ if $n \leq k$.
<i>a, work</i>	REAL for sorgbr DOUBLE PRECISION for dorgbr. Arrays: <i>a(lda,*)</i> is the array a as returned by ?gebrd. The second dimension of a must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a ; at least $\max(1, m)$.
<i>tau</i>	REAL for sorgbr DOUBLE PRECISION for dorgbr.

For $\text{vect} = 'Q'$, the array tauq as returned by `?gebrd`.
 For $\text{vect} = 'P'$, the array taup as returned by `?gebrd`.
 The dimension of tau must be at least $\max(1, \min(m, k))$
 for $\text{vect} = 'Q'$, or $\max(1, \min(m, k))$ for $\text{vect} = 'P'$.
 lwork INTEGER. The size of the work array.
 If $\text{lwork} = -1$, then a workspace query is assumed; the
 routine only calculates the optimal size of the work array,
 returns this value as the first entry of the work array, and
 no error message related to lwork is issued by `xerbla`.
 See *Application Notes* for the suggested value of lwork .

Output Parameters

a Overwritten by the orthogonal matrix Q or P^T (or the leading
 rows or columns thereof) as specified by vect , m , and n .
 $\text{work}(1)$ If $\text{info} = 0$, on exit $\text{work}(1)$ contains the minimum value
 of lwork required for optimum performance. Use this lwork
 for subsequent runs.
 info INTEGER.
 If $\text{info} = 0$, the execution is successful.
 If $\text{info} = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgbr` interface are the following:

a Holds the matrix A of size (m, n) .
 tau Holds the vector of length $\min(m, k)$ where
 $k = m$, if $\text{vect} = 'P'$,
 $k = n$, if $\text{vect} = 'Q'$.
 vect Must be $'Q'$ or $'P'$. The default value is $'Q'$.

Application Notes

For better performance, try using $lwork = \min(m, n) * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The approximate numbers of floating-point operations for the cases listed in *Description* are as follows:

To form the whole of *Q*:

$$(4/3) * n * (3m^2 - 3m * n + n^2) \text{ if } m > n;$$

$$(4/3) * m^3 \text{ if } m \leq n.$$

To form the *n* leading columns of *Q* when $m > n$:

$$(2/3) * n^2 * (3m - n^2) \text{ if } m > n.$$

To form the whole of P^T :

$$(4/3) * n^3 \text{ if } m \geq n;$$

$$(4/3) * m * (3n^2 - 3m * n + m^2) \text{ if } m < n.$$

To form the *m* leading columns of P^T when $m < n$:

$$(2/3) * n^2 * (3m - n^2) \text{ if } m > n.$$

The complex counterpart of this routine is [?ungbr](#).

[?ormbr](#)

Multiplies an arbitrary real matrix by the real orthogonal matrix Q or P^T determined by [?gebrd](#).

Syntax

FORTRAN 77:

```
call sormbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork,
info)

call dormbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork,
info)
```

Fortran 95:

```
call ormbr(a, tau, c [,vect] [,side] [,trans] [,info])
```

Description

Given an arbitrary real matrix C , this routine forms one of the matrix products Q^*C , $Q^T C$, C^*Q , C^*Q^T , P^*C , $P^T C$, C^*P , C^*P^T , where Q and P are orthogonal matrices computed by a call to [sgebrd](#)/[dgebrd](#). The routine overwrites the product on C .

Input Parameters

In the descriptions below, r denotes the order of Q or P^T :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

$vect$	CHARACTER*1. Must be 'Q' or 'P'. If $vect = 'Q'$, then Q or Q^T is applied to C . If $vect = 'P'$, then P or P_T is applied to C .
$side$	CHARACTER*1. Must be 'L' or 'R'. If $side = 'L'$, multipliers are applied to C from the left. If $side = 'R'$, they are applied to C from the right.
$trans$	CHARACTER*1. Must be 'N' or 'T'. If $trans = 'N'$, then Q or P is applied to C . If $trans = 'T'$, then Q^T or P^T is applied to C .
m	INTEGER. The number of rows in C .

<i>n</i>	INTEGER. The number of columns in <i>C</i> .
<i>k</i>	INTEGER. One of the dimensions of <i>A</i> in ?gebrd: If <i>vect</i> = 'Q', the number of columns in <i>A</i> ; If <i>vect</i> = 'P', the number of rows in <i>A</i> . Constraints: $m \geq 0, n \geq 0, k \geq 0$.
<i>a, c, work</i>	REAL for sormbr DOUBLE PRECISION for dormbr. Arrays: <i>a(lda,*)</i> is the array <i>a</i> as returned by ?gebrd. Its second dimension must be at least $\max(1, \min(r, k))$ for <i>vect</i> = 'Q', or $\max(1, r)$ for <i>vect</i> = 'P'. <i>c ldc,*)</i> holds the matrix <i>C</i> . Its second dimension must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> . Constraints: $lda \geq \max(1, r)$ if <i>vect</i> = 'Q'; $lda \geq \max(1, \min(r, k))$ if <i>vect</i> = 'P'.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, m)$.
<i>tau</i>	REAL for sormbr DOUBLE PRECISION for dormbr. Array, DIMENSION at least $\max(1, \min(r, k))$. For <i>vect</i> = 'Q', the array <i>tauq</i> as returned by ?gebrd. For <i>vect</i> = 'P', the array <i>taup</i> as returned by ?gebrd.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>c</i>	Overwritten by the product $Q^*C, Q^{T*}C, C^*Q, C^*Q^T, P^*C, P^{T*}C, C^*P$, or C^*P^T , as specified by <i>vect</i> , <i>side</i> , and <i>trans</i> .

<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormbr` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size $(r, \min(nq, k))$ where $r = nq$, if <code>vect = 'Q'</code> , $r = \min(nq, k)$, if <code>vect = 'P'</code> , $nq = m$, if <code>side = 'L'</code> , $nq = n$, if <code>side = 'R'</code> , $k = m$, if <code>vect = 'P'</code> , $k = n$, if <code>vect = 'Q'</code> .
<code>tau</code>	Holds the vector of length $\min(nq, k)$.
<code>c</code>	Holds the matrix <i>C</i> of size (m, n) .
<code>vect</code>	Must be 'Q' or 'P'. The default value is 'Q'.
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using

`lwork = n*blocksize` for `side = 'L'`, or

`lwork = m*blocksize` for `side = 'R'`,

where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$2*n*k(2*m - k)$ if *side* = 'L' and $m \geq k$;

$2*m*k(2*n - k)$ if *side* = 'R' and $n \geq k$;

$2*m^2*n$ if *side* = 'L' and $m < k$;

$2*n^2*m$ if *side* = 'R' and $n < k$.

The complex counterpart of this routine is [?unmbr](#).

?ungbr

Generates the complex unitary matrix Q or P^H determined by ?gebrd.

Syntax

FORTRAN 77:

```
call cungrb(vect, m, n, k, a, lda, tau, work, lwork, info)
call zungrb(vect, m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungbr(a, tau [,vect] [,info])
```

Description

The routine generates the whole or part of the unitary matrices Q and P_H formed by the routines [cgebrd/zgebrd](#). Use this routine after a call to [cgebrd/zgebrd](#). All valid combinations of arguments are described in *Input Parameters*; in most cases you need the following:

To compute the whole m -by- m matrix Q , use:

```
call ?ungbr('Q', m, m, n, a ... )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$, use:

```
call ?ungbr('Q', m, n, n, a ... )
```

To compute the whole n -by- n matrix P^H , use:

```
call ?ungbr('P', n, n, m, a ... )
```

(note that the array a must have at least n rows).

To form the m leading rows of P_H if $m < n$, use:

```
call ?ungbr('P', m, n, m, a ... )
```

Input Parameters

$vect$	CHARACTER*1. Must be 'Q' or 'P'. If $vect = 'Q'$, the routine generates the matrix Q . If $vect = 'P'$, the routine generates the matrix P^H .
m	INTEGER. The number of required rows of Q or P^H .
n	INTEGER. The number of required columns of Q or P^H .
k	INTEGER. One of the dimensions of A in ?gebrd : If $vect = 'Q'$, the number of columns in A ; If $vect = 'P'$, the number of rows in A . Constraints: $m \geq 0, n \geq 0, k \geq 0$. For $vect = 'Q'$: $k \leq n \leq m$ if $m > k$, or $m = n$ if $m \leq k$. For $vect = 'P'$: $k \leq m \leq n$ if $n > k$, or $m = n$ if $n \leq k$.
$a, work$	COMPLEX for cungbr DOUBLE COMPLEX for zungbr . Arrays: $a(lda,*)$ is the array a as returned by ?gebrd . The second dimension of a must be at least $\max(1, n)$.

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$.

tau COMPLEX for *cungbr*
DOUBLE COMPLEX for *zungbr*.
For *vect* = 'Q', the array *tauq* as returned by ?gebrd.
For *vect* = 'P', the array *taup* as returned by ?gebrd.
The dimension of *tau* must be at least $\max(1, \min(m, k))$ for *vect* = 'Q', or $\max(1, \min(m, k))$ for *vect* = 'P'.

lwork INTEGER. The size of the *work* array.
Constraint: $lwork < \max(1, \min(m, n))$.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by the orthogonal matrix *Q* or P^T (or the leading rows or columns thereof) as specified by *vect*, *m*, and *n*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ungbr* interface are the following:

a Holds the matrix *A* of size (m, n) .

tau Holds the vector of length $\min(m, k)$ where $k = m$, if *vect* = 'P',

$k = n$, if $vect = 'Q'$.
 $vect$ Must be 'Q' or 'P'. The default value is 'Q'.

Application Notes

For better performance, try using $lwork = \min(m, n) * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$.

The approximate numbers of possible floating-point operations are listed below:

To compute the whole matrix Q :

$$(16/3)n(3m^2 - 3m*n + n^2) \text{ if } m > n;$$

$$(16/3)m^3 \text{ if } m \leq n.$$

To form the n leading columns of Q when $m > n$:

$$(8/3)n^2(3m - n^2).$$

To compute the whole matrix P^H :

$$(16/3)n^3 \text{ if } m \geq n;$$

$$(16/3)m(3n^2 - 3m*n + m^2) \text{ if } m < n.$$

To form the m leading columns of P^H when $m < n$:

$(8/3)n^2(3m - n^2)$ if $m > n$.

The real counterpart of this routine is [?orgbr](#).

?unmbr

Multiplies an arbitrary complex matrix by the unitary matrix Q or P determined by ?gebrd.

Syntax

FORTRAN 77:

```
call cunmbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork,
info)

call zunmbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork,
info)
```

Fortran 95:

```
call unmbr(a, tau, c [,vect] [,side] [,trans] [,info])
```

Description

Given an arbitrary complex matrix C , this routine forms one of the matrix products Q^*C , Q^H*C , $C*Q$, $C*Q^H$, P^*C , P^H*C , $C*P$, or $C*P^H$, where Q and P are unitary matrices computed by a call to [cgebrd](#)/[zgebrd](#). The routine overwrites the product on C .

Input Parameters

In the descriptions below, r denotes the order of Q or P^H :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

<i>vect</i>	CHARACTER*1. Must be 'Q' or 'P'. If <i>vect</i> = 'Q', then Q or Q^H is applied to C . If <i>vect</i> = 'P', then P or P^H is applied to C .
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', multipliers are applied to C from the left. If <i>side</i> = 'R', they are applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'C'. If <i>trans</i> = 'N', then Q or P is applied to C . If <i>trans</i> = 'C', then Q^H or P^H is applied to C .

m INTEGER. The number of rows in C .
 n INTEGER. The number of columns in C .
 k INTEGER. One of the dimensions of A in ?gebrd:
 If $vect = 'Q'$, the number of columns in A ;
 If $vect = 'P'$, the number of rows in A .
 Constraints: $m \geq 0, n \geq 0, k \geq 0$.
 $a, c, work$ COMPLEX for cunmbr
 DOUBLE COMPLEX for zunmbr.
 Arrays:
 $a(lda,*)$ is the array a as returned by ?gebrd.
 Its second dimension must be at least $\max(1, \min(r, k))$ for
 $vect = 'Q'$, or $\max(1, r)$ for $vect = 'P'$.
 $c(ldc,*)$ holds the matrix C .
 Its second dimension must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1,$
 $lwork)$.
 lda INTEGER. The first dimension of a . Constraints:
 $lda \geq \max(1, r)$ if $vect = 'Q'$;
 $lda \geq \max(1, \min(r, k))$ if $vect = 'P'$.
 ldc INTEGER. The first dimension of c ; $ldc \geq \max(1, m)$.
 tau COMPLEX for cunmbr
 DOUBLE COMPLEX for zunmbr.
 Array, DIMENSION at least $\max(1, \min(r, k))$.
 For $vect = 'Q'$, the array $tauq$ as returned by ?gebrd.
 For $vect = 'P'$, the array $taup$ as returned by ?gebrd.
 $lwork$ INTEGER. The size of the $work$ array.
 $lwork \geq \max(1, n)$ if $side = 'L'$;
 $lwork \geq \max(1, m)$ if $side = 'R'$.
 $lwork \geq 1$ if $n=0$ or $m=0$.
 For optimum performance $lwork \geq \max(1, n*nb)$ if $side$
 $= 'L'$, and $lwork \geq \max(1, m*nb)$ if $side = 'R'$, where
 nb is the optimal blocksize. ($nb = 0$ if $m = 0$ or $n =$
 0 .)

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c	Overwritten by the product $Q^H C$, $Q^H C$, $C^H Q$, $C^H Q$, $P^H C$, $P^H C$, $C^H P$, or $C^H P$, as specified by $vect$, $side$, and $trans$.
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmbr` interface are the following:

a	Holds the matrix A of size $(r, \min(nq, k))$ where $r = nq$, if $vect = 'Q'$, $r = \min(nq, k)$, if $vect = 'P'$, $nq = m$, if $side = 'L'$, $nq = n$, if $side = 'R'$, $k = m$, if $vect = 'P'$, $k = n$, if $vect = 'Q'$.
τ	Holds the vector of length $\min(nq, k)$.
c	Holds the matrix C of size (m, n) .
$vect$	Must be 'Q' or 'P'. The default value is 'Q'.
$side$	Must be 'L' or 'R'. The default value is 'L'.
$trans$	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, use

$lwork = n * blocksize$ for $side = 'L'$, or

$lwork = m * blocksize$ for $side = 'R'$,

where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$8 * n * k (2 * m - k)$ if $side = 'L'$ and $m \geq k$;

$8 * m * k (2 * n - k)$ if $side = 'R'$ and $n \geq k$;

$8 * m^2 * n$ if $side = 'L'$ and $m < k$;

$8 * n^2 * m$ if $side = 'R'$ and $n < k$.

The real counterpart of this routine is [?ormbr](#).

?bdsqr

Computes the singular value decomposition of a general matrix that has been reduced to bidiagonal form.

Syntax

FORTRAN 77:

```
call sbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)

call dbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)

call cbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)

call zbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)
```

Fortran 95:

```
call rbdsqr(d, e [,vt] [,u] [,c] [,uplo] [,info])
call bdsqr(d, e [,vt] [,u] [,c] [,uplo] [,info])
```

Description

This routine computes the singular values and, optionally, the right and/or left singular vectors from the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form $B = Q * S * P^H$ where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns $U * Q$ instead of Q , and, if right singular vectors are requested, this subroutine returns $P_H * VT$ instead of P_H , for given real/complex input matrices U and VT . When U and VT are the orthogonal/unitary matrices that reduce a general matrix A to bidiagonal form: $A = U * B * VT$, as computed by ?gebrd, then

$$A = (U * Q) * S * (P^H * VT)$$

is the SVD of A . Optionally, the subroutine may also compute $Q_H * C$ for a given real/complex input matrix C .

See also [?lasq1](#), [?lasq2](#), [?lasq3](#), [?lasq4](#), [?lasq5](#), [?lasq6](#) used by this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>B</i> is an upper bidiagonal matrix. If <i>uplo</i> = 'L', <i>B</i> is a lower bidiagonal matrix.
<i>n</i>	INTEGER. The order of the matrix <i>B</i> ($n \geq 0$).
<i>ncvt</i>	INTEGER. The number of columns of the matrix <i>VT</i>, that is, the number of right singular vectors ($ncvt \geq 0$). Set <i>ncvt</i> = 0 if no right singular vectors are required.
<i>nru</i>	INTEGER. The number of rows in <i>U</i>, that is, the number of left singular vectors ($nru \geq 0$). Set <i>nru</i> = 0 if no left singular vectors are required.
<i>ncc</i>	INTEGER. The number of columns in the matrix <i>C</i> used for computing the product $Q^H * C$ ($ncc \geq 0$). Set <i>ncc</i> = 0 if no matrix <i>C</i> is supplied.
<i>d</i> , <i>e</i> , <i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i>(*) contains the diagonal elements of <i>B</i>. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i>(*) contains the $(n-1)$ off-diagonal elements of <i>B</i>. The dimension of <i>e</i> must be at least $\max(1, n)$. <i>e</i>(<i>n</i>) is used for workspace. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 2*n)$ if $ncvt = nru = ncc = 0$; $\max(1, 4*(n-1))$ otherwise.
<i>vt</i> , <i>u</i> , <i>c</i>	REAL for sbdsqr DOUBLE PRECISION for dbdsqr COMPLEX for cbdsqr DOUBLE COMPLEX for zbdsqr. Arrays: <i>vt</i>(<i>ldvt</i>,*) contains an <i>n</i>-by-<i>ncvt</i> matrix <i>VT</i>. The second dimension of <i>vt</i> must be at least $\max(1, ncvt)$.

vt is not referenced if $ncvt = 0$.
 $u(ldu, *)$ contains an nru by n unit matrix U .
 The second dimension of u must be at least $\max(1, n)$.
 u is not referenced if $nru = 0$.
 $c ldc, *)$ contains the matrix C for computing the product $Q^H * C$.
 The second dimension of c must be at least $\max(1, ncc)$.
 The array is not referenced if $ncc = 0$.

$ldvt$ INTEGER. The first dimension of vt . Constraints:
 $ldvt \geq \max(1, n)$ if $ncvt > 0$;
 $ldvt \geq 1$ if $ncvt = 0$.

ldu INTEGER. The first dimension of u . Constraint:
 $ldu \geq \max(1, nru)$.

ldc INTEGER. The first dimension of c . Constraints:
 $ldc \geq \max(1, n)$ if $ncc > 0$; $ldc \geq 1$ otherwise.

Output Parameters

d On exit, if $info = 0$, overwritten by the singular values in decreasing order (see $info$).

e On exit, if $info = 0$, e is destroyed. See also $info$ below.

c Overwritten by the product $Q^H * C$.

vt On exit, this array is overwritten by $P^H * VT$.

u On exit, this array is overwritten by $U * Q$.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, the algorithm failed to converge; i specifies how many off-diagonals did not converge.
 In this case, d and e contain on exit the diagonal and off-diagonal elements, respectively, of a bidiagonal matrix orthogonally equivalent to B .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `bdsqr` interface are the following:

<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length (n) .
<code>vt</code>	Holds the matrix VT of size (n, ncv) .
<code>u</code>	Holds the matrix U of size (nru, n) .
<code>c</code>	Holds the matrix C of size (n, ncc) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>ncv</code>	If argument <code>vt</code> is present, then <code>ncv</code> is equal to the number of columns in matrix VT ; otherwise, <code>ncv</code> is set to zero.
<code>nru</code>	If argument <code>u</code> is present, then <code>nru</code> is equal to the number of rows in matrix U ; otherwise, <code>nru</code> is set to zero.
<code>ncc</code>	If argument <code>c</code> is present, then <code>ncc</code> is equal to the number of columns in matrix C ; otherwise, <code>ncc</code> is set to zero.

Note that two variants of Fortran 95 interface for `bdsqr` routine are needed because of an ambiguous choice between real and complex cases appear when `vt`, `u`, and `c` are omitted. Thus, the name `rbdsqr` is used in real cases (single or double precision), and the name `bdsqr` is used in complex cases (single or double precision).

Application Notes

Each singular value and singular vector is computed to high relative accuracy. However, the reduction to bidiagonal form (prior to calling the routine) may decrease the relative accuracy in the small singular values of the original matrix if its singular values vary widely in magnitude.

If s_i is an exact singular value of B , and s_i is the corresponding computed value, then

$$|s_i - \sigma_i| \leq p(m, n) * \epsilon * \sigma_i$$

where $p(m, n)$ is a modestly increasing function of m and n , and ϵ is the machine precision.

If only singular values are computed, they are computed more accurately than when some singular vectors are also computed (that is, the function $p(m, n)$ is smaller).

If u_i is the corresponding exact left singular vector of B , and w_i is the corresponding computed left singular vector, then the angle $\theta(u_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq p(m, n) * \epsilon / \min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|).$$

Here $\min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|)$ is the *relative gap* between σ_i and the other singular values. A similar error bound holds for the right singular vectors.

The total number of real floating-point operations is roughly proportional to n^2 if only the singular values are computed. About $6n^2 * nru$ additional operations ($12n^2 * nru$ for complex flavors) are required to compute the left singular vectors and about $6n^2 * ncvt$ operations ($12n^2 * ncvt$ for complex flavors) to compute the right singular vectors.

?bdsdc

Computes the singular value decomposition of a real bidiagonal matrix using a divide and conquer method.

Syntax

FORTRAN 77:

```
call sbdsdc(uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)
call dbdsdc(uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)
```

Fortran 95:

```
call bdsdc(d, e [,u] [,vt] [,q] [,iq] [,uplo] [,info])
```

Description

This routine computes the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B : $B = U * \Sigma * V^T$, using a divide and conquer method, where Σ is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and V are orthogonal matrices of left and right singular vectors, respectively. `?bdsdc` can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This routine uses `?lasd0`, `?lasd1`, `?lasd2`, `?lasd3`, `?lasd4`, `?lasd5`, `?lasd6`, `?lasd7`, `?lasd8`, `?lasd9`, `?lasda`, `?lasdq`, `?lasdt`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>B</i> is an upper bidiagonal matrix. If <i>uplo</i> = 'L', <i>B</i> is a lower bidiagonal matrix.
<i>compq</i>	CHARACTER*1. Must be 'N', 'P', or 'I'. If <i>compq</i> = 'N', compute singular values only. If <i>compq</i> = 'P', compute singular values and compute singular vectors in compact form. If <i>compq</i> = 'I', compute singular values and singular vectors.
<i>n</i>	INTEGER. The order of the matrix <i>B</i> ($n \geq 0$).
<i>d</i> , <i>e</i> , <i>work</i>	REAL for sbdsdc DOUBLE PRECISION for dbdsdc. Arrays: <i>d</i>(*) contains the <i>n</i> diagonal elements of the bidiagonal matrix <i>B</i>. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i>(*) contains the off-diagonal elements of the bidiagonal matrix <i>B</i>. The dimension of <i>e</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least: $\max(1, 4*n)$, if <i>compq</i> = 'N'; $\max(1, 6*n)$, if <i>compq</i> = 'P'; $\max(1, 3*n^2+4*n)$, if <i>compq</i> = 'I'.
<i>ldu</i>	INTEGER. The first dimension of the output array <i>u</i>; $ldu \geq 1$. If singular vectors are desired, then $ldu \geq \max(1, n)$.
<i>ldvt</i>	INTEGER. The first dimension of the output array <i>vt</i>; $ldvt \geq 1$. If singular vectors are desired, then $ldvt \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, dimension at least $\max(1, 8*n)$.

Output Parameters

<i>d</i>	If <i>info</i> = 0, overwritten by the singular values of <i>B</i> .
<i>e</i>	On exit, <i>e</i> is overwritten.
<i>u</i> , <i>vt</i> , <i>q</i>	REAL for sbdsdc DOUBLE PRECISION for dbdsdc. Arrays: <i>u</i>(<i>ldu</i>,*), <i>vt</i>(<i>ldvt</i>,*), <i>q</i>(*). If <i>compq</i> = 'I', then on exit <i>u</i> contains the left singular vectors of the bidiagonal matrix <i>B</i>, unless <i>info</i> ≠ 0 (see <i>info</i>). For other values of <i>compq</i>, <i>u</i> is not referenced. The second dimension of <i>u</i> must be at least max(1,<i>n</i>). If <i>compq</i> = 'I', then on exit <i>vt</i> contains the right singular vectors of the bidiagonal matrix <i>B</i>, unless <i>info</i> ≠ 0 (see <i>info</i>). For other values of <i>compq</i>, <i>vt</i> is not referenced. The second dimension of <i>vt</i> must be at least max(1,<i>n</i>). If <i>compq</i> = 'P', then on exit, if <i>info</i> = 0, <i>q</i> and <i>iq</i> contain the left and right singular vectors in a compact form. Specifically, <i>q</i> contains all the REAL (for sbdsdc) or DOUBLE PRECISION (for dbdsdc) data for singular vectors. For other values of <i>compq</i>, <i>q</i> is not referenced. See <i>Application notes</i> for details.
<i>iq</i>	INTEGER. Array: <i>iq</i>(*). If <i>compq</i> = 'P', then on exit, if <i>info</i> = 0, <i>q</i> and <i>iq</i> contain the left and right singular vectors in a compact form. Specifically, <i>iq</i> contains all the INTEGER data for singular vectors. For other values of <i>compq</i>, <i>iq</i> is not referenced. See <i>Application notes</i> for details.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = <i>i</i>, the algorithm failed to compute a singular value. The update process of divide and conquer failed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `bdsdc` interface are the following:

<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length (n) .
<code>u</code>	Holds the matrix U of size (n, n) .
<code>vt</code>	Holds the matrix VT of size (n, n) .
<code>q</code>	Holds the vector of length (ldq) , where $ldq \geq n * (11 + 2 * smlsiz + 8 * \text{int}(\log_2(n / (smlsiz + 1))))$ and <code>smlsiz</code> is returned by <code>ilaenv</code> and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25).
<code>compq</code>	Restored based on the presence of arguments <code>u</code> , <code>vt</code> , <code>q</code> , and <code>iq</code> as follows: <code>compq</code> = 'N', if none of <code>u</code> , <code>vt</code> , <code>q</code> , and <code>iq</code> are present, <code>compq</code> = 'I', if both <code>u</code> and <code>vt</code> are present. Arguments <code>u</code> and <code>vt</code> must either be both present or both omitted, <code>compq</code> = 'P', if both <code>q</code> and <code>iq</code> are present. Arguments <code>q</code> and <code>iq</code> must either be both present or both omitted. Note that there will be an error condition if all of <code>u</code> , <code>vt</code> , <code>q</code> , and <code>iq</code> arguments are present simultaneously.

Symmetric Eigenvalue Problems

Symmetric eigenvalue problems are posed as follows: given an n -by- n real symmetric or complex Hermitian matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (or, equivalently, } z^H A = \lambda z^H \text{)}.$$

In such eigenvalue problems, all n eigenvalues are real not only for real symmetric but also for complex Hermitian matrices A , and there exists an orthonormal system of n eigenvectors. If A is a symmetric or Hermitian positive-definite matrix, all eigenvalues are positive.

To solve a symmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to tridiagonal form and then solve the eigenvalue problem with the tridiagonal matrix obtained. LAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines (for Fortran 77 interface) are listed in [Table 4-3](#). Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

There are different routines for symmetric eigenvalue problems, depending on whether you need all eigenvectors or only some of them or eigenvalues only, whether the matrix A is positive-definite or not, and so on.

These routines are based on three primary algorithms for computing eigenvalues and eigenvectors of symmetric problems: the divide and conquer algorithm, the QR algorithm, and bisection followed by inverse iteration. The divide and conquer algorithm is generally more efficient and is recommended for computing all eigenvalues and eigenvectors. Furthermore, to solve an eigenvalue problem using the divide and conquer algorithm, you need to call only one routine. In general, more than one routine has to be called if the QR algorithm or bisection followed by inverse iteration is used.

Decision tree in [Figure 4-2](#) will help you choose the right routine or sequence of routines for eigenvalue problems with real symmetric matrices. A similar decision tree for complex Hermitian matrices is presented in [Figure 4-3](#).

?sytrd

Reduces a real symmetric matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call ssytrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
call dsytrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
```

Fortran 95:

```
call sytrd(a, tau [,uplo] [,info])
```

Description

This routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^* T Q^T$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

This routine calls [?latrd](#) to reduce a real symmetric matrix to tridiagonal form by an orthogonal similarity transformation.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for ssytrd DOUBLE PRECISION for dsytrd. <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$).

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>a</i>	Overwritten by the tridiagonal matrix <i>T</i> and details of the orthogonal matrix <i>Q</i> , as specified by <i>uplo</i> .
<i>d</i> , <i>e</i> , <i>tau</i>	REAL for ssytrd DOUBLE PRECISION for dsytrd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>tau</i> (*) stores further details of the orthogonal matrix <i>Q</i> in the first $n-1$ elements. <i>tau</i> (<i>n</i>) is used as workspace. The dimension of <i>tau</i> must be at least $\max(1, n)$.
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sytrd* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>tau</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length (n) .
<i>e</i>	Holds the vector of length $(n-1)$.

`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using `lwork = n*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

`?orgtr` to form the computed matrix Q explicitly
`?ormtr` to multiply a real matrix by Q .

The complex counterpart of this routine is `?hetrd`.

?syldb

Reduces a real symmetric matrix to tridiagonal form with Successive Bandwidth Reduction approach.

Syntax

FORTRAN 77:

```
call ssyldb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
call dsyldb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
```

Description

This routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^* T^* Q^T$ and optionally multiplies matrix Z by Q , or simply forms Q .

This routine reduces a full symmetric matrix to the banded symmetric form, and then to the tridiagonal symmetric form with a Successive Bandwidth Reduction approach after Prof. C.Bischof's works (see for instance, [Bischof92]). ?syldb is functionally close to ?sytrd routine but the tridiagonal form may differ from those obtained by ?sytrd. Unlike ?sytrd, the orthogonal matrix Q cannot be restored from the details of matrix A on exit.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only A is reduced to T . If <i>jobz</i> = 'V', then A is reduced to T and A contains Q on exit. If <i>jobz</i> = 'U', then A is reduced to T and Z contains Z^*Q on exit.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The bandwidth of the banded matrix B ($kd \geq 1$).
<i>a, z, work</i>	REAL for ssyldb.

DOUBLE PRECISION for dsyrdb.
 $a(lda,*)$ is an array containing either upper or lower triangular part of the matrix A , as specified by $uplo$.
The second dimension of a must be at least $\max(1, n)$.
 $z(ldz,*)$, the second dimension of z must be at least $\max(1, n)$.
If $jobz = 'U'$, then the matrix z is multiplied by Q .
If $jobz = 'N'$ or $'V'$, then z is not referenced.
 $work(lwork)$ is a workspace array.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.
ldz INTEGER. The first dimension of z ; at least $\max(1, n)$. Not referenced if $jobz = 'N'$.

lwork INTEGER. The size of the $work$ array ($lwork \geq (2kd+1)n+kd$).
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.
See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a If $jobz = 'V'$, then overwritten by Q matrix.
If $jobz = 'N'$ or $'U'$, then overwritten by the banded matrix B and details of the orthogonal matrix Q_B to reduce A to B as specified by $uplo$.

 z On exit,
if $jobz = 'U'$, then the matrix z is overwritten by z^*Q .
If $jobz = 'N'$ or $'V'$, then z is not referenced.

 d, e, tau DOUBLE PRECISION.
Arrays:
 $d(*)$ contains the diagonal elements of the matrix T .
The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of T .
The dimension of e must be at least $\max(1, n-1)$.
 $tau(*)$ stores further details of the orthogonal matrix Q .
The dimension of tau must be at least $\max(1, n-kd-1)$.

work(1) If *info*=0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Application Notes

For better performance, try using $lwork = n*(3*kd+3)$.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using *kd* equal to 40 if $n \leq 2000$ and 64 otherwise.

Try using ?syrdB instead of ?sytrd on large matrices obtaining only eigenvalues - when no eigenvectors are needed, especially in multi-threaded environment. ?syrdB becomes faster beginning approximately with $n = 1000$, and much faster at larger matrices with a better scalability than ?sytrd.

Avoid applying ?syrdB for computing eigenvectors due to the two-step reduction, that is, the number of operations needed to apply orthogonal transformations to *z* is doubled compared to the traditional one-step reduction. In that case it is better to apply ?sytrd and ?ormtr/?orgtr to obtain tridiagonal form along with the orthogonal transformation matrix *Q*.

?herdb

Reduces a complex Hermitian matrix to tridiagonal form with Successive Bandwidth Reduction approach.

Syntax

FORTRAN 77:

```
call cherdb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
call zherdb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
```

Description

This routine reduces a complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^* T Q^T$ and optionally multiplies matrix Z by Q , or simply forms Q .

This routine reduces a full Hermitian matrix to the banded Hermitian form, and then to the tridiagonal symmetric form with a Successive Bandwidth Reduction approach after Prof. C.Bischof's works (see for instance, [Bischof92]). ?herdb is functionally close to ?hetrd routine but the tridiagonal form may differ from those obtained by ?hetrd. Unlike ?hetrd, the orthogonal matrix Q cannot be restored from the details of matrix A on exit.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only A is reduced to T . If <i>jobz</i> = 'V', then A is reduced to T and A contains Q on exit. If <i>jobz</i> = 'U', then A is reduced to T and Z contains $Z^* Q$ on exit.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The bandwidth of the banded matrix B ($kd \geq 1$).
<i>a, z, work</i>	COMPLEX for cherdb.

DOUBLE COMPLEX for zherdb.
 $a(lda,*)$ is an array containing either upper or lower triangular part of the matrix A , as specified by $uplo$.
 The second dimension of a must be at least $\max(1, n)$.
 $z(ldz,*)$, the second dimension of z must be at least $\max(1, n)$.
 If $jobz = 'U'$, then the matrix z is multiplied by Q .
 If $jobz = 'N'$ or $'V'$, then z is not referenced.
 $work(lwork)$ is a workspace array.
 lda INTEGER. The first dimension of a ; at least $\max(1, n)$.
 ldz INTEGER. The first dimension of z ; at least $\max(1, n)$. Not referenced if $jobz = 'N'$.
 $lwork$ INTEGER. The size of the $work$ array ($lwork \geq (2kd+1)n+kd$).
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a If $jobz = 'V'$, then overwritten by Q matrix.
 If $jobz = 'N'$ or $'U'$, then overwritten by the banded matrix B and details of the unitary matrix Q_B to reduce A to B as specified by $uplo$.
 z On exit,
 if $jobz = 'U'$, then the matrix z is overwritten by Z^*Q .
 If $jobz = 'N'$ or $'V'$, then z is not referenced.
 d, e COMPLEX for cherdb.
 DOUBLE COMPLEX for zherdb.
 Arrays:
 $d(*)$ contains the diagonal elements of the matrix T .
 The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of T .
 The dimension of e must be at least $\max(1, n-1)$.
 $tau(*)$ stores further details of the orthogonal matrix Q .

	The dimension of <i>tau</i> must be at least $\max(1, n-kd-1)$.
<i>tau</i>	COMPLEX for <i>cherdb</i> . DOUBLE COMPLEX for <i>zherdb</i> . Array, DIMENSION at least $\max(1, n-1)$ Stores further details of the unitary matrix Q_B . The dimension of <i>tau</i> must be at least $\max(1, n-kd-1)$.
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Application Notes

For better performance, try using $lwork = n*(3*kd+3)$.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using *kd* equal to 40 if $n \leq 2000$ and 64 otherwise.

Try using *?herdb* instead of *?hetrd* on large matrices obtaining only eigenvalues - when no eigenvectors are needed, especially in multi-threaded environment. *?herdb* becomes faster beginning approximately with $n = 1000$, and much faster at larger matrices with a better scalability than *?hetrd*.

Avoid applying `?herdb` for computing eigenvectors due to the two-step reduction, that is, the number of operations needed to apply orthogonal transformations to z is doubled compared to the traditional one-step reduction. In that case it is better to apply `?hetrd` and `?unmtr/?ungtr` to obtain tridiagonal form along with the unitary transformation matrix Q .

?orgtr

Generates the real orthogonal matrix Q determined by ?sytrd.

Syntax

FORTRAN 77:

```
call sorgtr(uplo, n, a, lda, tau, work, lwork, info)
```

```
call dorgtr(uplo, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgtr(a, tau [,uplo] [,info])
```

Description

The routine explicitly generates the n -by- n orthogonal matrix Q formed by `?sytrd` when reducing a real symmetric matrix A to tridiagonal form: $A = Q^T Q$. Use this routine after a call to `?sytrd`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Use the same <code>uplo</code> as supplied to <code>?sytrd</code> .
<code>n</code>	INTEGER. The order of the matrix Q ($n \geq 0$).
<code>a, tau, work</code>	REAL for <code>sorgtr</code> DOUBLE PRECISION for <code>dorgtr</code> . Arrays: <code>a(lda,*)</code> is the array <code>a</code> as returned by <code>?sytrd</code> . The second dimension of <code>a</code> must be at least $\max(1, n)$. <code>tau(*)</code> is the array <code>tau</code> as returned by <code>?sytrd</code> . The dimension of <code>tau</code> must be at least $\max(1, n-1)$. <code>work</code> is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array ($lwork \geq n$).
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by the orthogonal matrix *Q*.

work(1) If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgtr` interface are the following:

a Holds the matrix *A* of size (n, n) .

tau Holds the vector of length $(n-1)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = (n-1) * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

The complex counterpart of this routine is `?ungtr`.

`?ormtr`

Multiplies a real matrix by the real orthogonal matrix Q determined by `?sytrd`.

Syntax

FORTRAN 77:

```
call sormtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
call dormtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by `?sytrd` when reducing a real symmetric matrix A to tridiagonal form: $A = Q^T Q$. Use this routine after a call to `?sytrd`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If $side = 'L'$, Q or Q^T is applied to C from the left. If $side = 'R'$, Q or Q^T is applied to C from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?sytrd.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If $trans = 'N'$, the routine multiplies C by Q. If $trans = 'T'$, the routine multiplies C by Q^T.
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>a, c, tau, work</i>	REAL for sormtr DOUBLE PRECISION for dormtr $a(lda,*)$ and tau are the arrays returned by ?sytrd. The second dimension of a must be at least $\max(1, r)$. The dimension of tau must be at least $\max(1, r-1)$. $c(ldc,*)$ contains the matrix C. The second dimension of c must be at least $\max(1, n)$ $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, r)$.
<i>ldc</i>	INTEGER. The first dimension of c ; $ldc \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if $side = 'L'$; $lwork \geq \max(1, m)$ if $side = 'R'$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , $Q^T C$, C^*Q , or C^*Q^T (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormtr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>r</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>r</i> -1).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using *lwork* = *n*blocksize* for *side* = 'L', or *lwork* = *m*blocksize* for *side* = 'R', where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|^2 = O(\epsilon) * \|C\|^2$.

The total number of floating-point operations is approximately $2*m^2*n$, if `side = 'L'`, or $2*n^2*m$, if `side = 'R'`.

The complex counterpart of this routine is [?unmtr](#).

?hetrd

Reduces a complex Hermitian matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call chetrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
call zhetrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
```

Fortran 95:

```
call hetrd(a, tau [,uplo] [,info])
```

Description

This routine reduces a complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q * T * Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided to work with Q in this representation. (They are described later in this section.)

This routine calls [?latrd](#) to reduce a complex Hermitian matrix A to Hermitian tridiagonal form by a unitary similarity transformation.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	COMPLEX for <code>chetrd</code> DOUBLE COMPLEX for <code>zhetr</code> d. <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the tridiagonal matrix <i>T</i> and details of the unitary matrix <i>Q</i> , as specified by <i>uplo</i> .
<i>d, e</i>	REAL for <code>chetrd</code> DOUBLE PRECISION for <code>zhetr</code> d. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$.
<i>tau</i>	COMPLEX for <code>chetrd</code> DOUBLE COMPLEX for <code>zhetr</code> d. Array, DIMENSION at least $\max(1, n-1)$. Stores further details of the unitary matrix <i>Q</i> .

<code>work(1)</code>	If <code>info = 0</code> , on exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance. Use this <code>lwork</code> for subsequent runs.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = -i</code> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrd` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size (n, n) .
<code>tau</code>	Holds the vector of length $(n-1)$.
<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length $(n-1)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using `lwork = n*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

After calling this routine, you can call the following:

`?ungtr` to form the computed matrix Q explicitly
`?unmtr` to multiply a complex matrix by Q .

The real counterpart of this routine is `?sytrd`.

?ungtr

Generates the complex unitary matrix Q determined by ?hetrd.

Syntax

FORTRAN 77:

```
call cungr( uplo, n, a, lda, tau, work, lwork, info)
call zungtr( uplo, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungtr(a, tau [,uplo] [,info])
```

Description

The routine explicitly generates the n -by- n unitary matrix Q formed by `?hetrd` when reducing a complex Hermitian matrix A to tridiagonal form: $A = Q^* T^* Q^H$. Use this routine after a call to `?hetrd`.

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.
 Use the same `uplo` as supplied to `?hetrd`.

`n` INTEGER. The order of the matrix Q ($n \geq 0$).

`a, tau, work` COMPLEX for `cungr`
 DOUBLE COMPLEX for `zungtr`.

Arrays:

$a(lda,*)$ is the array a as returned by `?hetrd`.
The second dimension of a must be at least $\max(1, n)$.
 $tau(*)$ is the array tau as returned by `?hetrd`.
The dimension of tau must be at least $\max(1, n-1)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
 lda INTEGER. The first dimension of a ; at least $\max(1, n)$.
 $lwork$ INTEGER. The size of the $work$ array ($lwork \geq n$).
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the unitary matrix Q .
 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
 $info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungtr` interface are the following:

a Holds the matrix A of size (n, n) .
 tau Holds the vector of length $(n-1)$.
 $uplo$ Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = (n-1)*blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

The real counterpart of this routine is [?orgtr](#).

?unmtr

Multiplies a complex matrix by the complex unitary matrix Q determined by ?hetrd.

Syntax

FORTRAN 77:

```
call cunmtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
call zunmtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix Q formed by `?hetrd` when reducing a complex Hermitian matrix A to tridiagonal form: $A = Q^* T^* Q^H$. Use this routine after a call to `?hetrd`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , Q^H^*C , C^*Q , or C^*Q^H (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to <code>?hetrd</code> .
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	COMPLEX for <code>cunmtr</code> DOUBLE COMPLEX for <code>zunmtr</code> . <i>a</i> (<i>lda</i> ,*) and <i>tau</i> are the arrays returned by <code>?hetrd</code> . The second dimension of <i>a</i> must be at least $\max(1, r)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, r)$.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints:

$lwork \geq \max(1, n)$ if $side = 'L'$;

$lwork \geq \max(1, m)$ if $side = 'R'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , $Q^H * C$, C^*Q , or C^*Q^H (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmtr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>r</i>). $r = m$ if $side = 'L'$. $r = n$ if $side = 'R'$.
<i>tau</i>	Holds the vector of length (<i>r</i> -1).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (for $side = 'L'$) or $lwork = m * blocksize$ (for $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $8 * m^2 * n$ if $side = 'L'$ or $8 * n^2 * m$ if $side = 'R'$.

The real counterpart of this routine is [?ormtr](#).

?sptd

Reduces a real symmetric matrix to tridiagonal form using packed storage.

Syntax

FORTRAN 77:

```
call ssptd(uplo, n, ap, d, e, tau, info)
call dsptd(uplo, n, ap, d, e, tau, info)
```

Fortran 95:

```
call sptd(a, tau [,uplo] [,info])
```

Description

This routine reduces a packed real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^* T^* Q^T$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ap* stores the packed upper triangle of A .
 If *uplo* = 'L', *ap* stores the packed lower triangle of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

ap REAL for ssptrd
 DOUBLE PRECISION for dsptrd.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by *uplo*) in packed form.

Output Parameters

ap Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by *uplo*.

d, *e*, *tau* REAL for ssptrd
 DOUBLE PRECISION for dsptrd.
 Arrays:
d(*) contains the diagonal elements of the matrix T .
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of T .
 The dimension of *e* must be at least $\max(1, n-1)$.
tau(*) stores further details of the matrix Q .
 The dimension of *tau* must be at least $\max(1, n-1)$.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptprd` interface are the following:

<code>a</code>	Stands for argument <code>ap</code> in Fortran 77 interface. Holds the array <code>A</code> of size $(n * (n+1) / 2)$.
<code>tau</code>	Holds the vector of length $(n-1)$.
<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length $(n-1)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The approximate number of floating-point operations is $(4/3) n^3$.

After calling this routine, you can call the following:

<code>?opgtr</code>	to form the computed matrix Q explicitly
<code>?opmtr</code>	to multiply a real matrix by Q .

The complex counterpart of this routine is [?hptprd](#).

?opgtr

Generates the real orthogonal matrix Q determined by ?sptprd.

Syntax

FORTRAN 77:

```
call sopgtr(uplo, n, ap, tau, q, ldq, work, info)
call dopgtr(uplo, n, ap, tau, q, ldq, work, info)
```

Fortran 95:

```
call opgtr(a, tau, q [,uplo] [,info])
```

Description

The routine explicitly generates the n -by- n orthogonal matrix Q formed by ?sptdr when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^*T^*Q^T$. Use this routine after a call to ?sptdr.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'. Use the same *uplo* as supplied to ?sptdr.

n INTEGER. The order of the matrix Q ($n \geq 0$).

ap, tau REAL for sopgtr
DOUBLE PRECISION for dopgtr.
Arrays *ap* and *tau*, as returned by ?sptdr.
The dimension of *ap* must be at least $\max(1, n(n+1)/2)$.
The dimension of *tau* must be at least $\max(1, n-1)$.

ldq INTEGER. The first dimension of the output array q_i at least $\max(1, n)$.

work REAL for sopgtr
DOUBLE PRECISION for dopgtr.
Workspace array, DIMENSION at least $\max(1, n-1)$.

Output Parameters

q REAL for sopgtr
DOUBLE PRECISION for dopgtr.
Array, DIMENSION (*ldq*,*).
Contains the computed matrix Q .
The second dimension of *q* must be at least $\max(1, n)$.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `opgtr` interface are the following:

<code>a</code>	Stands for argument <code>ap</code> in Fortran 77 interface. Holds the array <code>A</code> of size $(n * (n + 1) / 2)$.
<code>tau</code>	Holds the vector of length $(n - 1)$.
<code>q</code>	Holds the matrix <code>Q</code> of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed matrix `Q` differs from an exactly orthogonal matrix by a matrix `E` such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

The complex counterpart of this routine is [?upgtr](#).

?opmtr

Multiplies a real matrix by the real orthogonal matrix `Q` determined by ?sptrd.

Syntax

FORTRAN 77:

```
call sopmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
call dopmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
```

Fortran 95:

```
call opmtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by `?sptdr` when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^T T Q$. Use this routine after a call to `?sptdr`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to <code>?sptdr</code> .
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>ap</i> , <i>tau</i> , <i>c</i> , <i>work</i>	REAL for <code>sopmtr</code> DOUBLE PRECISION for <code>dopmtr</code> . <i>ap</i> and <i>tau</i> are the arrays returned by <code>?sptdr</code> . The dimension of <i>ap</i> must be at least $\max(1, r(r+1)/2)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c(ldc,*)</i> contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$. <i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$ if <i>side</i> = 'L'; $\max(1, m)$ if <i>side</i> = 'R'.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, n)$.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (as specified by <i>side</i> and <i>trans</i>).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `opmtr` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(r*(r+1)/2)$, where $r = m$ if <i>side</i> = 'L'. $r = n$ if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length $(r-1)$.
<i>c</i>	Holds the matrix <i>C</i> of size (m,n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\epsilon)$ $\|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $2*m^2*n$ if *side* = 'L', or $2*n^2*m$ if *side* = 'R'.

The complex counterpart of this routine is [?upmtr](#).

?hptrd

Reduces a complex Hermitian matrix to tridiagonal form using packed storage.

Syntax

FORTRAN 77:

```
call chptrd(uplo, n, ap, d, e, tau, info)
call zhptrd(uplo, n, ap, d, e, tau, info)
```

Fortran 95:

```
call hptrd(a, tau [,uplo] [,info])
```

Description

This routine reduces a packed complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^* T^* Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangle of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangle of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap</i>	COMPLEX for <i>chptrd</i> DOUBLE COMPLEX for <i>zhptrd</i> . Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by <i>uplo</i>) in packed form.

Output Parameters

<i>ap</i>	Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by <i>uplo</i> .
<i>d</i> , <i>e</i>	REAL for <i>chptrd</i> DOUBLE PRECISION for <i>zhptrd</i> .

Arrays:
 $d(*)$ contains the diagonal elements of the matrix T .
 The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of T .
 The dimension of e must be at least $\max(1, n-1)$.

tau COMPLEX for `chptrd`
 DOUBLE COMPLEX for `zhptrd`.
 Arrays, DIMENSION at least $\max(1, n-1)$. Contains further
 details of the orthogonal matrix Q .

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrd` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
<i>tau</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length (n) .
<i>e</i>	Holds the vector of length $(n-1)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3) n^3$.

After calling this routine, you can call the following:

<code>?upgtr</code>	to form the computed matrix Q explicitly
<code>?upmtr</code>	to multiply a complex matrix by Q .

The real counterpart of this routine is `?sptrd`.

?upgtr

Generates the complex unitary matrix Q determined by ?hptrd.

Syntax

FORTRAN 77:

```
call cupgtr(uplo, n, ap, tau, q, ldq, work, info)
call zupgtr(uplo, n, ap, tau, q, ldq, work, info)
```

Fortran 95:

```
call upgtr(a, tau, q [,uplo] [,info])
```

Description

The routine explicitly generates the n -by- n unitary matrix Q formed by ?hptrd when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q^* T^* Q^H$. Use this routine after a call to ?hptrd.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?hptrd.
<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>ap, tau</i>	COMPLEX for cupgtr DOUBLE COMPLEX for zupgtr. Arrays <i>ap</i> and <i>tau</i> , as returned by ?hptrd. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The dimension of <i>tau</i> must be at least $\max(1, n-1)$.
<i>ldq</i>	INTEGER. The first dimension of the output array <i>q</i> ; at least $\max(1, n)$.
<i>work</i>	COMPLEX for cupgtr DOUBLE COMPLEX for zupgtr. Workspace array, DIMENSION at least $\max(1, n-1)$.

Output Parameters

<i>q</i>	COMPLEX for <code>cupgtr</code> DOUBLE COMPLEX for <code>zupgtr</code> . Array, DIMENSION (<i>ldq</i> ,*). Contains the computed matrix <i>Q</i> . The second dimension of <i>q</i> must be at least $\max(1, n)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `upgtr` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>tau</i>	Holds the vector of length $(n - 1)$.
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\varepsilon)$, where ε is the machine precision.

The approximate number of floating-point operations is $(16/3) n^3$.

The real counterpart of this routine is `?opgtr`.

?upmtr

Multiplies a complex matrix by the unitary matrix Q determined by ?hptrd.

Syntax

FORTRAN 77:

```
call cupmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
call zupmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
```

Fortran 95:

```
call upmtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix formed by ?hptrd when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q^* T Q^H$. Use this routine after a call to ?hptrd.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^* C$, $Q^H C$, $C Q$, or $C Q^H$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If *side* = 'L', $r = m$; if *side* = 'R', $r = n$.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?hptrd.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).

ap, *tau*, *c*,
 COMPLEX for `cupmtr`
 DOUBLE COMPLEX for `zupmtr`.
ap and *tau* are the arrays returned by `?hptrd`.
 The dimension of *ap* must be at least $\max(1, r(r+1)/2)$.
 The dimension of *tau* must be at least $\max(1, r-1)$.
c(ldc,)* contains the matrix *C*.
 The second dimension of *c* must be at least $\max(1, n)$
work()* is a workspace array.
 The dimension of *work* must be at least
 $\max(1, n)$ if *side* = 'L';
 $\max(1, m)$ if *side* = 'R'.
ldc
 INTEGER. The first dimension of *c*; $ldc \geq \max(1, n)$.

Output Parameters

c
 Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by *side* and *trans*).
info
 INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `upmtr` interface are the following:

a
 Stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size $(r*(r+1)/2)$, where
 $r = m$ if *side* = 'L'.
 $r = n$ if *side* = 'R'.
tau
 Holds the vector of length $(r-1)$.
c
 Holds the matrix *C* of size (m, n) .
side
 Must be 'L' or 'R'. The default value is 'L'.
uplo
 Must be 'U' or 'L'. The default value is 'U'.
trans
 Must be 'N' or 'C'. The default value is 'N'.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if $side = 'L'$ or $8*n^2*m$ if $side = 'R'$.

The real counterpart of this routine is `?opmtr`.

?sbtrd

Reduces a real symmetric band matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call ssbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
call dsbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
```

Fortran 95:

```
call sbtrd(a [, q] [, vect] [, uplo] [, info])
```

Description

This routine reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q*T*Q^T$. The orthogonal matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

<code>vect</code>	CHARACTER*1. Must be 'V' or 'N'. If <code>vect = 'V'</code> , the routine returns the explicit matrix Q . If <code>vect = 'N'</code> , the routine does not return Q .
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>ab</code> stores the upper triangular part of A . If <code>uplo = 'L'</code> , <code>ab</code> stores the lower triangular part of A .

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).
<i>ab, work</i>	REAL for ssbtrd DOUBLE PRECISION for dsbtrd. <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> ; at least $kd+1$.
<i>ldq</i>	INTEGER. The first dimension of <i>q</i> . Constraints: $ldq \geq \max(1, n)$ if <i>vect</i> = 'V'; $ldq \geq 1$ if <i>vect</i> = 'N'.

Output Parameters

<i>ab</i>	On exit, the array <i>ab</i> is overwritten.
<i>d, e, q</i>	REAL for ssbtrd DOUBLE PRECISION for dsbtrd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>q</i> (<i>ldq</i> ,*) is not referenced if <i>vect</i> = 'N'. If <i>vect</i> = 'V', <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix <i>Q</i> . The second dimension of <i>q</i> must be: at least $\max(1, n)$ if <i>vect</i> = 'V'; at least 1 if <i>vect</i> = 'N'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbtrd` interface are the following:

<code>a</code>	Stands for argument <code>ab</code> in Fortran 77 interface. Holds the array <code>A</code> of size $(kd+1, n)$.
<code>q</code>	Holds the matrix <code>Q</code> of size (n, n) .
<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length $(n-1)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>vect</code>	If omitted, this argument is restored based on the presence of argument <code>q</code> as follows: <code>vect</code> = 'V', if <code>q</code> is present, <code>vect</code> = 'N', if <code>q</code> is omitted. If present, <code>vect</code> must be equal to 'V' or 'U' and the argument <code>q</code> must also be present. Note that there will be an error condition if <code>vect</code> is present and <code>q</code> omitted.

Application Notes

The computed matrix `T` is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The computed matrix `Q` differs from an exactly orthogonal matrix by a matrix `E` such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $6n^2 * kd$ if `vect` = 'N', with $3n^3 * (kd-1) / kd$ additional operations if `vect` = 'V'.

The complex counterpart of this routine is [?hbtrd](#).

?hbtrd

Reduces a complex Hermitian band matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call chbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
call zhbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
```

Fortran 95:

```
call hbtrd(a [, q] [,vect] [,uplo] [,info])
```

Description

This routine reduces a complex Hermitian band matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^* T Q^H$. The unitary matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>vect</i> = 'V', the routine returns the explicit matrix Q . If <i>vect</i> = 'N', the routine does not return Q .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in A ($kd \geq 0$).
<i>ab, work</i>	COMPLEX for chbtrd DOUBLE COMPLEX for zhbtrd. <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the matrix A (as specified by <i>uplo</i>) in band storage format.

The second dimension of *ab* must be at least $\max(1, n)$.
work(*) is a workspace array.
 The dimension of *work* must be at least $\max(1, n)$.
ldab INTEGER. The first dimension of *ab*; at least $kd+1$.
ldq INTEGER. The first dimension of *q*. Constraints:
 $ldq \geq \max(1, n)$ if *vect* = 'V';
 $ldq \geq 1$ if *vect* = 'N'.

Output Parameters

ab On exit, the array *ab* is overwritten.
d, e REAL for *chbtrd*
 DOUBLE PRECISION for *zhbtrd*.
 Arrays:
d(*) contains the diagonal elements of the matrix *T*.
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of *T*.
 The dimension of *e* must be at least $\max(1, n-1)$.
q COMPLEX for *chbtrd*
 DOUBLE COMPLEX for *zhbtrd*.
 Array, DIMENSION (*ldq*,*).
 If *vect* = 'N', *q* is not referenced.
 If *vect* = 'V', *q* contains the *n*-by-*n* matrix *Q*.
 The second dimension of *q* must be:
 at least $\max(1, n)$ if *vect* = 'V';
 at least 1 if *vect* = 'N'.
info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hbtrd* interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>d</i>	Holds the vector of length (n) .
<i>e</i>	Holds the vector of length $(n-1)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vect</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>vect</i> = 'V', if <i>q</i> is present, <i>vect</i> = 'N', if <i>q</i> is omitted. If present, <i>vect</i> must be equal to 'V' or 'U' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>vect</i> is present and <i>q</i> omitted.

Application Notes

The computed matrix *T* is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $20n^2 * kd$ if *vect* = 'N', with $10n^3 * (kd-1) / kd$ additional operations if *vect* = 'V'.

The real counterpart of this routine is [?sbtrd](#).

?sterf

Computes all eigenvalues of a real symmetric tridiagonal matrix using QR algorithm.

Syntax

FORTRAN 77:

```
call ssterf(n, d, e, info)
call dsterf(n, d, e, info)
```

Fortran 95:

```
call sterf(d, e [,info])
```

Description

This routine computes all the eigenvalues of a real symmetric tridiagonal matrix T (which can be obtained by reducing a symmetric or Hermitian matrix to tridiagonal form). The routine uses a square-root-free variant of the QR algorithm.

If you need not only the eigenvalues but also the eigenvectors, call [?stegr](#).

Input Parameters

n INTEGER. The order of the matrix T ($n \geq 0$).

d, e REAL for `ssterf`
DOUBLE PRECISION for `dsterf`.
Arrays:
 $d(*)$ contains the diagonal elements of T .
The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of T .
The dimension of e must be at least $\max(1, n-1)$.

Output Parameters

d The n eigenvalues in ascending order, unless $info > 0$.
See also $info$.

e On exit, the array is overwritten; see $info$.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations:
 i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sterf` interface are the following:

d Holds the vector of length (*n*).

e Holds the vector of length (*n*-1).

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and m_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about $14n^2$.

?steqr

Computes all eigenvalues and eigenvectors of a symmetric or Hermitian matrix reduced to tridiagonal form (QR algorithm).

Syntax

FORTRAN 77:

```
call ssteqr(compz, n, d, e, z, ldz, work, info)
call dsteqr(compz, n, d, e, z, ldz, work, info)
call csteqr(compz, n, d, e, z, ldz, work, info)
call zsteqr(compz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call rsteqr(d, e [,z] [,compz] [,info])
call steqr(d, e [,z] [,compz] [,info])
```

Description

This routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z^* \Lambda Z^T$. Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^* Z_i = \lambda_i^* Z_i \text{ for } i = 1, 2, \dots, n.$$

The routine normalizes the eigenvectors so that $\|Z_i\|_2 = 1$.

You can also use the routine for computing the eigenvalues and eigenvectors of an arbitrary real symmetric (or complex Hermitian) matrix A reduced to tridiagonal form T : $A = Q^* T Q^H$.

In this case, the spectral factorization is as follows: $A = Q^* T Q^H = (Q^* Z)^* \Lambda^* (Q^* Z)^H$. Before calling `?steqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

	for real matrices:	for complex matrices:
full storage	<code>?sytrd</code> , <code>?orgtr</code>	<code>?hetrd</code> , <code>?ungtr</code>
packed storage	<code>?sptrd</code> , <code>?opgtr</code>	<code>?hptrd</code> , <code>?upgtr</code>
band storage	<code>?sbtrd</code> (<code>vect='V'</code>)	<code>?hbtrd</code> (<code>vect='V'</code>)

If you need eigenvalues only, it's more efficient to call `?sterf`. If T is positive-definite, `?pteqr` can compute small eigenvalues more accurately than `?steqr`.

To solve the problem by a single call, use one of the divide and conquer routines `?stevd`, `?syevd`, `?spevd`, or `?sbevd` for real symmetric matrices or `?heevd`, `?hpevd`, or `?hbevd` for complex Hermitian matrices.

Input Parameters

compz

CHARACTER*1. Must be 'N' or 'I' or 'V'.

If *compz* = 'N', the routine computes eigenvalues only.

If *compz* = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T .

If *compz* = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array z must contain the matrix Q on entry).

n	INTEGER. The order of the matrix T ($n \geq 0$).
$d, e, work$	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: $d(*)$ contains the diagonal elements of T . The dimension of d must be at least $\max(1, n)$. $e(*)$ contains the off-diagonal elements of T . The dimension of e must be at least $\max(1, n-1)$. $work(*)$ is a workspace array. The dimension of $work$ must be: at least 1 if $compz = 'N'$; at least $\max(1, 2*n-2)$ if $compz = 'V'$ or $'I'$.
z	REAL for ssteqr DOUBLE PRECISION for dsteqr COMPLEX for csteqr DOUBLE COMPLEX for zsteqr. Array, DIMENSION ($ldz, *$) If $compz = 'N'$ or $'I'$, z need not be set. If $vect = 'V'$, z must contain the n -by- n matrix Q . The second dimension of z must be: at least 1 if $compz = 'N'$; at least $\max(1, n)$ if $compz = 'V'$ or $'I'$. $work(lwork)$ is a workspace array.
ldz	INTEGER. The first dimension of z . Constraints: $ldz \geq 1$ if $compz = 'N'$; $ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

Output Parameters

d	The n eigenvalues in ascending order, unless $info > 0$. See also $info$.
e	On exit, the array is overwritten; see $info$.
z	If $info = 0$, contains the n orthonormal eigenvectors, stored by columns. (The i -th column corresponds to the i th eigenvalue.)
$info$	INTEGER.

If $info = 0$, the execution is successful.
 If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations: i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `steqr` interface are the following:

d	Holds the vector of length (n) .
e	Holds the vector of length $(n-1)$.
z	Holds the matrix z of size (n, n) .
$compz$	If omitted, this argument is restored based on the presence of argument z as follows: $compz = 'I'$, if z is present, $compz = 'N'$, if z is omitted. If present, $compz$ must be equal to 'I' or 'V' and the argument z must also be present. Note that there will be an error condition if $compz$ is present and z omitted. Note that two variants of Fortran 95 interface for <code>steqr</code> routine are needed because of an ambiguous choice between real and complex cases appear when z is omitted. Thus, the name <code>rsteqr</code> is used in real cases (single or double precision), and the name <code>steqr</code> is used in complex cases (single or double precision).

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about

$24n^2$ if `compz = 'N'`;

$7n^3$ (for complex flavors, $14n^3$) if `compz = 'V' or 'I'`.

stemr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)

call dstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)

call cstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)

call zstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices `il:iu` for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the *dqds* algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable $L^*D^*L^T$ factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T ,

- a.** Compute $T - \sigma I = L^*D^*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of L and D cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see steps c and d.
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to step c for any clusters that remain.

For more details, see: [Dhillon04], [Dhillon04-02], [Dhillon97]

The routine works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs (NaN stands for "not a number"). This permits the use of efficient inner loops avoiding a check for zero divisors.

LAPACK routines can be used to reduce a complex Hermitean matrix to real symmetric tridiagonal form.

(Any complex Hermitean tridiagonal matrix has real values on its diagonal and potentially complex numbers on its off-diagonals. By applying a similarity transform with an appropriate diagonal matrix $\text{diag}(1, e^{i\phi_1}, \dots, e^{i\phi_{n-1}})$, the complex Hermitean matrix can be transformed into a real symmetric matrix and complex arithmetic can be entirely avoided.) While the eigenvectors of the real symmetric tridiagonal matrix are real, the eigenvectors of original complex Hermitean matrix have complex entries in general. Since LAPACK drivers overwrite the matrix data with the eigenvectors, *zstemr* accepts complex workspace to facilitate interoperability with *zunmtr* or *zupmtr*.

Input Parameters

jobz CHARACTER*1. Must be 'N' or 'V'.
If *jobz* = 'N', then only eigenvalues are computed.

	If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes all eigenvalues in the half-open interval: (<i>vl</i>, <i>vu</i>]. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>n</i>	INTEGER. The order of the matrix <i>T</i> (<i>n</i>≥0).
<i>d</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>.
<i>e</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>-1). Contains (<i>n</i>-1) off-diagonal elements of the tridiagonal matrix <i>T</i> in elements 1 to <i>n</i>-1 of <i>e</i>. <i>e</i>(<i>n</i>) need not be set on input, but is used internally as workspace.
<i>vl, vu</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: <i>vl</i><<i>vu</i>. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: 1≤<i>il</i>≤<i>iu</i>≤<i>n</i>, if <i>n</i>>0. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. if <i>jobz</i> = 'V', then <i>ldz</i> ≥ max(1, <i>n</i>); <i>ldz</i> ≥ 1 otherwise.
<i>nzc</i>	INTEGER. The number of eigenvectors to be held in the array <i>z</i>. If <i>range</i> = 'A', then <i>nzc</i>≥max(1, <i>n</i>);

If *range* = 'V', then *nzc* is greater than or equal to the number of eigenvalues in the half-open interval: (*vl*, *vu*].

If *range* = 'I', then $nzc \geq il + iu + 1$.

This value is returned as the first entry of the array *z*, and no error message related to *nzc* is issued by the routine *xerbla*.

tryrac

LOGICAL.

If *tryrac* = .TRUE., it indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can use possibly faster algorithms.

If *tryrac* = .FALSE., the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques.

work

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION (*lwork*).

lwork

INTEGER.

The dimension of the array *work*,

$lwork \geq \max(1, 18 * n)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

iwork

INTEGER.

Workspace array, DIMENSION (*liwork*).

liwork

INTEGER.

The dimension of the array *iwork*.

$lwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and

$lwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by xerbla.

Output Parameters

<i>e</i>	On exit, the array <i>e</i> is overwritten.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', then $m=n$, and if <i>range</i> = 'I', then $m=iu-il+1$.
<i>w</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The first <i>m</i> elements contain the selected eigenvalues in ascending order.
<i>z</i>	REAL for sstemr DOUBLE PRECISION for dstemr COMPLEX for cstemr DOUBLE COMPLEX for zstemr. Array <i>z</i>(<i>ldz</i>, *), the second dimension of <i>z</i> must be at least $\max(1, m)$. If <i>jobz</i> = 'V', and <i>info</i> = 0, then the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>T</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w</i>(<i>i</i>). If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i>; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and can be computed with a workspace query by setting <i>nzc</i> = -1, see description of the parameter <i>nzc</i>.
<i>isuppz</i>	INTEGER. Array, DIMENSION ($2 * \max(1, m)$).

	The support of the eigenvectors in <i>z</i> , that is the indices indicating the nonzero elements in <i>z</i> . The <i>i</i> -th computed eigenvector is nonzero only in elements <i>isuppz</i> (2*i-1) through <i>isuppz</i> (2*i). This is relevant in the case when the matrix is split. <i>isuppz</i> is only accessed when <i>jobz</i> = 'V' and <i>n</i> >0.
<i>tryrac</i>	On exit, TRUE. <i>tryrac</i> is set to .FALSE. if the matrix does not define its eigenvalues to high relative accuracy.
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the optimal (and minimal) size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the optimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If = 0, the execution is successful. If <i>info</i> = -i, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, internal error in ?larre occurred, if <i>info</i> = 2, internal error in ?larrv occurred.

?stedc

Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Syntax

FORTRAN 77:

```
call sstedc(compz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
call dstedc(compz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
call cstedc(compz, n, d, e, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
call zstedc(compz, n, d, e, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call rstedc(d, e [,z] [,compz] [,info])
```

```
call stedc(d, e [,z] [,compz] [,info])
```

Description

This routine computes all the eigenvalues and (optionally) all the eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric or complex Hermitian matrix can also be found if [?sytrd/?hetrd](#) or [?sptrd/?hptrd](#) or [?sbtrd/?hbtrd](#) has been used to reduce this matrix to tridiagonal form.

See also [?laed0](#), [?laed1](#), [?laed2](#), [?laed3](#), [?laed4](#), [?laed5](#), [?laed6](#), [?laed7](#), [?laed8](#), [?laed9](#), and [?laeda](#) used by this function.

Input Parameters

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix. If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of original symmetric/Hermitian matrix. On entry, the array <i>z</i> must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The order of the symmetric tridiagonal matrix ($n \geq 0$).
<i>d, e, rwork</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i>(*) contains the diagonal elements of the tridiagonal matrix. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i>(*) contains the subdiagonal elements of the tridiagonal matrix. The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>rwork</i> is a workspace array, its dimension $\max(1, lrwork)$.
<i>z, work</i>	REAL for sstedc DOUBLE PRECISION for dstedc

COMPLEX for `cstedc`
 DOUBLE COMPLEX for `zstedc`.
 Arrays: `z(ldz, *)`, `work(*)`.
 If `compz = 'V'`, then, on entry, `z` must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.
 The second dimension of `z` must be at least $\max(1, n)$.
`work` is a workspace array, its dimension $\max(1, lwork)$.

`ldz` INTEGER. The first dimension of `z`. Constraints:
 $ldz \geq 1$ if `compz = 'N'`;
 $ldz \geq \max(1, n)$ if `compz = 'V' or 'I'`.

`lwork` INTEGER. The dimension of the array `work`.
 If `compz = 'N' or 'I'`, or $n \leq 1$, `lwork` must be at least 1.
 If `compz = 'V'` and $n > 1$, `lwork` must be at least $n*n$.
 Note that for `compz = 'V'`, and if n is less than or equal to the minimum divide size, usually 25, then `lwork` need only be 1.
 If `lwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work`, `rwork` and `iwork` arrays, returns these values as the first entries of the `work`, `rwork` and `iwork` arrays, and no error message related to `lwork` or `lrwork` or `liwork` is issued by [xerbla](#). See *Application Notes* for the required value of `lwork`.

`lrwork` INTEGER. The dimension of the array `rwork` (used for complex flavors only).
 If `compz = 'N'`, or $n \leq 1$, `lrwork` must be at least 1.
 If `compz = 'V'` and $n > 1$, `lrwork` must be at least $(1+3*n+2*n*\lg(n)+3*n*n)$, where $\lg(n)$ is the smallest integer k such that $2^{**k} \geq n$.
 If `compz = 'I'` and $n > 1$, `lrwork` must be at least $(1+4*n+2*n*n)$.
 Note that for `compz = 'V' or 'I'`, and if n is less than or equal to the minimum divide size, usually 25, then `lrwork` need only be $\max(1, 2*(n-1))$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for the required value of *lrwork*.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER. The dimension of the array *iwork*.

If $compz = 'N'$, or $n \leq 1$, *liwork* must be at least 1.

If $compz = 'V'$ and $n > 1$, *liwork* must be at least $(6+6*n+5*n*\lg(n))$, where $\lg(n)$ is the smallest integer k such that $2^{**k} \geq n$.

If $compz = 'I'$ and $n > 1$, *liwork* must be at least $(3+5*n)$.

Note that for $compz = 'V'$ or $'I'$, and if n is less than or equal to the minimum divide size, usually 25, then *liwork* need only be 1.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for the required value of *liwork*.

Output Parameters

d The n eigenvalues in ascending order, unless *info* $\neq 0$. See also *info*.

e On exit, the array is overwritten; see *info*.

z If *info* = 0, then if $compz = 'V'$, *z* contains the orthonormal eigenvectors of the original symmetric/Hermitian matrix, and if $compz = 'I'$, *z* contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $compz = 'N'$, *z* is not referenced.

work(1) On exit, if *info* = 0, then *work*(1) returns the optimal *lwork*.

<i>rwork(1)</i>	On exit, if <i>info</i> = 0, then <i>rwork(1)</i> returns the optimal <i>lrwork</i> (for complex flavors only).
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the optimal <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>i</i> /(<i>n</i> +1) through mod(<i>i</i> , <i>n</i> +1).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stedc` interface are the following:

<i>d</i>	Holds the vector of length (<i>n</i>).
<i>e</i>	Holds the vector of length (<i>n</i> -1).
<i>z</i>	Holds the matrix <i>z</i> of size (<i>n</i> , <i>n</i>).
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument <i>z</i> must also be present. Note that there will be an error condition if <i>compz</i> is present and <i>z</i> omitted.

Note that two variants of Fortran 95 interface for `stedc` routine are needed because of an ambiguous choice between real and complex cases appear when *z* and *work* are omitted. Thus, the name `rstedc` is used in real cases (single or double precision), and the name `stedc` is used in complex cases (single or double precision).

Application Notes

The required size of workspace arrays must be as follows.

For `sstedc/dstedc`:

If *compz* = 'N' or *n* ≤ 1 then *lwork* must be at least 1.

If `compz = 'V'` and $n > 1$ then `lwork` must be at least $(1 + 3n + 2n \cdot \lg n + 3n^2)$, where $\lg(n)$ = smallest integer k such that $2^k \geq n$.

If `compz = 'I'` and $n > 1$ then `lwork` must be at least $(1 + 4n + n^2)$.

If `compz = 'N'` or $n \leq 1$ then `liwork` must be at least 1.

If `compz = 'V'` and $n > 1$ then `liwork` must be at least $(6 + 6n + 5n \cdot \lg n)$.

If `compz = 'I'` and $n > 1$ then `liwork` must be at least $(3 + 5n)$.

For `cstedc/zstedc`:

If `compz = 'N'` or `'I'`, or $n \leq 1$, `lwork` must be at least 1.

If `compz = 'V'` and $n > 1$, `lwork` must be at least n^2 .

If `compz = 'N'` or $n \leq 1$, `lrwork` must be at least 1.

If `compz = 'V'` and $n > 1$, `lrwork` must be at least $(1 + 3n + 2n \cdot \lg n + 3n^2)$, where $\lg(n)$ = smallest integer k such that $2^k \geq n$.

If `compz = 'I'` and $n > 1$, `lrwork` must be at least $(1 + 4n + 2n^2)$.

The required value of `liwork` for complex flavors is the same as for real flavors.

If `lwork` (or `liwork` or `lrwork`, if supplied) is equal to -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if `lwork` (`liwork`, `lrwork`) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?stegr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)

call dstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)

call cstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)

call zstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call rstegr(d, e, w [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])

call stegr(d, e, w [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $[vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

?sregr is a compatibility wrapper around the improved ?stemr routine. See its description for further details.

Note that the *abstol* parameter no longer provides any benefit and hence is no longer used.

See also auxiliary ?lasq2 ?lasq5, ?lasq6 , used by this routine.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu.$ If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>d</i>(*) contains the diagonal elements of T. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i>(*) contains the subdiagonal elements of T in elements 1 to $n-1$; <i>e</i>(<i>n</i>) need not be set on input, but it is used as a workspace. The dimension of <i>e</i> must be at least $\max(1, n)$. <i>work</i>(<i>lwork</i>) is a workspace array.
<i>vl, vu</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.
 Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
ldz < 1 if *jobz* = 'N';
ldz < max(1, *n*) if *jobz* = 'V', an.

lwork INTEGER.
 The dimension of the array *work*,
lwork ≥ max(1, 18**n*) if *jobz* = 'V', and
lwork ≥ max(1, 12**n*) if *jobz* = 'N'.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* below for details.

iwork INTEGER.
 Workspace array, DIMENSION (*liwork*).

liwork INTEGER.
 The dimension of the array *iwork*, *lwork* ≥ max(1, 10**n*) if the eigenvectors are desired, and *lwork* ≥ max(1, 8**n*) if only the eigenvalues are to be computed..
 If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by [xerbla](#). See *Application Notes* below for details.

Output Parameters

d, *e* On exit, *d* and *e* are overwritten.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$.
 If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu-il*+1.

w REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.

	Array, DIMENSION at least $\max(1, n)$. The selected eigenvalues in ascending order, stored in $w(1)$ to $w(m)$.
z	REAL for <code>sstegr</code> DOUBLE PRECISION for <code>dstegr</code> COMPLEX for <code>cstegr</code> DOUBLE COMPLEX for <code>zstegr</code>. Array $z(ldz, *)$, the second dimension of z must be at least $\max(1, m)$. If $jobz = 'V'$, and if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of z holding the eigenvector associated with $w(i)$. If $jobz = 'N'$, then z is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used. Supplying n columns is always safe.
$isuppz$	INTEGER. Array, DIMENSION at least $(2 * \max(1, m))$. The support of the eigenvectors in z, that is the indices indicating the nonzero elements in z. The i-th computed eigenvector is nonzero only in elements $isuppz(2*i-1)$ through $isuppz(2*i)$. This is relevant in the case when the matrix is split. $isuppz$ is only accessed when $jobz = 'V'$, and $n > 0$.
$work(1)$	On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.
$iwork(1)$	On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value. If $info = 1x$, internal error in <code>?larre</code> occurred, If $info = 2x$, internal error in <code>?larrv</code> occurred. Here the digit $x = \text{abs}(iinfo) < 10$, where $iinfo$ is the non-zero error code returned by <code>?larre</code> or <code>?larrv</code>, respectively.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stegr` interface are the following:

<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length (n) .
<code>w</code>	Holds the vector of length (n) .
<code>z</code>	Holds the matrix z of size (n, m) .
<code>isuppz</code>	Holds the vector of length $(2*m)$.
<code>vl</code>	Default value for this argument is <code>vl = - HUGE (vl)</code> where <code>HUGE(a)</code> means the largest machine number of the same precision as argument <code>a</code> .
<code>vu</code>	Default value for this argument is <code>vu = HUGE (vl)</code> .
<code>il</code>	Default value for this argument is <code>il = 1</code> .
<code>iu</code>	Default value for this argument is <code>iu = n</code> .
<code>abstol</code>	Default value for this argument is <code>abstol = 0.0_WP</code> .
<code>jobz</code>	Restored based on the presence of the argument <code>z</code> as follows: <code>jobz = 'V'</code> , if <code>z</code> is present, <code>jobz = 'N'</code> , if <code>z</code> is omitted.
<code>range</code>	Restored based on the presence of arguments <code>vl</code> , <code>vu</code> , <code>il</code> , <code>iu</code> as follows: <code>range = 'V'</code> , if one of or both <code>vl</code> and <code>vu</code> are present, <code>range = 'I'</code> , if one of or both <code>il</code> and <code>iu</code> are present, <code>range = 'A'</code> , if none of <code>vl</code> , <code>vu</code> , <code>il</code> , <code>iu</code> is present, Note that there will be an error condition if one of or both <code>vl</code> and <code>vu</code> are present and at the same time one of or both <code>il</code> and <code>iu</code> are present.

Note that two variants of Fortran 95 interface for `stegr` routine are needed because of an ambiguous choice between real and complex cases appear when `z` is omitted. Thus, the name `rstegr` is used in real cases (single or double precision), and the name `stegr` is used in complex cases (single or double precision).

Application Notes

Currently `?stegr` is only set up to find *all* the n eigenvalues and eigenvectors of T in $O(n^2)$ time, that is, only `range = 'A'` is supported.

?stegr works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution of ?stegr may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?pteqr

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call spteqr(compz, n, d, e, z, ldz, work, info)
call dpteqr(compz, n, d, e, z, ldz, work, info)
call cpteqr(compz, n, d, e, z, ldz, work, info)
call zpteqr(compz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call rpteqr(d, e [,z] [,compz] [,info])
call pteqr(d, e [,z] [,compz] [,info])
```

Description

This routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric positive-definite tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z^* \Lambda^* Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

(The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.)

You can also use the routine for computing the eigenvalues and eigenvectors of real symmetric (or complex Hermitian) positive-definite matrices A reduced to tridiagonal form T : $A = Q^* T^* Q^H$.

In this case, the spectral factorization is as follows: $A = Q^* T^* Q^H = (QZ)^* \Lambda^* (QZ)^H$. Before calling `?pteqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

	for real matrices:	for complex matrices:
full storage	<code>?sytrd, ?orgtr</code>	<code>?hetrd, ?ungtr</code>
packed storage	<code>?sptrd, ?opgtr</code>	<code>?hptrd, ?upgtr</code>
band storage	<code>?sbtrd (vect='V')</code>	<code>?hbtrd (vect='V')</code>

The routine first factorizes T as $L^* D^* L^H$ where L is a unit lower bidiagonal matrix, and D is a diagonal matrix. Then it forms the bidiagonal matrix $B = L^* D^{1/2}$ and calls `?bdsqr` to compute the singular values of B , which are the same as the eigenvalues of T .

Input Parameters

compz CHARACTER*1. Must be 'N' or 'I' or 'V'.
 If *compz* = 'N', the routine computes eigenvalues only.
 If *compz* = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T .
 If *compz* = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array z must contain the matrix Q on entry).

n	INTEGER. The order of the matrix T ($n \geq 0$).
$d, e, work$	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: $d(*)$ contains the diagonal elements of T . The dimension of d must be at least $\max(1, n)$. $e(*)$ contains the off-diagonal elements of T . The dimension of e must be at least $\max(1, n-1)$. $work(*)$ is a workspace array. The dimension of $work$ must be: at least 1 if $compz = 'N'$; at least $\max(1, 4*n-4)$ if $compz = 'V'$ or $'I'$.
z	REAL for <code>spteqr</code> DOUBLE PRECISION for <code>dpteqr</code> COMPLEX for <code>cpteqr</code> DOUBLE COMPLEX for <code>zpteqr</code> . Array, DIMENSION ($ldz, *$) If $compz = 'N'$ or $'I'$, z need not be set. If $vect = 'V'$, z must contain the n -by- n matrix Q . The second dimension of z must be: at least 1 if $compz = 'N'$; at least $\max(1, n)$ if $compz = 'V'$ or $'I'$.
ldz	INTEGER. The first dimension of z . Constraints: $ldz \geq 1$ if $compz = 'N'$; $ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

Output Parameters

d	The n eigenvalues in descending order, unless $info > 0$. See also $info$.
e	On exit, the array is overwritten.
z	If $info = 0$, contains the n orthonormal eigenvectors, stored by columns. (The i -th column corresponds to the i -th eigenvalue.)
$info$	INTEGER. If $info = 0$, the execution is successful.

If $info = i$, the leading minor of order i (and hence T itself) is not positive-definite.

If $info = n + i$, the algorithm for computing singular values failed to converge; i off-diagonal elements have not converged to zero.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pteqr` interface are the following:

d	Holds the vector of length (n) .
e	Holds the vector of length $(n-1)$.
z	Holds the matrix Z of size (n, n) .
$compz$	If omitted, this argument is restored based on the presence of argument z as follows: $compz = 'I'$, if z is present, $compz = 'N'$, if z is omitted. If present, $compz$ must be equal to 'I' or 'V' and the argument z must also be present. Note that there will be an error condition if $compz$ is present and z omitted.

Note that two variants of Fortran 95 interface for `pteqr` routine are needed because of an ambiguous choice between real and complex cases appear when z is omitted. Thus, the name `rpteqr` is used in real cases (single or double precision), and the name `pteqr` is used in complex cases (single or double precision).

Application Notes

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * K * \lambda_i$$

where $c(n)$ is a modestly increasing function of n , ϵ is the machine precision, and $K = ||DTD||_2 * ||(DTD)^{-1}||_2$, D is diagonal with $d_{ii} = t_{ii}^{-1/2}$.

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq c(n) \varepsilon_K / \min_{i \neq j} (|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|).$$

Here $\min_{i \neq j} (|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|)$ is the *relative gap* between λ_i and the other eigenvalues.

The total number of floating-point operations depends on how rapidly the algorithm converges.

Typically, it is about

$30n^2$ if `compz = 'N'`;

$6n^3$ (for complex flavors, $12n^3$) if `compz = 'V' or 'I'`.

?stebz

Computes selected eigenvalues of a real symmetric tridiagonal matrix by bisection.

Syntax

FORTRAN 77:

```
call sstebz (range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
            iblock, isplit, work, iwork, info)
```

```
call dstebz (range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
            iblock, isplit, work, iwork, info)
```

Fortran 95:

```
call stebz(d, e, m, nsplit, w, iblock, isplit [, order] [,vl] [,vu] [,il]
[,iu] [,abstol] [,info])
```

Description

This routine computes some (or all) of the eigenvalues of a real symmetric tridiagonal matrix T by bisection. The routine searches for zero or negligible off-diagonal elements to see if T splits into block-diagonal form $T = \text{diag}(T_1, T_2, \dots)$. Then it performs bisection on each of the blocks T_i and returns the block index of each computed eigenvalue, so that a subsequent call to [?stein](#) can also take advantage of the block structure.

See also [?laebz](#).

Input Parameters

<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>order</i>	CHARACTER*1. Must be 'B' or 'E'. If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block. If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>vl, vu</i>	REAL for sstebz DOUBLE PRECISION for dstebz. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. Constraint: $1 \leq il \leq iu \leq n$. If <i>range</i> = 'I', the routine computes eigenvalues $\lambda(i)$ such that $il \leq i \leq iu$ (assuming that the eigenvalues $\lambda(i)$ are in ascending order). If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for sstebz DOUBLE PRECISION for dstebz. The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width <i>abstol</i>. If <i>abstol</i> ≤ 0.0, then the tolerance is taken as $\text{eps} * T$, where <i>eps</i> is the machine precision, and T is the 1-norm of the matrix T.
<i>d, e, work</i>	REAL for sstebz

DOUBLE PRECISION for `dstebz`.

Arrays:

`d(*)` contains the diagonal elements of T .

The dimension of d must be at least $\max(1, n)$.

`e(*)` contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

`work(*)` is a workspace array.

The dimension of `work` must be at least $\max(1, 4n)$.

`iwork`

INTEGER. Workspace.

Array, DIMENSION at least $\max(1, 3n)$.

Output Parameters

`m`

INTEGER. The actual number of eigenvalues found.

`nsplit`

INTEGER. The number of diagonal blocks detected in T .

`w`

REAL for `sstebz`

DOUBLE PRECISION for `dstebz`.

Array, DIMENSION at least $\max(1, n)$. The computed eigenvalues, stored in $w(1)$ to $w(m)$.

`iblock, isplit`

INTEGER.

Arrays, DIMENSION at least $\max(1, n)$.

A positive value `iblock(i)` is the block number of the eigenvalue stored in $w(i)$ (see also `info`).

The leading `nsplit` elements of `isplit` contain points at which T splits into blocks T_i as follows: the block T_1 contains rows/columns 1 to `isplit(1)`; the block T_2 contains rows/columns `isplit(1)+1` to `isplit(2)`, and so on.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = 1`, for `range = 'A'` or `'V'`, the algorithm failed to compute some of the required eigenvalues to the desired accuracy; `iblock(i)<0` indicates that the eigenvalue stored in $w(i)$ failed to converge.

If `info = 2`, for `range = 'I'`, the algorithm failed to compute some of the required eigenvalues. Try calling the routine again with `range = 'A'`.

If `info = 3`:

for *range* = 'A' or 'V', same as *info* = 1;
 for *range* = 'I', same as *info* = 2.
 If *info* = 4, no eigenvalues have been computed. The
 floating-point arithmetic on the computer is not behaving
 as expected.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *stebz* interface are the following:

<i>d</i>	Holds the vector of length (<i>n</i>).
<i>e</i>	Holds the vector of length (<i>n</i> -1).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>iblock</i>	Holds the vector of length (<i>n</i>).
<i>isplit</i>	Holds the vector of length (<i>n</i>).
<i>order</i>	Must be 'B' or 'E'. The default value is 'B'.
<i>vl</i>	Default value for this argument is <i>vl</i> = - HUGE (<i>vl</i>) where HUGE(<i>a</i>) means the largest machine number of the same precision as argument <i>a</i> .
<i>vu</i>	Default value for this argument is <i>vu</i> = HUGE (<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this argument is <i>abstol</i> = 0.0_WP.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

The eigenvalues of T are computed to high relative accuracy which means that if they vary widely in magnitude, then any small eigenvalues will be computed more accurately than, for example, with the standard QR method. However, the reduction to tridiagonal form (prior to calling the routine) may exclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix if its eigenvalues vary widely in magnitude.

?stein

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call dstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call cstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call zstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
```

Fortran 95:

```
call stein(d, e, w, iblock, isplit, z [,ifailv] [,info])
```

Description

This routine computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. It is designed to be used in particular after the specified eigenvalues have been computed by ?stebz with `order = 'B'`, but may also be used when the eigenvalues have been computed by other routines.

If you use this routine after ?stebz, it can take advantage of the block structure by performing inverse iteration on each block T_i separately, which is more efficient than using the whole matrix T .

If T has been formed by reduction of a full symmetric or Hermitian matrix A to tridiagonal form, you can transform eigenvectors of T to eigenvectors of A by calling ?ormtr or ?opmtr (for real flavors) or by calling ?unmtr or ?upmtr (for complex flavors).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>m</i>	INTEGER. The number of eigenvectors to be returned.
<i>d</i> , <i>e</i> , <i>w</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of T . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the sub-diagonal elements of T stored in elements 1 to $n-1$. The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>w</i> (*) contains the eigenvalues of T , stored in $w(1)$ to $w(m)$ (as returned by ?stebz). Eigenvalues of T_1 must be supplied first, in non-decreasing order; then those of T_2 , again in non-decreasing order, and so on. Constraint: if $iblock(i) = iblock(i+1)$, $w(i) \leq w(i+1)$. The dimension of <i>w</i> must be at least $\max(1, n)$.
<i>iblock</i> , <i>isplit</i>	INTEGER. Arrays, DIMENSION at least $\max(1, n)$. The arrays <i>iblock</i> and <i>isplit</i> , as returned by ?stebz with <i>order</i> = 'B'. If you did not call ?stebz with <i>order</i> = 'B', set all elements of <i>iblock</i> to 1, and <i>isplit</i> (1) to <i>n</i> .)
<i>ldz</i>	INTEGER. The first dimension of the output array <i>z</i> ; $ldz \geq \max(1, n)$.
<i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Workspace array, DIMENSION at least $\max(1, 5n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>z</i>	REAL for sstein DOUBLE PRECISION for dstein COMPLEX for cstein

DOUBLE COMPLEX for `zstein`.
 Array, DIMENSION (`ldz`, *).
 If `info = 0`, `z` contains the m orthonormal eigenvectors, stored by columns. (The i th column corresponds to the i -th specified eigenvalue.)

`ifailv` INTEGER.
 Array, DIMENSION at least $\max(1, m)$.
 If `info = i > 0`, the first i elements of `ifailv` contain the indices of any eigenvectors that failed to converge.

`info` INTEGER.
 If `info = 0`, the execution is successful.
 If `info = i`, then i eigenvectors (as indicated by the parameter `ifailv`) each failed to converge in 5 iterations. The current iterates are stored in the corresponding columns of the array `z`.
 If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stein` interface are the following:

<code>d</code>	Holds the vector of length (n).
<code>e</code>	Holds the vector of length (n).
<code>w</code>	Holds the vector of length (n).
<code>iblock</code>	Holds the vector of length (n).
<code>isplit</code>	Holds the vector of length (n).
<code>z</code>	Holds the matrix Z of size (n, m).
<code>ifailv</code>	Holds the vector of length (m).

Application Notes

Each computed eigenvector z_i is an exact eigenvector of a matrix $T + E_i$, where $\|E_i\|_2 = O(\epsilon) * \|T\|_2$. However, a set of eigenvectors computed by this routine may not be orthogonal to so high a degree of accuracy as those computed by `?steqr`.

?disna

Computes the reciprocal condition numbers for the eigenvectors of a symmetric/ Hermitian matrix or for the left or right singular vectors of a general matrix.

Syntax

FORTTRAN 77:

```
call sdisna(job, m, n, d, sep, info)
call ddisna(job, m, n, d, sep, info)
```

Fortran 95:

```
call disna(d, sep [,job] [,minmn] [,info])
```

Description

This routine computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m -by- n matrix.

The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the i -th computed vector is given by

```
slamch('E')*(anorm/sep(i))
```

where $anorm = ||A||_2 = \max(|d(j)|)$. $sep(i)$ is not allowed to be smaller than $slamch('E')*anorm$ in order to limit the size of the error bound.

?disna may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'E', 'L', or 'R'. Specifies for which problem the reciprocal condition numbers should be computed: <i>job</i> = 'E': for the eigenvectors of a symmetric/Hermitian matrix; <i>job</i> = 'L': for the left singular vectors of a general matrix;

	<i>job</i> = 'R': for the right singular vectors of a general matrix.
<i>m</i>	INTEGER. The number of rows of the matrix ($m \geq 0$).
<i>n</i>	INTEGER. If <i>job</i> = 'L', or 'R', the number of columns of the matrix ($n \geq 0$). Ignored if <i>job</i> = 'E'.
<i>d</i>	REAL for sdisna DOUBLE PRECISION for ddisna. Array, dimension at least $\max(1, m)$ if <i>job</i> = 'E', and at least $\max(1, \min(m, n))$ if <i>job</i> = 'L' or 'R'. This array must contain the eigenvalues (if <i>job</i> = 'E') or singular values (if <i>job</i> = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

Output Parameters

<i>sep</i>	REAL for sdisna DOUBLE PRECISION for ddisna. Array, dimension at least $\max(1, m)$ if <i>job</i> = 'E', and at least $\max(1, \min(m, n))$ if <i>job</i> = 'L' or 'R'. The reciprocal condition numbers of the vectors.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `disna` interface are the following:

<i>d</i>	Holds the vector of length $\min(m, n)$.
<i>sep</i>	Holds the vector of length $\min(m, n)$.
<i>job</i>	Must be 'E', 'L', or 'R'. The default value is 'E'.
<i>minmn</i>	Indicates which of the values <i>m</i> or <i>n</i> is smaller. Must be either 'M' or 'N', the default is 'M'.

If $job = 'E'$, this argument is superfluous, If $job = 'L'$ or $'R'$, this argument is used by the routine.

Generalized Symmetric-Definite Eigenvalue Problems

Generalized symmetric-definite eigenvalue problems are as follows: find the eigenvalues λ and the corresponding eigenvectors z that satisfy one of these equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is an n -by- n symmetric or Hermitian matrix, and B is an n -by- n symmetric positive-definite or Hermitian positive-definite matrix.

In these problems, there exist n real eigenvectors corresponding to real eigenvalues (even for complex Hermitian matrices A and B).

Routines described in this section allow you to reduce the above generalized problems to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling LAPACK routines described earlier in this chapter (see [Symmetric Eigenvalue Problems](#)).

Different routines allow the matrices to be stored either conventionally or in packed storage. Prior to reduction, the positive-definite matrix B must first be factorized using either [?potrf](#) or [?pptrf](#).

The reduction routine for the banded matrices A and B uses a split Cholesky factorization for which a specific routine [?pbstf](#) is provided. This refinement halves the amount of work required to form matrix C .

[Table 4-4](#) lists LAPACK routines (Fortran 77 interface) that can be used to solve generalized symmetric-definite eigenvalue problems. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-4 Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Matrix type	Reduce to standard problems (full storage)	Reduce to standard problems (packed storage)	Reduce to standard problems (band matrices)	Factorize band matrix
real symmetric matrices	?sygst	?spgst	?sbgst	?pbstf
complex Hermitian matrices	?hegst	?hpgst	?hbgst	?pbstf

?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

FORTRAN 77:

```
call ssygst(itype, uplo, n, a, lda, b, ldb, info)
call dsygst(itype, uplo, n, a, lda, b, ldb, info)
```

Fortran 95:

```
call sygst(a, b [,itype] [,uplo] [,info])
```

Description

This routine reduces real symmetric-definite generalized eigenproblems

$$A^*z = \lambda^*B^*z, \quad A^*B^*z = \lambda^*z, \quad \text{or} \quad B^*A^*z = \lambda^*z$$

to the standard form $C^*y = \lambda^*y$. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call ?potrf to compute the Cholesky factorization: $B = U^T * U$ or $B = L^* L^T$.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3.
 If *itype* = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$
 for *uplo* = 'U': $C = \text{inv}(U^T) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$;
 for *uplo* = 'L': $C = \text{inv}(L) * A * \text{inv}(L^T)$, $z = \text{inv}(L^T) * y$.
 If *itype* = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^* A^* U^T$, $z = \text{inv}(U) * y$;
 for *uplo* = 'L': $C = L^T * A^* L$, $z = \text{inv}(L^T) * y$.
 If *itype* = 3, the generalized eigenproblem is $B^*A^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^* A^* U^T$, $z = U^T * y$;
 for *uplo* = 'L': $C = L^T * A^* L$, $z = L^* y$.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', the array *a* stores the upper triangle of *A*;
 you must supply *B* in the factored form $B = U^T * U$.
 If *uplo* = 'L', the array *a* stores the lower triangle of *A*;
 you must supply *B* in the factored form $B = L * L^T$.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

a, *b* REAL for ssygst
 DOUBLE PRECISION for dsygst.
 Arrays:
a(*lda*,*) contains the upper or lower triangle of *A*.
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) contains the Cholesky-factored matrix *B*:
 $B = U^T * U$ or $B = L * L^T$ (as returned by ?potrf).
 The second dimension of *b* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

Output Parameters

a The upper or lower triangle of *A* is overwritten by the upper or lower triangle of *C*, as specified by the arguments *itype* and *uplo*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sygst* interface are the following:

a Holds the matrix *A* of size (*n*,*n*).

b Holds the matrix *B* of size (*n*,*n*).

itype Must be 1, 2, or 3. The default value is 1.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $itype = 1$) or B (if $itype = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hegst

Reduces a complex Hermitian-definite generalized eigenvalue problem to the standard form.

Syntax

FORTRAN 77:

```
call chegst(itype, uplo, n, a, lda, b, ldb, info)
call zhegst(itype, uplo, n, a, lda, b, ldb, info)
```

Fortran 95:

```
call hegst(a, b [,itype] [,uplo] [,info])
```

Description

This routine reduces complex Hermitian-definite generalized eigenvalue problems

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

to the standard form $Cy = \lambda y$. Here the matrix A is complex Hermitian, and B is complex Hermitian positive-definite. Before calling this routine, you must call ?potrf to compute the Cholesky factorization: $B = U^H * U$ or $B = L * L^H$.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. If <i>itype</i> = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$ for <i>uplo</i> = 'U': $C = \text{inv}(U^H) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$; for <i>uplo</i> = 'L': $C = \text{inv}(L) * A * \text{inv}(L^H)$, $z = \text{inv}(L^H) * y$.

If $itype = 2$, the generalized eigenproblem is $A^*B^*z = \lambda z$
 for $uplo = 'U'$: $C = U^*A^*U^H$, $z = \text{inv}(U)^*y$;
 for $uplo = 'L'$: $C = L^H^*A^*L$, $z = \text{inv}(L^H)^*y$.
 If $itype = 3$, the generalized eigenproblem is $B^*A^*z = \lambda z$
 for $uplo = 'U'$: $C = U^*A^*U^H$, $z = U^H^*y$;
 for $uplo = 'L'$: $C = L^H^*A^*L$, $z = L^*y$.
 CHARACTER*1. Must be 'U' or 'L'.
 If $uplo = 'U'$, the array a stores the upper triangle of A ;
 you must supply B in the factored form $B = U^H^*U$.
 If $uplo = 'L'$, the array a stores the lower triangle of A ;
 you must supply B in the factored form $B = L^*L^H$.
 INTEGER. The order of the matrices A and B ($n \geq 0$).
 COMPLEX for chegstDOUBLE COMPLEX for zhegst.
 Arrays:
 $a(lda,*)$ contains the upper or lower triangle of A .
 The second dimension of a must be at least $\max(1, n)$.
 $b(l db,*)$ contains the Cholesky-factored matrix B :
 $B = U^H^*U$ or $B = L^*L^H$ (as returned by ?potrf).
 The second dimension of b must be at least $\max(1, n)$.
 INTEGER. The first dimension of a ; at least $\max(1, n)$.
 INTEGER. The first dimension of b ; at least $\max(1, n)$.

Output Parameters

a The upper or lower triangle of A is overwritten by the upper or lower triangle of C , as specified by the arguments $itype$ and $uplo$.
 INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegst` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix *C* is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if *itype* = 1) or *B* (if *itype* = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?spgst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

FORTRAN 77:

```
call sspgst(itype, uplo, n, ap, bp, info)
call dspgst(itype, uplo, n, ap, bp, info)
```

Fortran 95:

```
call spgst(a, b [,itype] [,uplo] [,info])
```

Description

This routine reduces real symmetric-definite generalized eigenproblems

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x$$

to the standard form $C^*Y = \lambda^*Y$, using packed matrix storage. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call `?pptrf` to compute the Cholesky factorization: $B = U^T * U$ or $B = L * L^T$.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3.
 If *itype* = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$
 for *uplo* = 'U': $C = \text{inv}(U^T) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$;
 for *uplo* = 'L': $C = \text{inv}(L) * A * \text{inv}(L^T)$, $z = \text{inv}(L^T) * y$.
 If *itype* = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^T * A * U$, $z = \text{inv}(U) * y$;
 for *uplo* = 'L': $C = L^T * A * L$, $z = \text{inv}(L^T) * y$.
 If *itype* = 3, the generalized eigenproblem is $B^*A^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^T * A * U$, $z = U^T * y$;
 for *uplo* = 'L': $C = L^T * A * L$, $z = L^T * y$.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ap* stores the packed upper triangle of A ;
 you must supply B in the factored form $B = U^T * U$.
 If *uplo* = 'L', *ap* stores the packed lower triangle of A ;
 you must supply B in the factored form $B = L * L^T$.

n INTEGER. The order of the matrices A and B ($n \geq 0$).

ap, *bp* REAL for `sspgst`
 DOUBLE PRECISION for `dspgst`.
 Arrays:
ap(*) contains the packed upper or lower triangle of A .
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.

b *p*(*) contains the packed Cholesky factor of B (as returned
 by `?pptrf` with the same *uplo* value).
 The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.

Output Parameters

<i>ap</i>	The upper or lower triangle of <i>A</i> is overwritten by the upper or lower triangle of <i>C</i> , as specified by the arguments <i>itype</i> and <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgst` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>b</i>	Stands for argument <i>bp</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(n * (n + 1) / 2)$.
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix *C* is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if *itype* = 1) or *B* (if *itype* = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hpgst

Reduces a complex Hermitian-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

FORTRAN 77:

```
call chpgst(itype, uplo, n, ap, bp, info)
call zhpgst(itype, uplo, n, ap, bp, info)
```

Fortran 95:

```
call hpgst(a, b [,itype] [,uplo] [,info])
```

Description

This routine reduces real symmetric-definite generalized eigenproblems

$A^*z = \lambda^*B^*z$, $A^*B^*z = \lambda^*z$, or $B^*A^*z = \lambda^*z$.

to the standard form $C^*y = \lambda^*y$, using packed matrix storage. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, you must call ?pptrf to compute the Cholesky factorization: $B = U^H * U$ or $B = L * L^H$.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3.
 If *itype* = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$
 for *uplo* = 'U': $C = \text{inv}(U^H) * A * \text{inv}(U)$, $z = \text{inv}(U) * y$;
 for *uplo* = 'L': $C = \text{inv}(L) * A * \text{inv}(L^H)$, $z = \text{inv}(L^H) * y$.
 If *itype* = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^*A^*U^H$, $z = \text{inv}(U) * y$;
 for *uplo* = 'L': $C = L^H * A^*L$, $z = \text{inv}(L^H) * y$.
 If *itype* = 3, the generalized eigenproblem is $B^*A^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^*A^*U^H$, $z = U^H * y$;
 for *uplo* = 'L': $C = L^H * A^*L$, $z = L * y$.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ap* stores the packed upper triangle of *A*;
 you must supply *B* in the factored form $B = U^H * U$.
 If *uplo* = 'L', *ap* stores the packed lower triangle of *A*;
 you must supply *B* in the factored form $B = L * L^H$.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ap, *bp* COMPLEX for chpgstDOUBLE COMPLEX for zhpgst.
Arrays:
ap(*) contains the packed upper or lower triangle of *A*.
 The dimension of *a* must be at least $\max(1, n*(n+1)/2)$.
bp(*) contains the packed Cholesky factor of *B* (as returned
 by *zpptrf* with the same *uplo* value).
 The dimension of *b* must be at least $\max(1, n*(n+1)/2)$.

Output Parameters

ap The upper or lower triangle of *A* is overwritten by the upper
 or lower triangle of *C*, as specified by the arguments *itype*
 and *uplo*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hpgst* interface are the following:

a Stands for argument *ap* in Fortran 77 interface. Holds the array *A* of size
 $(n*(n+1)/2)$.

b Stands for argument *bp* in Fortran 77 interface. Holds the array *B* of size
 $(n*(n+1)/2)$.

itype Must be 1, 2, or 3. The default value is 1.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $\text{itype} = 1$) or B (if $\text{itype} = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?sbgst

Reduces a real symmetric-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

FORTRAN 77:

```
call ssgbst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, info)
call dsgbst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, info)
```

Fortran 95:

```
call sbgst(a, b [,x] [,uplo] [,info])
```

Description

To reduce the real symmetric-definite generalized eigenproblem $A^*z = \lambda^*B^*z$ to the standard form $C^*y = \lambda^*y$, where A , B and C are banded, this routine must be preceded by a call to [spbstf/dpbstf](#), which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^T * S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^T * A * X$, where $X = \text{inv}(S) * Q$ and Q is an orthogonal matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , X^*z is an eigenvector of the original system.

Input Parameters

vect CHARACTER*1. Must be 'N' or 'V'.

	If <code>vect = 'N'</code>, then matrix X is not returned; If <code>vect = 'V'</code>, then matrix X is returned.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code>, ab stores the upper triangular part of A. If <code>uplo = 'L'</code>, ab stores the lower triangular part of A.
<code>n</code>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<code>ka</code>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
<code>kb</code>	INTEGER. The number of super- or sub-diagonals in B ($ka \geq kb \geq 0$).
<code>ab, bb, work</code>	REAL for <code>ssbgst</code> DOUBLE PRECISION for <code>dsbgst</code> $ab(l_{dab},*)$ is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by <code>uplo</code>) in band storage format. The second dimension of the array ab must be at least $\max(1, n)$. $bb(l_{dbb},*)$ is an array containing the banded split Cholesky factor of B as specified by <code>uplo</code>, n and <code>kb</code> and returned by spbstf/dpbstf. The second dimension of the array bb must be at least $\max(1, n)$. $work(*)$ is a workspace array, dimension at least $\max(1, 2*n)$
<code>ldab</code>	INTEGER. The first dimension of the array ab; must be at least $ka+1$.
<code>lddb</code>	INTEGER. The first dimension of the array bb; must be at least $kb+1$.
<code>ldx</code>	The first dimension of the output array x. Constraints: if <code>vect = 'N'</code>, then $ldx \geq 1$; if <code>vect = 'V'</code>, then $ldx \geq \max(1, n)$.

Output Parameters

<i>ab</i>	On exit, this array is overwritten by the upper or lower triangle of <i>C</i> as specified by <i>uplo</i> .
<i>x</i>	REAL for <i>ssbgst</i> DOUBLE PRECISION for <i>dsbgst</i> Array. If <i>vect</i> = 'V', then <i>x</i> (<i>ldx</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix $X = \text{inv}(S) * Q$. If <i>vect</i> = 'N', then <i>x</i> is not referenced. The second dimension of <i>x</i> must be: at least $\max(1, n)$, if <i>vect</i> = 'V'; at least 1, if <i>vect</i> = 'N'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sbgst* interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size (<i>ka</i> +1, <i>n</i>).
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size (<i>kb</i> +1, <i>n</i>).
<i>x</i>	Holds the matrix <i>X</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vect</i>	Restored based on the presence of the argument <i>x</i> as follows: <i>vect</i> = 'V', if <i>x</i> is present, <i>vect</i> = 'N', if <i>x</i> is omitted.

Application Notes

Forming the reduced matrix *C* involves implicit multiplication by $\text{inv}(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

If ka and kb are much less than n then the total number of floating-point operations is approximately $6n^2*kb$, when $vect = 'N'$. Additional $(3/2)n^3*(kb/ka)$ operations are required when $vect = 'V'$.

?hbgst

Reduces a complex Hermitian-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

FORTRAN 77:

```
call chbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, rwork,
info)

call zhbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, rwork,
info)
```

Fortran 95:

```
call hbgst(a, b [,x] [,uplo] [,info])
```

Description

To reduce the complex Hermitian-definite generalized eigenproblem $A^*z = \lambda^*B^*z$ to the standard form $C^*x = \lambda^*y$, where A , B and C are banded, this routine must be preceded by a call to [cpbstf/zpbstf](#), which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^H*S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^H*A*X$, where $X = \text{inv}(S)*Q$, and Q is a unitary matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , X^*z is an eigenvector of the original system.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>vect</i> = 'N', then matrix <i>x</i> is not returned; If <i>vect</i> = 'V', then matrix <i>x</i> is returned.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($ka \geq kb \geq 0$).
<i>ab, bb, work</i>	COMPLEX for <i>chbgst</i> DOUBLE COMPLEX for <i>zhbgst</i> <i>ab</i> (<i>ldab</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i>,*) is an array containing the banded split Cholesky factor of <i>B</i> as specified by <i>uplo</i>, <i>n</i> and <i>kb</i> and returned by cpbstf/zpbstf. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array, dimension at least $\max(1, n)$
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldx</i>	The first dimension of the output array <i>x</i>. Constraints: if <i>vect</i> = 'N', then $ldx \geq 1$; if <i>vect</i> = 'V', then $ldx \geq \max(1, n)$.
<i>rwork</i>	REAL for <i>chbgst</i> DOUBLE PRECISION for <i>zhbgst</i> Workspace array, dimension at least $\max(1, n)$

Output Parameters

<i>ab</i>	On exit, this array is overwritten by the upper or lower triangle of <i>C</i> as specified by <i>uplo</i> .
<i>x</i>	COMPLEX for <i>chbgst</i> DOUBLE COMPLEX for <i>zhbgst</i> Array. If <i>vect</i> = 'V', then <i>x</i> (<i>ldx</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix $X = \text{inv}(S) * Q$. If <i>vect</i> = 'N', then <i>x</i> is not referenced. The second dimension of <i>x</i> must be: at least $\max(1, n)$, if <i>vect</i> = 'V'; at least 1, if <i>vect</i> = 'N'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hbgst* interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size (<i>ka</i> +1, <i>n</i>).
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size (<i>kb</i> +1, <i>n</i>).
<i>x</i>	Holds the matrix <i>X</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vect</i>	Restored based on the presence of the argument <i>x</i> as follows: <i>vect</i> = 'V', if <i>x</i> is present, <i>vect</i> = 'N', if <i>x</i> is omitted.

Application Notes

Forming the reduced matrix *C* involves implicit multiplication by $\text{inv}(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion. The

total number of floating-point operations is approximately $20n^2*kb$, when $vect = 'N'$. Additional $5n^3*(kb/ka)$ operations are required when $vect = 'V'$. All these estimates assume that both ka and kb are much less than n .

?pbstf

Computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite banded matrix used in ?sbgst/?hbgst.

Syntax

FORTRAN 77:

```
call spbstf(uplo, n, kb, bb, ldbb, info)
call dpbstf(uplo, n, kb, bb, ldbb, info)
call cpbstf(uplo, n, kb, bb, ldbb, info)
call zpbstf(uplo, n, kb, bb, ldbb, info)
```

Fortran 95:

```
call pbstf(b [, uplo] [,info])
```

Description

This routine computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite band matrix B . It is to be used in conjunction with [?sbgst/?hbgst](#).

The factorization has the form $B = S^T * S$ (or $B = S^H * S$ for complex flavors), where S is a band matrix of the same bandwidth as B and the following structure: S is upper triangular in the first $(n+kb)/2$ rows and lower triangular in the remaining rows.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>bb</i> stores the upper triangular part of B . If <i>uplo</i> = 'L', <i>bb</i> stores the lower triangular part of B .
<i>n</i>	INTEGER. The order of the matrix B ($n \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).

bb REAL for `spbstf`
 DOUBLE PRECISION for `dpbstf`
 COMPLEX for `cpbstf`
 DOUBLE COMPLEX for `zpbstf`.
bb (*ldb*,*) is an array containing either upper or lower triangular part of the matrix *B* (as specified by *uplo*) in band storage format.
 The second dimension of the array *bb* must be at least $\max(1, n)$.

ldb INTEGER. The first dimension of *bb*; must be at least $kb+1$.

Output Parameters

bb On exit, this array is overwritten by the elements of the split Cholesky factor *S*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = *i*, then the factorization could not be completed, because the updated element b_{ii} would be the square root of a negative number; hence the matrix *B* is not positive-definite.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbstf` interface are the following:

b Stands for argument *bb* in Fortran 77 interface. Holds the array *B* of size $(kb+1, n)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed factor *S* is the exact factor of a perturbed matrix $B + E$, where

$$|E| \leq c(kb + 1)\epsilon \|S^H\| |S|, \quad |e_{ij}| \leq c(kb + 1)\epsilon \sqrt{b_{ii}b_{jj}}$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

The total number of floating-point operations for real flavors is approximately $n(kb+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that kb is much less than n .

After calling this routine, you can call `?sbgst/?hbgst` to solve the generalized eigenproblem $Az = \lambda Bz$, where A and B are banded and B is positive-definite.

Nonsymmetric Eigenvalue Problems

This section describes LAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

A *nonsymmetric eigenvalue problem* is as follows: given a nonsymmetric (or non-Hermitian) matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

Nonsymmetric eigenvalue problems have the following properties:

- The number of eigenvectors may be less than the matrix order (but is not less than the number of *distinct eigenvalues* of A).
- Eigenvalues may be complex even for a real matrix A .
- If a real nonsymmetric matrix has a complex eigenvalue $a+bi$ corresponding to an eigenvector z , then $a-bi$ is also an eigenvalue. The eigenvalue $a-bi$ corresponds to the eigenvector whose elements are complex conjugate to the elements of z .

To solve a nonsymmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained. Table 4-5 lists LAPACK routines (Fortran 77 interface) for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$ as well as routines for solving eigenvalue problems with Hessenberg matrices, forming the

Schur factorization of such matrices and computing the corresponding condition numbers. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Decision tree in [Figure 4-4](#) helps you choose the right routine or sequence of routines for an eigenvalue problem with a real nonsymmetric matrix. If you need to solve an eigenvalue problem with a complex non-Hermitian matrix, use the decision tree shown in [Figure 4-5](#).

Figure 4-4 Decision Tree: Real Nonsymmetric Eigenvalue Problems

Figure 4-5 Decision Tree: Complex Non-Hermitian Eigenvalue Problems

?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

FORTRAN 77:

```
call sgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
call dgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
call cgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
call zgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gehrd(a [, tau] [,ilo] [,ihi] [,info])
```

Description

The routine reduces a general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $A = Q^*H^*Q^H$. Here H has real subdiagonal elements.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
ilo, ihi	INTEGER. If A is an output by ?gebal, then ilo and ihi must contain the values returned by that routine. Otherwise $ilo = 1$ and $ihi = n$. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, $ilo = 1$ and $ihi = 0$.)
$a, work$	REAL for sgehrd DOUBLE PRECISION for dgehrd COMPLEX for cgehrd DOUBLE COMPLEX for zgehrd. Arrays: $a(lda,*)$ contains the matrix A. The second dimension of a must be at least $\max(1, n)$.

work (*lwork*) is a workspace array.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array; at least $\max(1, n)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by the upper Hessenberg matrix *H* and details of the matrix *Q*. The subdiagonal elements of *H* are real.

tau REAL for *sgehrd*
 DOUBLE PRECISION for *dgehrd*
 COMPLEX for *cgehrd*
 DOUBLE COMPLEX for *zgehrd*.
 Array, DIMENSION at least $\max(1, n-1)$.
 Contains additional information on the matrix *Q*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gehrd* interface are the following:

a Holds the matrix *A* of size (n, n) .

tau Holds the vector of length $(n-1)$.

ilo Default value for this argument is *ilo* = 1.

ihi Default value for this argument is *ihi* = *n*.

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Hessenberg matrix H is exactly similar to a nearby matrix $A + E$, where $\|E\|_2 < c(n)\epsilon\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is $(2/3) * (ihi - ilo)^2 (2ihi + 2ilo + 3n)$; for complex flavors it is 4 times greater.

?orghr

Generates the real orthogonal matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call sorghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
call dorghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orghr(a, tau [,ilo] [,ihi] [,info])
```

Description

This routine explicitly generates the orthogonal matrix Q that has been determined by a preceding call to `sgehrd/dgehrd`. (The routine `?gehrd` reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^* H^* Q^T$, and represents the matrix Q as a product of $ihi-ilo$ elementary reflectors. Here ilo and ihi are values determined by `sgebal/dgebal` when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

The matrix Q generated by `?orghr` has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns ilo to ihi .

Input Parameters

n	INTEGER. The order of the matrix Q ($n \geq 0$).
ilo, ihi	INTEGER. These must be the same parameters ilo and ihi , respectively, as supplied to <code>?gehrd</code> . (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, $ilo = 1$ and $ihi = 0$.)
$a, tau, work$	REAL for <code>sorghr</code> DOUBLE PRECISION for <code>dorghr</code> Arrays: $a(lda,*)$ contains details of the vectors which define the elementary reflectors, as returned by <code>?gehrd</code> . The second dimension of a must be at least $\max(1, n)$. $tau(*)$ contains further details of the elementary reflectors, as returned by <code>?gehrd</code> . The dimension of tau must be at least $\max(1, n-1)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.
$lwork$	INTEGER. The size of the $work$ array;

$lwork \geq \max(1, ihi - ilo)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*. See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>a</i>	Overwritten by the <i>n</i> -by- <i>n</i> orthogonal matrix <i>Q</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *orghr* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>tau</i>	Holds the vector of length (<i>n</i> -1).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .

Application Notes

For better performance, try using $lwork = (ihi - ilo) * blocksize$ where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix $\hat{Q}$ differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)(ihi-ilo)^3$.

The complex counterpart of this routine is [?unghr](#).

[?ormhr](#)

Multiplies an arbitrary real matrix C by the real orthogonal matrix Q determined by [?gehrd](#).

Syntax

FORTRAN 77:

```
call sormhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork,
info)
```

```
call dormhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork,
info)
```

Fortran 95:

```
call ormhr(a, tau, c [,ilo] [,ihi] [,side] [,trans] [,info])
```

Description

This routine multiplies a matrix C by the orthogonal matrix Q that has been determined by a preceding call to [sgehrd](#)/[dgehrd](#). (The routine [?gehrd](#) reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^*H^*Q^T$, and represents

the matrix Q as a product of *ihi-ilo elementary reflectors*. Here *ilo* and *ihi* are values determined by *sgebal/dgebal* when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ihi* = *n*.)

With *?ormhr*, you can form one of the matrix products Q^*C , $Q^T * C$, C^*Q , or C^*Q^T , overwriting the result on *c* (which may be any real rectangular matrix).

A common application of *?ormhr* is to transform a matrix *v* of eigenvectors of *H* to the matrix QV of eigenvectors of *A*.

Input Parameters

<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms Q^*C or $Q^T * C$. If <i>side</i> = 'R', then the routine forms C^*Q or C^*Q^T .
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T'. If <i>trans</i> = 'N', then Q is applied to <i>c</i> . If <i>trans</i> = 'T', then Q^T is applied to <i>c</i> .
<i>m</i>	INTEGER. The number of rows in <i>c</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>c</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to <i>?gehrd</i> . If $m > 0$ and <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq m$. If $m = 0$ and <i>side</i> = 'L', then <i>ilo</i> = 1 and <i>ihi</i> = 0. If $n > 0$ and <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq n$. If $n = 0$ and <i>side</i> = 'R', then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>a, tau, c, work</i>	REAL for <i>sormhr</i> DOUBLE PRECISION for <i>dormhr</i> Arrays: <i>a(lda,*)</i> contains details of the vectors which define the <i>elementary reflectors</i> , as returned by <i>?gehrd</i> . The second dimension of <i>a</i> must be at least $\max(1, m)$ if <i>side</i> = 'L' and at least $\max(1, n)$ if <i>side</i> = 'R'. <i>tau(*)</i> contains further details of the <i>elementary reflectors</i> , as returned by <i>?gehrd</i> . The dimension of <i>tau</i> must be at least $\max(1, m-1)$ if <i>side</i> = 'L' and at least $\max(1, n-1)$ if <i>side</i> = 'R'.

$c(ldc,*)$ contains the m by n matrix C . The second dimension of c must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda INTEGER. The first dimension of a ; at least $\max(1, m)$ if $side = 'L'$ and at least $\max(1, n)$ if $side = 'R'$.
ldc INTEGER. The first dimension of c ; at least $\max(1, m)$.
lwork INTEGER. The size of the $work$ array.
 If $side = 'L'$, $lwork \geq \max(1, n)$.
 If $side = 'R'$, $lwork \geq \max(1, m)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c C is overwritten by product Q^*C , $Q^T C$, C^*Q , or $C^T Q$ as specified by $side$ and $trans$.
 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormhr` interface are the following:

a Holds the matrix A of size (r, r) .
 $r = m$ if $side = 'L'$.
 $r = n$ if $side = 'R'$.
 τ Holds the vector of length $(r-1)$.

<i>c</i>	Holds the matrix <i>c</i> of size (m,n) .
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, *lwork* should be at least $n \times \text{blocksize}$ if *side* = 'L' and at least $m \times \text{blocksize}$ if *side* = 'R', where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from the exact result by a matrix *E* such that $\|E\|_2 = O(\epsilon) \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$2n(ihi-ilo)^2$ if *side* = 'L';

$2m(ihi-ilo)^2$ if *side* = 'R'.

The complex counterpart of this routine is [?unmhr](#).

?unghr

Generates the complex unitary matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call cunghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
call zunghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call unghr(a, tau [,ilo] [,ihi] [,info])
```

Description

This routine is intended to be used following a call to cgehrd/zgehrd, which reduces a complex matrix A to upper Hessenberg form H by a unitary similarity transformation: $A = Q^* H Q$.

?gehrd represents the matrix Q as a product of $ihi-ilo$ *elementary reflectors*. Here ilo and ihi are values determined by cgebal/zgebal when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.

Use the routine ?unghr to generate Q explicitly as a square matrix. The matrix Q has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns ilo to ihi .

Input Parameters

n INTEGER. The order of the matrix Q ($n \geq 0$).

<i>ilo, ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to <code>?gehrd</code> . (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n = 0$, then $ilo = 1$ and $ihi = 0$.)
<i>a, tau, work</i>	COMPLEX for <code>cunghr</code> DOUBLE COMPLEX for <code>zunghr</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains details of the vectors which define the <i>elementary reflectors</i> , as returned by <code>?gehrd</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>tau</i> (*) contains further details of the <i>elementary reflectors</i> , as returned by <code>?gehrd</code> . The dimension of <i>tau</i> must be at least $\max(1, n-1)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq \max(1, ihi-ilo)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the n -by- n unitary matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unghr` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>tau</code>	Holds the vector of length $(n-1)$.
<code>ilo</code>	Default value for this argument is $ilo = 1$.
<code>ihi</code>	Default value for this argument is $ihi = n$.

Application Notes

For better performance, try using $lwork = (ihi-ilo)*blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of real floating-point operations is $(16/3)(ihi-ilo)^3$.

The real counterpart of this routine is `?orghr`.

?unmhr

Multiplies an arbitrary complex matrix C by the complex unitary matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call cunmhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork,
info)

call zunmhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork,
info)
```

Fortran 95:

```
call unmhr(a, tau, c [,ilo] [,ihi] [,side] [,trans] [,info])
```

Description

This routine multiplies a matrix C by the unitary matrix Q that has been determined by a preceding call to cgehrd/zgehrd. (The routine ?gehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^H H Q$, and represents the matrix Q as a product of $ihi-ilo$ elementary reflectors. Here ilo and ihi are values determined by cgebal/zgebal when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

With ?unmhr, you can form one of the matrix products $Q^H C$, $Q^H C Q$, $C Q$, or $C Q^H$, overwriting the result on C (which may be any complex rectangular matrix). A common application of this routine is to transform a matrix V of eigenvectors of H to the matrix QV of eigenvectors of A .

Input Parameters

<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms $Q^H C$ or $Q^H C Q$. If <i>side</i> = 'R', then the routine forms $C Q$ or $C Q^H$.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'C'. If <i>trans</i> = 'N', then Q is applied to C . If <i>trans</i> = 'T', then Q^H is applied to C .
<i>m</i>	INTEGER. The number of rows in C ($m \geq 0$).

n INTEGER. The number of columns in *c* ($n \geq 0$).

ilo, ihi INTEGER. These must be the same parameters *ilo* and *ihi*, respectively, as supplied to `?gehrd`.

If $m > 0$ and *side* = 'L', then $1 \leq ilo \leq ihi \leq m$.
 If $m = 0$ and *side* = 'L', then *ilo* = 1 and *ihi* = 0.
 If $n > 0$ and *side* = 'R', then $1 \leq ilo \leq ihi \leq n$.
 If $n = 0$ and *side* = 'R', then *ilo* = 1 and *ihi* = 0.

a, tau, c, work COMPLEX for `cunmhr`
 DOUBLE COMPLEX for `zunmhr`.
 Arrays:
a(*lda*,*) contains details of the vectors which define the elementary reflectors, as returned by `?gehrd`.
 The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L' and at least $\max(1, n)$ if *side* = 'R'.
tau(*) contains further details of the elementary reflectors, as returned by `?gehrd`.
 The dimension of *tau* must be at least $\max(1, m-1)$ if *side* = 'L' and at least $\max(1, n-1)$ if *side* = 'R'.
c(*ldc*,*) contains the *m*-by-*n* matrix *C*. The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$ if *side* = 'L' and at least $\max(1, n)$ if *side* = 'R'.

ldc INTEGER. The first dimension of *c*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array.
 If *side* = 'L', $lwork \geq \max(1, n)$.
 If *side* = 'R', $lwork \geq \max(1, m)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	<i>c</i> is overwritten by $Q^H C$, or $Q^H C$, or $C^H Q$, or $C^H Q$ as specified by <i>side</i> and <i>trans</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmhr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>r</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>r</i> -1).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, *lwork* should be at least $n \times \text{blocksize}$ if *side* = 'L' and at least $m \times \text{blocksize}$ if *side* = 'R', where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$8n(ihi-ilo)^2$ if `side = 'L'`;

$8m(ihi-ilo)^2$ if `side = 'R'`.

The real counterpart of this routine is [?ormhr](#).

[?gebal](#)

Balances a general matrix to improve the accuracy of computed eigenvalues and eigenvectors.

Syntax

FORTRAN 77:

```
call sgebal(job, n, a, lda, ilo, ihi, scale, info)
call dgebal(job, n, a, lda, ilo, ihi, scale, info)
call cgebal(job, n, a, lda, ilo, ihi, scale, info)
call zgebal(job, n, a, lda, ilo, ihi, scale, info)
```

Fortran 95:

```
call gebal(a [, scale] [,ilo] [,ihi] [,job] [,info])
```

Description

This routine *balances* a matrix *A* by performing either or both of the following two similarity transformations:

- (1) The routine first attempts to permute *A* to block upper triangular form:

$$PAP^T = A' = \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix}$$

where *P* is a permutation matrix, and *A'*₁₁ and *A'*₃₃ are upper triangular. The diagonal elements of *A'*₁₁ and *A'*₃₃ are eigenvalues of *A*. The rest of the eigenvalues of *A* are the eigenvalues of the central diagonal block *A'*₂₂, in rows and columns *ilo* to *ihi*. Subsequent operations to compute the eigenvalues of *A* (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if *ilo* > 1 and *ihi* < *n*.

If no suitable permutation exists (as is often the case), the routine sets *ilo* = 1 and *ihi* = *n*, and *A'*₂₂ is the whole of *A*.

- (2) The routine applies a diagonal similarity transformation to *A'*, to make the rows and columns of *A'*₂₂ as close in norm as possible:

$$A'' = DA'D^{-1} = \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{bmatrix} \times \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix} \times \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22}^{-1} & 0 \\ 0 & 0 & I \end{bmatrix}$$

This scaling can reduce the norm of the matrix (that is, $\|A'_{22}\| < \|A'_{22}\|$), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

Input Parameters

job CHARACTER*1. Must be 'N' or 'P' or 'S' or 'B'.

If $job = 'N'$, then A is neither permuted nor scaled (but ilo , ihi , and $scale$ get their values).
 If $job = 'P'$, then A is permuted but not scaled.
 If $job = 'S'$, then A is scaled but not permuted.
 If $job = 'B'$, then A is both scaled and permuted.

n INTEGER. The order of the matrix A ($n \geq 0$).

a REAL for sgebal
 DOUBLE PRECISION for dgebal
 COMPLEX for cgebal
 DOUBLE COMPLEX for zgebal.
 Arrays:
 $a(lda,*)$ contains the matrix A .
 The second dimension of a must be at least $\max(1, n)$. a is not referenced if $job = 'N'$.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

Output Parameters

a Overwritten by the balanced matrix (a is not referenced if $job = 'N'$).

ilo, ihi INTEGER. The values ilo and ihi such that on exit $a(i, j)$ is zero if $i > j$ and $1 \leq j < ilo$ or $ihi < i \leq n$.
 If $job = 'N'$ or $'S'$, then $ilo = 1$ and $ihi = n$.

$scale$ REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors
 Array, DIMENSION at least $\max(1, n)$.
 Contains details of the permutations and scaling factors.
 More precisely, if p_j is the index of the row and column interchanged with row and column j , and d_j is the scaling factor used to balance row and column j , then
 $scale(j) = p_j$ for $j = 1, 2, \dots, ilo-1, ihi+1, \dots, n$;
 $scale(j) = d_j$ for $j = ilo, ilo + 1, \dots, ihi$.
 The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

$info$ INTEGER.

If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebal` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>scale</i>	Holds the vector of length (<i>n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

Application Notes

The errors are negligible, compared with those in subsequent computations.

If the matrix *A* is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix *A*'', and hence you must call `?gebak` to transform them back to eigenvectors of *A*.

If the Schur vectors of *A* are required, do not call this routine with *job* = 'S' or 'B', because then the balancing transformation is not orthogonal (not unitary for complex flavors).

If you call this routine with *job* = 'P', then any Schur vectors computed subsequently are Schur vectors of the matrix *A*'', and you need to call `?gebak` (with *side* = 'R') to transform them back to Schur vectors of *A*.

The total number of floating-point operations is proportional to n^2 .

?gebak

Transforms eigenvectors of a balanced matrix to those of the original nonsymmetric matrix.

Syntax

FORTRAN 77:

```
call sgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call dgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call cgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call zgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
```

Fortran 95:

```
call gebak(v, scale [,ilo] [,ihi] [,job] [,side] [,info])
```

Description

This routine is intended to be used after a matrix A has been balanced by a call to ?gebal, and eigenvectors of the balanced matrix A''_{22} have subsequently been computed. For a description of balancing, see ?gebal. The balanced matrix A'' is obtained as $A'' = D * P * A * P^T * \text{inv}(D)$, where P is a permutation matrix and D is a diagonal scaling matrix. This routine transforms the eigenvectors as follows:

if x is a right eigenvector of A'' , then $P^T * \text{inv}(D) * x$ is a right eigenvector of A ; if x is a left eigenvector of A'' , then $P^T * D * y$ is a left eigenvector of A .

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'N' or 'P' or 'S' or 'B'. The same parameter <i>job</i> as supplied to ?gebal.
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then left eigenvectors are transformed. If <i>side</i> = 'R', then right eigenvectors are transformed.
<i>n</i>	INTEGER. The number of rows of the matrix of eigenvectors ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. The values <i>ilo</i> and <i>ihi</i> , as returned by ?gebal. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;

	if $n = 0$, then $ilo = 1$ and $ihi = 0$.)
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors Array, DIMENSION at least $\max(1, n)$. Contains details of the permutations and/or the scaling factors used to balance the original general matrix, as returned by ?gebal.
<i>m</i>	INTEGER. The number of columns of the matrix of eigenvectors ($m \geq 0$).
<i>v</i>	REAL for sgebak DOUBLE PRECISION for dgebak COMPLEX for cgebak DOUBLE COMPLEX for zgebak. Arrays: $v(ldv,*)$ contains the matrix of left or right eigenvectors to be transformed. The second dimension of v must be at least $\max(1, m)$.
<i>ldv</i>	INTEGER. The first dimension of v ; at least $\max(1, n)$.

Output Parameters

<i>v</i>	Overwritten by the transformed eigenvectors.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebak` interface are the following:

<i>v</i>	Holds the matrix v of size (n, m) .
<i>scale</i>	Holds the vector of length (n) .
<i>ilo</i>	Default value for this argument is $ilo = 1$.
<i>ihi</i>	Default value for this argument is $ihi = n$.

job Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.
side Must be 'L' or 'R'. The default value is 'L'.

Application Notes

The errors in this routine are negligible.

The approximate number of floating-point operations is approximately proportional to $m \cdot n$.

?hseqr

Computes all eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

FORTRAN 77:

```
call shseqr(job, compz, n, ilo, ihi, h, ldh, wr, wi, z, ldz, work, lwork,
info)

call dhseqr(job, compz, n, ilo, ihi, h, ldh, wr, wi, z, ldz, work, lwork,
info)

call chseqr(job, compz, n, ilo, ihi, h, ldh, w, z, ldz, work, lwork, info)
call zhseqr(job, compz, n, ilo, ihi, h, ldh, w, z, ldz, work, lwork, info)
```

Fortran 95:

```
call hseqr(h, wr, wi [,ilo] [,ihi] [,z] [,job] [,compz] [,info])
call hseqr(h, w [,ilo] [,ihi] [,z] [,job] [,compz] [,info])
```

Description

This routine computes all the eigenvalues, and optionally the Schur factorization, of an upper Hessenberg matrix H : $H = Z^* T^* Z^H$, where T is an upper triangular (or, for real flavors, quasi-triangular) matrix (the Schur form of H), and Z is the unitary or orthogonal matrix whose columns are the Schur vectors z_i .

You can also use this routine to compute the Schur factorization of a general matrix A which has been reduced to upper Hessenberg form H :

$A = Q^* H^* Q^H$, where Q is unitary (orthogonal for real flavors);

$$A = (QZ)^* H^* (QZ)^H.$$

In this case, after reducing A to Hessenberg form by `?gehrd`, call `?orghr` to form Q explicitly and then pass Q to `?hseqr` with `compz = 'V'`.

You can also call `?gebal` to balance the original matrix before reducing it to Hessenberg form by `?hseqr`, so that the Hessenberg matrix H will have the structure:

$$\begin{bmatrix} H_{11} & H_{12} & H_{13} \\ 0 & H_{22} & H_{23} \\ 0 & 0 & H_{33} \end{bmatrix}$$

where H_{11} and H_{33} are upper triangular.

If so, only the central diagonal block H_{22} (in rows and columns ilo to ihi) needs to be further reduced to Schur form (the blocks H_{12} and H_{23} are also affected). Therefore the values of ilo and ihi can be supplied to `?hseqr` directly. Also, after calling this routine you must call `?gebak` to permute the Schur vectors of the balanced matrix to those of the original matrix.

If `?gebal` has not been called, however, then ilo must be set to 1 and ihi to n . Note that if the Schur factorization of A is required, `?gebal` must not be called with `job = 'S'` or `'B'`, because the balancing transformation is not unitary (for real flavors, it is not orthogonal).

`?hseqr` uses a multishift form of the upper Hessenberg QR algorithm. The Schur vectors are normalized so that $\|z_i\|_2 = 1$, but are determined only to within a complex factor of absolute value 1 (for the real flavors, to within a factor ± 1).

Input Parameters

<code>job</code>	CHARACTER*1. Must be 'E' or 'S'. If <code>job = 'E'</code>, then eigenvalues only are required. If <code>job = 'S'</code>, then the Schur form T is required.
<code>compz</code>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <code>compz = 'N'</code>, then no Schur vectors are computed (and the array z is not referenced). If <code>compz = 'I'</code>, then the Schur vectors of H are computed (and the array z is initialized by the routine).

If *compz* = 'V', then the Schur vectors of *A* are computed (and the array *z* must contain the matrix *Q* on entry).

n INTEGER. The order of the matrix *H* ($n \geq 0$).

ilo, ihi INTEGER. If *A* has been balanced by ?gebal, then *ilo* and *ihi* must contain the values returned by ?gebal. Otherwise, *ilo* must be set to 1 and *ihi* to *n*.

h, z, work REAL for shseqr
DOUBLE PRECISION for dhseqr
COMPLEX for chseqr
DOUBLE COMPLEX for zhseqr.

Arrays:
h(ldh,)* The *n*-by-*n* upper Hessenberg matrix *H*.
 The second dimension of *h* must be at least $\max(1, n)$.
z(ldz,)*
 If *compz* = 'V', then *z* must contain the matrix *Q* from the reduction to Hessenberg form.
 If *compz* = 'I', then *z* need not be set.
 If *compz* = 'N', then *z* is not referenced.
 The second dimension of *z* must be
 at least $\max(1, n)$ if *compz* = 'V' or 'I';
 at least 1 if *compz* = 'N'.
work(lwork) is a workspace array.
 The dimension of *work* must be at least $\max(1, n)$.

ldh INTEGER. The first dimension of *h*; at least $\max(1, n)$.

ldz INTEGER. The first dimension of *z*;
 If *compz* = 'N', then $ldz \geq 1$.
 If *compz* = 'V' or 'I', then $ldz \geq \max(1, n)$.

lwork INTEGER. The dimension of the array *work*.
 $lwork \geq \max(1, n)$ is sufficient, but *lwork* typically as large as $6*n$ may be required for optimal performance. A workspace query to determine the optimal workspace size is recommended.

If `lwork = -1`, then a workspace query is assumed; the routine only estimates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<code>w</code>	COMPLEX for <code>chseqr</code> DOUBLE COMPLEX for <code>zhseqr</code>. Array, DIMENSION at least $\max(1, n)$. Contains the computed eigenvalues, unless <code>info</code>>0. The eigenvalues are stored in the same order as on the diagonal of the Schur form T (if computed).
<code>wr, wi</code>	REAL for <code>shseqr</code> DOUBLE PRECISION for <code>dhseqr</code> Arrays, DIMENSION at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, unless <code>info</code> > 0. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. The eigenvalues are stored in the same order as on the diagonal of the Schur form T (if computed).
<code>h</code>	If <code>info</code> = 0 and <code>job</code> = 'S', <code>h</code> contains the upper triangular matrix T from the Schur decomposition (the Schur form). If <code>info</code> = 0 and <code>job</code> = 'E', the contents of <code>h</code> are unspecified on exit. (The output value of <code>h</code> when <code>info</code> > 0 is given under the description of <code>info</code> below.)
<code>z</code>	If <code>compz</code> = 'V' and <code>info</code> = 0, then <code>z</code> contains Q^*Z. If <code>compz</code> = 'I' and <code>info</code> = 0, then <code>z</code> contains the unitary or orthogonal matrix Z of the Schur vectors of H. If <code>compz</code> = 'N', then <code>z</code> is not referenced.
<code>work(1)</code>	On exit, if <code>info</code> = 0, then <code>work(1)</code> returns the optimal <code>lwork</code>.
<code>info</code>	INTEGER. If <code>info</code> = 0, the execution is successful. If <code>info</code> = $-i$, the i-th parameter had an illegal value.

If $info = i$, elements $1, 2, \dots, ilo-1$ and $i+1, i+2, \dots, n$ of wr and wi contain the real and imaginary parts of those eigenvalues that have been successively found.

If $info > 0$, and $job = 'E'$, then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns ilo through $info$ of the final output value of H .

If $info > 0$, and $job = 'S'$, then on exit (initial value of H)* $U = U$ *(final value of H), where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns $info+1$ through ihi .

If $info > 0$, and $compz = 'V'$, then on exit (final value of Z) = (initial value of Z)* U , where U is the unitary matrix (regardless of the value of job).

If $info > 0$, and $compz = 'I'$, then on exit (final value of Z) = U , where U is the unitary matrix (regardless of the value of job).

If $info > 0$, and $compz = 'N'$, then Z is not accessed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hseqr` interface are the following:

<code>h</code>	Holds the matrix H of size (n, n) .
<code>wr</code>	Holds the vector of length (n) . Used in real flavors only.
<code>wi</code>	Holds the vector of length (n) . Used in real flavors only.
<code>w</code>	Holds the vector of length (n) . Used in complex flavors only.
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>job</code>	Must be <code>'E'</code> or <code>'S'</code> . The default value is <code>'E'</code> .
<code>compz</code>	If omitted, this argument is restored based on the presence of argument z as follows: <code>compz = 'I'</code> , if z is present, <code>compz = 'N'</code> , if z is omitted. If present, <code>compz</code> must be equal to <code>'I'</code> or <code>'V'</code> and the argument z must also be present. Note that there will be an error condition if <code>compz</code> is present and z omitted.

Application Notes

The computed Schur factorization is the exact factorization of a nearby matrix $H + E$, where $\|E\|_2 < O(\epsilon) \|H\|_2 / s_i$, and ϵ is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then $|\lambda_i - \mu_i| \leq c(n) \epsilon \|H\|_2 / s_i$, where $c(n)$ is a modestly increasing function of n , and s_i is the reciprocal condition number of λ_i . The condition numbers s_i may be computed by calling [?trsna](#).

The total number of floating-point operations depends on how rapidly the algorithm converges; typical numbers are as follows.

If only eigenvalues are computed: $7n^3$ for real flavors
 $25n^3$ for complex flavors.

If the Schur form is computed: $10n^3$ for real flavors
 $35n^3$ for complex flavors.

If the full Schur factorization is computed: $20n^3$ for real flavors
 $70n^3$ for complex flavors.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hsein

Computes selected eigenvectors of an upper Hessenberg matrix that correspond to specified eigenvalues.

Syntax

FORTRAN 77:

```
call shsein(job, eigsrc, initv, select, n, h, ldh, wr, wi, vl, ldvl, vr, ldvr,
mm, m, work, ifaill, ifailr, info)

call dhsein(job, eigsrc, initv, select, n, h, ldh, wr, wi, vl, ldvl, vr, ldvr,
mm, m, work, ifaill, ifailr, info)

call chsein(job, eigsrc, initv, select, n, h, ldh, w, vl, ldvl, vr, ldvr, mm,
m, work, rwork, ifaill, ifailr, info)

call zhsein(job, eigsrc, initv, select, n, h, ldh, w, vl, ldvl, vr, ldvr, mm,
m, work, rwork, ifaill, ifailr, info)
```

Fortran 95:

```
call hsein(h, wr, wi, select [, vl] [,vr] [,ifaill] [,ifailr] [,initv]
[,eigsrc] [,m] [,info])

call hsein(h, w, select [,vl] [,vr] [,ifaill] [,ifailr] [,initv] [,eigsrc]
[,m] [,info])
```

Description

This routine computes left and/or right eigenvectors of an upper Hessenberg matrix H , corresponding to selected eigenvalues.

The right eigenvector x and the left eigenvector y , corresponding to an eigenvalue λ , are defined by: $H^*x = \lambda^*x$ and $y^H H = \lambda^* y^H$ (or $H^H y = \lambda^* y$). Here λ^* denotes the conjugate of λ .

The eigenvectors are computed by inverse iteration. They are scaled so that, for a real eigenvector x , $\max |x_i| = 1$, and for a complex eigenvector, $\max (|\operatorname{Re} x_i| + |\operatorname{Im} x_i|) = 1$.

If H has been formed by reduction of a general matrix A to upper Hessenberg form, then eigenvectors of H may be transformed to eigenvectors of A by [?ormhr](#) or [?unmhr](#).

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'R' or 'L' or 'B'. If <i>job</i> = 'R', then only right eigenvectors are computed. If <i>job</i> = 'L', then only left eigenvectors are computed. If <i>job</i> = 'B', then all eigenvectors are computed.
<i>eigsrc</i>	CHARACTER*1. Must be 'Q' or 'N'. If <i>eigsrc</i> = 'Q', then the eigenvalues of <i>H</i> were found using ?hseqr; thus if <i>H</i> has any zero sub-diagonal elements (and so is block triangular), then the <i>j</i>-th eigenvalue can be assumed to be an eigenvalue of the block containing the <i>j</i>-th row/column. This property allows the routine to perform inverse iteration on just one diagonal block. If <i>eigsrc</i> = 'N', then no such assumption is made and the routine performs inverse iteration using the whole matrix.
<i>initv</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>initv</i> = 'N', then no initial estimates for the selected eigenvectors are supplied. If <i>initv</i> = 'U', then initial estimates for the selected eigenvectors are supplied in <i>vl</i> and/or <i>vr</i>.
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, <i>n</i>). Specifies which eigenvectors are to be computed. <i>For real flavors:</i> To obtain the real eigenvector corresponding to the real eigenvalue <i>wr(j)</i>, set <i>select(j)</i> to .TRUE. To select the complex eigenvector corresponding to the complex eigenvalue (<i>wr(j)</i>, <i>wi(j)</i>) with complex conjugate (<i>wr(j+1)</i>, <i>wi(j+1)</i>), set <i>select(j)</i> and/or <i>select(j+1)</i> to .TRUE.; the eigenvector corresponding to the first eigenvalue in the pair is computed. <i>For complex flavors:</i> To select the eigenvector corresponding to the eigenvalue <i>w(j)</i>, set <i>select(j)</i> to .TRUE.
<i>n</i>	INTEGER. The order of the matrix <i>H</i> (<i>n</i> ≥ 0).
<i>h</i> , <i>vl</i> , <i>vr</i> ,	REAL for shsein DOUBLE PRECISION for dhsein

COMPLEX for chsein
DOUBLE COMPLEX for zhsein.

Arrays:
 $h(ldh,*)$ The n -by- n upper Hessenberg matrix H .
The second dimension of h must be at least $\max(1, n)$.
 $(ldvl,*)$
If $initv = 'V'$ and $job = 'L'$ or $'B'$, then vl must contain starting vectors for inverse iteration for the left eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.
If $initv = 'N'$, then vl need not be set.
The second dimension of vl must be at least $\max(1, mm)$ if $job = 'L'$ or $'B'$ and at least 1 if $job = 'R'$.
The array vl is not referenced if $job = 'R'$.
 $vr(ldvr,*)$
If $initv = 'V'$ and $job = 'R'$ or $'B'$, then vr must contain starting vectors for inverse iteration for the right eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.
If $initv = 'N'$, then vr need not be set.
The second dimension of vr must be at least $\max(1, mm)$ if $job = 'R'$ or $'B'$ and at least 1 if $job = 'L'$.
The array vr is not referenced if $job = 'L'$.
 $work(*)$ is a workspace array.
DIMENSION at least $\max(1, n*(n+2))$ for real flavors and at least $\max(1, n*n)$ for complex flavors.

ldh INTEGER. The first dimension of h ; at least $\max(1, n)$.

w COMPLEX for chsein
DOUBLE COMPLEX for zhsein.
Array, DIMENSION at least $\max(1, n)$.
Contains the eigenvalues of the matrix H .
If $eigsrc = 'Q'$, the array must be exactly as returned by ?hseqr.

wr, wi REAL for shsein
DOUBLE PRECISION for dhsein
Arrays, DIMENSION at least $\max(1, n)$ each.

	Contain the real and imaginary parts, respectively, of the eigenvalues of the matrix H . Complex conjugate pairs of values must be stored in consecutive elements of the arrays. If $eigsrc = 'Q'$, the arrays must be exactly as returned by ?hseqr.
<i>ldvl</i>	INTEGER. The first dimension of vl . If $job = 'L'$ or $'B'$, $ldvl \geq \max(1, n)$. If $job = 'R'$, $ldvl \geq 1$.
<i>ldvr</i>	INTEGER. The first dimension of vr . If $job = 'R'$ or $'B'$, $ldvr \geq \max(1, n)$. If $job = 'L'$, $ldvr \geq 1$.
<i>mm</i>	INTEGER. The number of columns in vl and/or vr . Must be at least m , the actual number of columns required (see <i>Output Parameters</i> below). For real flavors, m is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector (see <i>select</i>). For complex flavors, m is the number of selected eigenvectors (see <i>select</i>). Constraint: $0 \leq mm \leq n$.
<i>rwork</i>	REAL for chsein DOUBLE PRECISION for zhsein. Array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>select</i>	Overwritten for real flavors only. If a complex eigenvector was selected as specified above, then $select(j)$ is set to <code>.TRUE.</code> and $select(j+1)$ to <code>.FALSE.</code>
<i>w</i>	The real parts of some elements of w may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

<i>wr</i>	Some elements of <i>wr</i> may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.
<i>vl, vr</i>	If <i>job</i> = 'L' or 'B', <i>vl</i> contains the computed left eigenvectors (as specified by <i>select</i>). If <i>job</i> = 'R' or 'B', <i>vr</i> contains the computed right eigenvectors (as specified by <i>select</i>). The eigenvectors are stored consecutively in the columns of the array, in the same order as their eigenvalues. <i>For real flavors</i>: a real eigenvector corresponding to a selected real eigenvalue occupies one column; a complex eigenvector corresponding to a selected complex eigenvalue occupies two columns: the first column holds the real part and the second column holds the imaginary part.
<i>m</i>	INTEGER. <i>For real flavors</i>: the number of columns of <i>vl</i> and/or <i>vr</i> required to store the selected eigenvectors. <i>For complex flavors</i>: the number of selected eigenvectors.
<i>ifaill, ifailr</i>	INTEGER. Arrays, DIMENSION at least $\max(1, mm)$ each. <i>ifaill</i>(<i>i</i>) = 0 if the <i>i</i>th column of <i>vl</i> converged; <i>ifaill</i>(<i>i</i>) = <i>j</i> > 0 if the eigenvector stored in the <i>i</i>-th column of <i>vl</i> (corresponding to the <i>j</i>th eigenvalue) failed to converge. <i>ifailr</i>(<i>i</i>) = 0 if the <i>i</i>th column of <i>vr</i> converged; <i>ifailr</i>(<i>i</i>) = <i>j</i> > 0 if the eigenvector stored in the <i>i</i>-th column of <i>vr</i> (corresponding to the <i>j</i>th eigenvalue) failed to converge. <i>For real flavors</i>: if the <i>i</i>th and (<i>i</i>+1)th columns of <i>vl</i> contain a selected complex eigenvector, then <i>ifaill</i>(<i>i</i>) and <i>ifaill</i>(<i>i</i>+1) are set to the same value. A similar rule holds for <i>vr</i> and <i>ifailr</i>. The array <i>ifaill</i> is not referenced if <i>job</i> = 'R'. The array <i>ifailr</i> is not referenced if <i>job</i> = 'L'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

If $info > 0$, then i eigenvectors (as indicated by the parameters *ifaill* and/or *ifailr* above) failed to converge. The corresponding columns of *vl* and/or *vr* contain no useful information.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hsein` interface are the following:

<i>h</i>	Holds the matrix H of size (n, n) .
<i>wr</i>	Holds the vector of length (n) . Used in real flavors only.
<i>wi</i>	Holds the vector of length (n) . Used in real flavors only.
<i>w</i>	Holds the vector of length (n) . Used in complex flavors only.
<i>select</i>	Holds the vector of length (n) .
<i>vl</i>	Holds the matrix VL of size (n, mm) .
<i>vr</i>	Holds the matrix VR of size (n, mm) .
<i>ifaill</i>	Holds the vector of length (mm) . Note that there will be an error condition if <i>ifaill</i> is present and <i>vl</i> is omitted.
<i>ifailr</i>	Holds the vector of length (mm) . Note that there will be an error condition if <i>ifailr</i> is present and <i>vr</i> is omitted.
<i>initv</i>	Must be 'N' or 'U'. The default value is 'N'.
<i>eigsrc</i>	Must be 'N' or 'Q'. The default value is 'N'.
<i>job</i>	Restored based on the presence of arguments <i>vl</i> and <i>vr</i> as follows: $job = 'B'$, if both <i>vl</i> and <i>vr</i> are present, $job = 'L'$, if <i>vl</i> is present and <i>vr</i> omitted, $job = 'R'$, if <i>vl</i> is omitted and <i>vr</i> present, Note that there will be an error condition if both <i>vl</i> and <i>vr</i> are omitted.

Application Notes

Each computed right eigenvector x_i is the exact eigenvector of a nearby matrix $A + E_i$, such that $\|E_i\| < O(\epsilon) \|A\|$. Hence the residual is small:

$$\|Ax_i - \lambda_i x_i\| = O(\epsilon) \|A\|.$$

However, eigenvectors corresponding to close or coincident eigenvalues may not accurately span the relevant subspaces.

Similar remarks apply to computed left eigenvectors.

?trevc

Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by ?hseqr.

Syntax

FORTRAN 77:

```
call strevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work,
info)

call dtrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work,
info)

call ctrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work,
rwork, info)

call ztrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work,
rwork, info)
```

Fortran 95:

```
call trevc(t [, howmny] [,select] [,vl] [,vr] [,m] [,info])
```

Description

This routine computes some or all of the right and/or left eigenvectors of an upper triangular matrix T (or, for real flavors, an upper quasi-triangular matrix T). Matrices of this type are produced by the Schur factorization of a general matrix: $A = Q^* T^* Q^H$, as computed by ?hseqr.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w , are defined by:

$$T^* x = w^* x, \quad y^H T = w^* y^H, \quad \text{where } y^H \text{ denotes the conjugate transpose of } y.$$

The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T .

This routine returns the matrices X and/or Y of right and left eigenvectors of T , or the products $Q^* X$ and/or $Q^* Y$, where Q is an input matrix.

If Q is the orthogonal/unitary factor that reduces a matrix A to Schur form T , then Q^*X and Q^*Y are the matrices of right and left eigenvectors of A .

Input Parameters

<i>side</i>	CHARACTER*1. Must be 'R' or 'L' or 'B'. If <i>side</i> = 'R' , then only right eigenvectors are computed. If <i>side</i> = 'L' , then only left eigenvectors are computed. If <i>side</i> = 'B' , then all eigenvectors are computed.
<i>howmny</i>	CHARACTER*1. Must be 'A' or 'B' or 'S'. If <i>howmny</i> = 'A' , then all eigenvectors (as specified by <i>side</i>) are computed. If <i>howmny</i> = 'B' , then all eigenvectors (as specified by <i>side</i>) are computed and backtransformed by the matrices supplied in <i>vl</i> and <i>vr</i>. If <i>howmny</i> = 'S' , then selected eigenvectors (as specified by <i>side</i> and <i>select</i>) are computed.
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, <i>n</i>). If <i>howmny</i> = 'S' , <i>select</i> specifies which eigenvectors are to be computed. If <i>howmny</i> = 'A' or 'B' , <i>select</i> is not referenced. For real flavors: If <i>omega</i>(<i>j</i>) is a real eigenvalue, the corresponding real eigenvector is computed if <i>select</i>(<i>j</i>) is .TRUE.. If <i>omega</i>(<i>j</i>) and <i>omega</i>(<i>j</i>+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either <i>select</i>(<i>j</i>) or <i>select</i>(<i>j</i>+1) is .TRUE., and on exit <i>select</i>(<i>j</i>) is set to .TRUE. and <i>select</i>(<i>j</i>+1) is set to .FALSE.. For complex flavors: The eigenvector corresponding to the <i>j</i>-th eigenvalue is computed if <i>select</i>(<i>j</i>) is .TRUE..
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>t</i> , <i>vl</i> , <i>vr</i> ,	REAL for <i>strevc</i> DOUBLE PRECISION for <i>dtrevc</i> COMPLEX for <i>ctrevc</i> DOUBLE COMPLEX for <i>ztrevc</i>.

Arrays:

$t(ldt,*)$ contains the n -by- n matrix T in Schur canonical form.

The second dimension of t must be at least $\max(1, n)$.

$vl(ldvl,*)$

If $howmny = 'B'$ and $side = 'L'$ or $'B'$, then vl must contain an n -by- n matrix Q (usually the matrix of Schur vectors returned by `?hseqr`).

If $howmny = 'A'$ or $'S'$, then vl need not be set.

The second dimension of vl must be at least $\max(1, mm)$ if $side = 'L'$ or $'B'$ and at least 1 if $side = 'R'$.

The array vl is not referenced if $side = 'R'$.

$vr(ldvr,*)$

If $howmny = 'B'$ and $side = 'R'$ or $'B'$, then vr must contain an n -by- n matrix Q (usually the matrix of Schur vectors returned by `?hseqr`). .

If $howmny = 'A'$ or $'S'$, then vr need not be set.

The second dimension of vr must be at least $\max(1, mm)$ if $side = 'R'$ or $'B'$ and at least 1 if $side = 'L'$.

The array vr is not referenced if $side = 'L'$.

$work(*)$ is a workspace array.

DIMENSION at least $\max(1, 3*n)$ for real flavors and at least $\max(1, 2*n)$ for complex flavors.

ldt INTEGER. The first dimension of t ; at least $\max(1, n)$.

$ldvl$ INTEGER. The first dimension of vl .

If $side = 'L'$ or $'B'$, $ldvl \geq n$.

If $side = 'R'$, $ldvl \geq 1$.

$ldvr$ INTEGER. The first dimension of vr .

If $side = 'R'$ or $'B'$, $ldvr \geq n$.

If $side = 'L'$, $ldvr \geq 1$.

mm INTEGER. The number of columns in the arrays vl and/or vr . Must be at least m (the precise number of columns required).

If $howmny = 'A'$ or $'B'$, $m = n$.

If *howmny* = 'S': for real flavors, *m* is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector;
for complex flavors, *m* is the number of selected eigenvectors (see *select*).

Constraint: $0 \leq m \leq n$.

rwork

REAL for ctrevc
DOUBLE PRECISION for ztrevc.
Workspace array, DIMENSION at least max (1, *n*).

Output Parameters

select

If a complex eigenvector of a real matrix was selected as specified above, then *select*(*j*) is set to .TRUE. and *select*(*j*+1) to .FALSE.

vl, *vr*

If *side* = 'L' or 'B', *vl* contains the computed left eigenvectors (as specified by *howmny* and *select*).
If *side* = 'R' or 'B', *vr* contains the computed right eigenvectors (as specified by *howmny* and *select*).
The eigenvectors are stored consecutively in the columns of the array, in the same order as their eigenvalues.
For real flavors: corresponding to each real eigenvalue is a real eigenvector, occupying one column; corresponding to each complex conjugate pair of eigenvalues is a complex eigenvector, occupying two columns; the first column holds the real part and the second column holds the imaginary part.

m

INTEGER.
For complex flavors: the number of selected eigenvectors.
If *howmny* = 'A' or 'B', *m* is set to *n*.
For real flavors: the number of columns of *vl* and/or *vr* actually used to store the selected eigenvectors.
If *howmny* = 'A' or 'B', *m* is set to *n*.

info

INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trevc` interface are the following:

<code>t</code>	Holds the matrix T of size (n, n) .
<code>select</code>	Holds the vector of length (n) .
<code>vl</code>	Holds the matrix VL of size (n, mm) .
<code>vr</code>	Holds the matrix VR of size (n, mm) .
<code>side</code>	If omitted, this argument is restored based on the presence of arguments <code>vl</code> and <code>vr</code> as follows: <code>side = 'B'</code>, if both <code>vl</code> and <code>vr</code> are present, <code>side = 'L'</code>, if <code>vr</code> is omitted, <code>side = 'R'</code>, if <code>vl</code> is omitted. Note that there will be an error condition if both <code>vl</code> and <code>vr</code> are omitted.
<code>howmny</code>	If omitted, this argument is restored based on the presence of argument <code>select</code> as follows: <code>howmny = 'V'</code>, if <code>q</code> is present, <code>howmny = 'N'</code>, if <code>q</code> is omitted. If present, <code>vect = 'V'</code> or <code>'U'</code> and the argument <code>q</code> must also be present. Note that there will be an error condition if both <code>select</code> and <code>howmny</code> are present.

Application Notes

If x_i is an exact right eigenvector and y_i is the corresponding computed eigenvector, then the angle $\theta(y_i, x_i)$ between them is bounded as follows: $\theta(y_i, x_i) \leq (c(n)\epsilon \|T\|_2) / \text{sep}_i$ where sep_i is the reciprocal condition number of x_i . The condition number sep_i may be computed by calling `?trsna`.

?trsna

Estimates condition numbers for specified eigenvalues and right eigenvectors of an upper (quasi-) triangular matrix.

Syntax

FORTRAN 77:

```
call strsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm,
m, work, ldwork, iwork, info)

call dtrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm,
m, work, ldwork, iwork, info)

call ctrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm,
m, work, ldwork, rwork, info)

call ztrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm,
m, work, ldwork, rwork, info)
```

Fortran 95:

```
call trsna(t [, s] [,sep] [,vl] [,vr] [,select] [,m] [,info])
```

Description

This routine estimates condition numbers for specified eigenvalues and/or right eigenvectors of an upper triangular matrix T (or, for real flavors, upper quasi-triangular matrix T in canonical Schur form). These are the same as the condition numbers of the eigenvalues and right eigenvectors of an original matrix $A = Z^* T^* Z^H$ (with unitary or, for real flavors, orthogonal Z), from which T may have been derived.

The routine computes the reciprocal of the condition number of an eigenvalue $\lambda(i)$ as $s_i = |v_H^* u| / (||u||_E ||v||_E)$, where u and v are the right and left eigenvectors of T , respectively, corresponding to $\lambda(i)$. This reciprocal condition number always lies between zero (ill-conditioned) and one (well-conditioned).

An approximate error estimate for a computed eigenvalue $\lambda(i)$ is then given by $\epsilon * ||T|| / s_i$, where ϵ is the *machine precision*.

To estimate the reciprocal of the condition number of the right eigenvector corresponding to $\lambda(i)$, the routine first calls [?trexc](#) to reorder the eigenvalues so that $\lambda(i)$ is in the leading position:

$$T = Q \begin{bmatrix} \lambda_i & C^H \\ 0 & T_{22} \end{bmatrix} Q^H$$

The reciprocal condition number of the eigenvector is then estimated as sep_i , the smallest singular value of the matrix $T_{22} - \lambda_i I$. This number ranges from zero (ill-conditioned) to very large (well-conditioned).

An approximate error estimate for a computed right eigenvector u corresponding to λ_i is then given by $\epsilon^* ||T|| / sep_i$.

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'E' or 'V' or 'B'. If <i>job</i> = 'E', then condition numbers for eigenvalues only are computed. If <i>job</i> = 'V', then condition numbers for eigenvectors only are computed. If <i>job</i> = 'B', then condition numbers for both eigenvalues and eigenvectors are computed.
<i>howmny</i>	CHARACTER*1. Must be 'A' or 'S'. If <i>howmny</i> = 'A', then the condition numbers for all eigenpairs are computed. If <i>howmny</i> = 'S', then condition numbers for selected eigenpairs (as specified by <i>select</i>) are computed.
<i>select</i>	LOGICAL. Array, DIMENSION at least $\max(1, n)$ if <i>howmny</i> = 'S' and at least 1 otherwise. Specifies the eigenpairs for which condition numbers are to be computed if <i>howmny</i> = 'S'. <i>For real flavors:</i> To select condition numbers for the eigenpair corresponding to the real eigenvalue $\lambda(j)$, <i>select</i>(<i>j</i>) must be set .TRUE.;

to select condition numbers for the eigenpair corresponding to a complex conjugate pair of eigenvalues $\lambda(j)$ and $\lambda(j+1)$, $\text{select}(j)$ and/or $\text{select}(j+1)$ must be set `.TRUE.`

For complex flavors

To select condition numbers for the eigenpair corresponding to the eigenvalue $\lambda(j)$, $\text{select}(j)$ must be set `.TRUE.`
 select is not referenced if $\text{howmny} = 'A'$.

n

INTEGER. The order of the matrix T ($n \geq 0$).

$t, vl, vr, work$

REAL for `strsna`

DOUBLE PRECISION for `dtrsna`

COMPLEX for `ctrsna`

DOUBLE COMPLEX for `ztrsna`.

Arrays:

$t(ldt,*)$ contains the n -by- n matrix T .

The second dimension of t must be at least $\max(1, n)$.

$vl(ldvl,*)$

If $\text{job} = 'E'$ or $'B'$, then vl must contain the left eigenvectors of T (or of any matrix $Q^*T^*Q^H$ with Q unitary or orthogonal) corresponding to the eigenpairs specified by howmny and select . The eigenvectors must be stored in consecutive columns of vl , as returned by [?trevc](#) or [?hsein](#).

The second dimension of vl must be at least $\max(1, mm)$ if $\text{job} = 'E'$ or $'B'$ and at least 1 if $\text{job} = 'V'$.

The array vl is not referenced if $\text{job} = 'V'$.

$vr(ldvr,*)$

If $\text{job} = 'E'$ or $'B'$, then vr must contain the right eigenvectors of T (or of any matrix $Q^*T^*Q^H$ with Q unitary or orthogonal) corresponding to the eigenpairs specified by howmny and select . The eigenvectors must be stored in consecutive columns of vr , as returned by [?trevc](#) or [?hsein](#).

The second dimension of vr must be at least $\max(1, mm)$ if $\text{job} = 'E'$ or $'B'$ and at least 1 if $\text{job} = 'V'$.

The array vr is not referenced if $\text{job} = 'V'$.

$work$ is a workspace array, its dimension $(ldwork, n+6)$.

	The array <i>work</i> is not referenced if <i>job</i> = 'E'.
<i>ldt</i>	INTEGER. The first dimension of <i>t</i> ; at least $\max(1, n)$.
<i>ldvl</i>	INTEGER. The first dimension of <i>vl</i> . If <i>job</i> = 'E' or 'B', $ldvl \geq \max(1, n)$. If <i>job</i> = 'V', $ldvl \geq 1$.
<i>ldvr</i>	INTEGER. The first dimension of <i>vr</i> . If <i>job</i> = 'E' or 'B', $ldvr \geq \max(1, n)$. If <i>job</i> = 'R', $ldvr \geq 1$.
<i>mm</i>	INTEGER. The number of elements in the arrays <i>s</i> and <i>sep</i> , and the number of columns in <i>vl</i> and <i>vr</i> (if used). Must be at least <i>m</i> (the precise number required). If <i>howmny</i> = 'A', $m = n$; if <i>howmny</i> = 'S', for real flavors <i>m</i> is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues. for complex flavors <i>m</i> is the number of selected eigenpairs (see <i>select</i>). Constraint: $0 \leq m \leq n$.
<i>ldwork</i>	INTEGER. The first dimension of <i>work</i> . If <i>job</i> = 'V' or 'B', $ldwork \geq \max(1, n)$. If <i>job</i> = 'E', $ldwork \geq 1$.
<i>rwork</i>	REAL for <i>ctrсна</i> , <i>ztrsna</i> . Array, DIMENSION at least $\max(1, n)$.
<i>iwork</i>	INTEGER for <i>strсна</i> , <i>dtrsna</i> . Array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>s</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, mm)$ if <i>job</i> = 'E' or 'B' and at least 1 if <i>job</i> = 'V'. Contains the reciprocal condition numbers of the selected eigenvalues if <i>job</i> = 'E' or 'B', stored in consecutive elements of the array. Thus <i>s</i> (<i>j</i>), <i>sep</i> (<i>j</i>) and the <i>j</i> -th

columns of vl and vr all correspond to the same eigenpair (but not in general the j th eigenpair unless all eigenpairs have been selected).

For real flavors: for a complex conjugate pair of eigenvalues, two consecutive elements of S are set to the same value. The array s is not referenced if $job = 'V'$.

sep

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, mm)$ if $job = 'V'$ or $'B'$ and at least 1 if $job = 'E'$. Contains the estimated reciprocal condition numbers of the selected right eigenvectors if $job = 'V'$ or $'B'$, stored in consecutive elements of the array.

For real flavors: for a complex eigenvector, two consecutive elements of sep are set to the same value; if the eigenvalues cannot be reordered to compute $sep(j)$, then $sep(j)$ is set to zero; this can only occur when the true value would be very small anyway. The array sep is not referenced if $job = 'E'$.

m

INTEGER.

For complex flavors: the number of selected eigenpairs.

If $howmny = 'A'$, m is set to n .

For real flavors: the number of elements of s and/or sep actually used to store the estimated condition numbers.

If $howmny = 'A'$, m is set to n .

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsna` interface are the following:

t	Holds the matrix T of size (n, n) .
s	Holds the vector of length (mm) .

<i>sep</i>	Holds the vector of length (<i>mm</i>).
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>mm</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>mm</i>).
<i>select</i>	Holds the vector of length (<i>n</i>).
<i>job</i>	Restored based on the presence of arguments <i>s</i> and <i>sep</i> as follows: <i>job</i> = 'B', if both <i>s</i> and <i>sep</i> are present, <i>job</i> = 'E', if <i>s</i> is present and <i>sep</i> omitted, <i>job</i> = 'V', if <i>s</i> is omitted and <i>sep</i> present. Note an error condition if both <i>s</i> and <i>sep</i> are omitted.
<i>howmny</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>howmny</i> = 'S', if <i>select</i> is present, <i>howmny</i> = 'A', if <i>select</i> is omitted.

Note that the arguments *s*, *vl*, and *vr* must either be all present or all omitted.

Otherwise, an error condition is observed.

Application Notes

The computed values sep_i may overestimate the true value, but seldom by a factor of more than 3.

?trexc

Reorders the Schur factorization of a general matrix.

Syntax

FORTRAN 77:

```
call strexc(compq, n, t, ldt, q, ldq, ifst, ilst, work, info)
call dtrexc(compq, n, t, ldt, q, ldq, ifst, ilst, work, info)
call ctrexc(compq, n, t, ldt, q, ldq, ifst, ilst, info)
call ztrexc(compq, n, t, ldt, q, ldq, ifst, ilst, info)
```

Fortran 95:

```
call trexc(t, ifst, ilst [,q] [,info])
```

Description

This routine reorders the Schur factorization of a general matrix $A = Q^*T^*Q^H$, so that the diagonal element or block of T with row index *ifst* is moved to row *ilst*.

The reordered Schur form S is computed by an unitary (or, for real flavors, orthogonal) similarity transformation: $S = Z^H * T * Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q * Z$, giving $A = P * S * P^H$.

Input Parameters

<i>compq</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>compq</i> = 'V', then the Schur vectors (Q) are updated. If <i>compq</i> = 'N', then no Schur vectors are updated.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>t, q</i>	REAL for strexc DOUBLE PRECISION for dtrexc COMPLEX for ctrexc DOUBLE COMPLEX for ztrexc. Arrays: <i>t</i> (<i>ldt</i> ,*) contains the n -by- n matrix T . The second dimension of <i>t</i> must be at least max(1, n). <i>q</i> (<i>ldq</i> ,*) If <i>compq</i> = 'V', then <i>q</i> must contain Q (Schur vectors). If <i>compq</i> = 'N', then <i>q</i> is not referenced. The second dimension of <i>q</i> must be at least max(1, n) if <i>compq</i> = 'V' and at least 1 if <i>compq</i> = 'N'.
<i>ldt</i>	INTEGER. The first dimension of <i>t</i> ; at least max(1, n).
<i>ldq</i>	INTEGER. The first dimension of <i>q</i> ; If <i>compq</i> = 'N', then <i>ldq</i> $\geq$ 1. If <i>compq</i> = 'V', then <i>ldq</i> $\geq$ max(1, n).
<i>ifst, ilst</i>	INTEGER. $1 \leq ifst \leq n$; $1 \leq ilst \leq n$. Must specify the reordering of the diagonal elements (or blocks, which is possible for real flavors) of the matrix T . The element (or block) with row index <i>ifst</i> is moved to row <i>ilst</i> by a sequence of exchanges between adjacent elements (or blocks).

work REAL for `strexc`
 DOUBLE PRECISION for `dtrexc`.
 Array, DIMENSION at least $\max(1, n)$.

Output Parameters

t Overwritten by the updated matrix S .

q If `compq` = 'V', q contains the updated matrix of Schur vectors.

ifst, ilst Overwritten for real flavors only.
 If *ifst* pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; *ilst* always points to the first row of the block in its final position (which may differ from its input value by ± 1).

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trexc` interface are the following:

t Holds the matrix T of size (n, n) .

q Holds the matrix Q of size (n, n) .

compq Restored based on the presence of the argument q as follows:
`compq` = 'V', if q is present,
`compq` = 'N', if q is omitted.

Application Notes

The computed matrix S is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) * \|T\|_2$, and ϵ is the machine precision.

Note that if a 2 by 2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2 by 2 block to break into two 1 by 1 blocks, that is, for a pair of complex eigenvalues to become purely real.

The values of eigenvalues however are never changed by the re-ordering.

The approximate number of floating-point operations is

for real flavors:	$6n(ifst-ilst)$ if <code>compq = 'N'</code> ;
	$12n(ifst-ilst)$ if <code>compq = 'V'</code> ;
for complex flavors:	$20n(ifst-ilst)$ if <code>compq = 'N'</code> ;
	$40n(ifst-ilst)$ if <code>compq = 'V'</code> .

?trsen

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

FORTRAN 77:

```
call strsen(job, compq, select, n, t, ldt, q, ldq, wr, wi, m, s, sep, work,
lwork, iwork, liwork, info)

call dtrsen(job, compq, select, n, t, ldt, q, ldq, wr, wi, m, s, sep, work,
lwork, iwork, liwork, info)

call ctrsen(job, compq, select, n, t, ldt, q, ldq, w, m, s, sep, work, lwork,
info)

call ztrsen(job, compq, select, n, t, ldt, q, ldq, w, m, s, sep, work, lwork,
info)
```

Fortran 95:

```
call trsen(t, select [,wr] [,wi] [,m] [,s] [,sep] [,q] [,info])

call trsen(t, select [,w] [,m] [,s] [,sep] [,q] [,info])
```

Description

This routine reorders the Schur factorization of a general matrix $A = Q^* T^* Q^H$ so that a selected cluster of eigenvalues appears in the leading diagonal elements (or, for real flavors, diagonal blocks) of the Schur form. The reordered Schur form R is computed by an unitary (orthogonal) similarity transformation: $R = Z^H * T^* Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q^* Z$, giving $A = P^* R^* P^H$.

Let

$$R = \begin{bmatrix} T_{11} & T_{12} \\ \mathbf{0} & T_{13} \end{bmatrix}$$

where the selected eigenvalues are precisely the eigenvalues of the leading m -by- m submatrix T_{11} . Let P be correspondingly partitioned as $(Q_1 \ Q_2)$ where Q_1 consists of the first m columns of Q . Then $A^* Q_1 = Q_1^* T_{11}$, and so the m columns of Q_1 form an orthonormal basis for the invariant subspace corresponding to the selected cluster of eigenvalues.

Optionally the routine also computes estimates of the reciprocal condition numbers of the average of the cluster of eigenvalues and of the invariant subspace.

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'N' or 'E' or 'V' or 'B'. If <i>job</i> = 'N', then no condition numbers are required. If <i>job</i> = 'E', then only the condition number for the cluster of eigenvalues is computed. If <i>job</i> = 'V', then only the condition number for the invariant subspace is computed. If <i>job</i> = 'B', then condition numbers for both the cluster and the invariant subspace are computed.
<i>compq</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>compq</i> = 'V', then Q of the Schur vectors is updated. If <i>compq</i> = 'N', then no Schur vectors are updated.
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, n).

Specifies the eigenvalues in the selected cluster. To select an eigenvalue $\lambda(j)$, $\text{select}(j)$ must be `.TRUE.`.

For real flavors: to select a complex conjugate pair of eigenvalues $\lambda(j)$ and $\lambda(j+1)$ (corresponding 2 by 2 diagonal block), $\text{select}(j)$ and/or $\text{select}(j+1)$ must be `.TRUE.`; the complex conjugate $\lambda(j)$ and $\lambda(j+1)$ must be either both included in the cluster or both excluded.

n

INTEGER. The order of the matrix T ($n \geq 0$).

$t, q, work$

REAL for strsen

DOUBLE PRECISION for dtrsen

COMPLEX for ctrsen

DOUBLE COMPLEX for ztrsen.

Arrays:

$t(ldt,*)$ The n -by- n T .

The second dimension of t must be at least $\max(1, n)$.

$q(ldq,*)$

If $compq = 'V'$, then q must contain q of Schur vectors.

If $compq = 'N'$, then q is not referenced.

The second dimension of q must be at least $\max(1, n)$ if

$compq = 'V'$ and at least 1 if $compq = 'N'$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

ldt

INTEGER. The first dimension of t ; at least $\max(1, n)$.

ldq

INTEGER. The first dimension of q ;

If $compq = 'N'$, then $ldq \geq 1$.

If $compq = 'V'$, then $ldq \geq \max(1, n)$.

$lwork$

INTEGER. The dimension of the array $work$.

If $job = 'V'$ or $'B'$, $lwork \geq \max(1, 2*m*(n-m))$.

If $job = 'E'$, then $lwork \geq \max(1, m*(n-m))$

If $job = 'N'$, then $lwork \geq 1$ for complex flavors and

$lwork \geq \max(1, n)$ for real flavors.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`. See *Application Notes* for details.

`iwork`

INTEGER.`iwork`(`liwork`) is a workspace array. The array `iwork` is not referenced if `job = 'N'` or `'E'`.

The actual amount of workspace required cannot exceed $n^2/2$ if `job = 'V'` or `'B'`.

`liwork`

INTEGER.

The dimension of the array `iwork`.

If `job = 'V'` or `'B'`, $liwork \geq \max(1, 2m(n-m))$.

If `job = 'E'` or `'E'`, $liwork \geq 1$.

If `liwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `iwork` array, returns this value as the first entry of the `iwork` array, and no error message related to `liwork` is issued by `xerbla`. See *Application Notes* for details.

Output Parameters

`t`

Overwritten by the updated matrix R .

`q`

If `compq = 'V'`, `q` contains the updated matrix of Schur vectors; the first m columns of the `q` form an orthogonal basis for the specified invariant subspace.

`w`

COMPLEX for `ctrsen`

DOUBLE COMPLEX for `ztrsen`.

Array, DIMENSION at least $\max(1, n)$. The recorded eigenvalues of R . The eigenvalues are stored in the same order as on the diagonal of R .

`wr, wi`

REAL for `strsen`

DOUBLE PRECISION for `dtrsen`

Arrays, DIMENSION at least $\max(1, n)$. Contain the real and imaginary parts, respectively, of the reordered eigenvalues of R . The eigenvalues are stored in the same order as on

the diagonal of R . Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

m

INTEGER.

For complex flavors: the number of the specified invariant subspaces, which is the same as the number of selected eigenvalues (see *select*).

For real flavors: the dimension of the specified invariant subspace. The value of m is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues (see *select*).

Constraint: $0 \leq m \leq n$.

s

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

If $job = 'E'$ or $'B'$, s is a lower bound on the reciprocal condition number of the average of the selected cluster of eigenvalues.

If $m = 0$ or n , then $s = 1$.

For real flavors: if $info = 1$, then s is set to zero. s is not referenced if $job = 'N'$ or $'V'$.

sep

REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

If $job = 'V'$ or $'B'$, sep is the estimated reciprocal condition number of the specified invariant subspace.

If $m = 0$ or n , then $sep = |T|$.

For real flavors: if $info = 1$, then sep is set to zero.

sep is not referenced if $job = 'N'$ or $'E'$.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the optimal size of $lwork$.

$iwork(1)$

On exit, if $info = 0$, then $iwork(1)$ returns the optimal size of $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsen` interface are the following:

<code>t</code>	Holds the matrix T of size (n, n) .
<code>select</code>	Holds the vector of length (n) .
<code>wr</code>	Holds the vector of length (n) . Used in real flavors only.
<code>wi</code>	Holds the vector of length (n) . Used in real flavors only.
<code>w</code>	Holds the vector of length (n) . Used in complex flavors only.
<code>q</code>	Holds the matrix Q of size (n, n) .
<code>compq</code>	Restored based on the presence of the argument <code>q</code> as follows: <code>compq</code> = 'V', if <code>q</code> is present, <code>compq</code> = 'N', if <code>q</code> is omitted.
<code>job</code>	Restored based on the presence of arguments <code>s</code> and <code>sep</code> as follows: <code>job</code> = 'B', if both <code>s</code> and <code>sep</code> are present, <code>job</code> = 'E', if <code>s</code> is present and <code>sep</code> omitted, <code>job</code> = 'V', if <code>s</code> is omitted and <code>sep</code> present, <code>job</code> = 'N', if both <code>s</code> and <code>sep</code> are omitted.

Application Notes

The computed matrix R is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) \|T\|_2$, and ϵ is the machine precision. The computed s cannot underestimate the true reciprocal condition number by more than a factor of $(\min(m, n-m))_{1/2}$; `sep` may differ from the true value by $(m^*n-m^2)_{1/2}$. The angle between the computed invariant subspace and the true subspace is $O(\epsilon) \|A\|_2 / \text{sep}$. Note that if a 2-by-2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2-by-2 block to break into two 1-by-1 blocks, that is, for a pair of complex eigenvalues to become purely real. The values of eigenvalues however are never changed by the re-ordering.

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork` = -1 (`liwork` = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?trsyl

Solves Sylvester equation for real quasi-triangular or complex triangular matrices.

Syntax

FORTRAN 77:

```
call strsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call dtrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call ctrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call ztrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
```

Fortran 95:

```
call trsyl(a, b, c, scale [, trana] [,tranb] [,isgn] [,info])
```

Description

This routine solves the Sylvester matrix equation $\text{op}(A) * X \pm X * \text{op}(B) = \alpha * C$, where $\text{op}(A) = A$ or A^H , and the matrices A and B are upper triangular (or, for real flavors, upper quasi-triangular in canonical Schur form); $\alpha \leq 1$ is a scale factor determined by the routine to avoid overflow in X ; A is m -by- m , B is n -by- n , and C and X are both m -by- n . The matrix X is obtained by a straightforward process of back substitution.

The equation has a unique solution if and only if $\alpha_i \pm \beta_i \neq 0$, where $\{\alpha_i\}$ and $\{\beta_i\}$ are the eigenvalues of A and B , respectively, and the sign (+ or -) is the same as that used in the equation to be solved.

Input Parameters

<i>trana</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If <i>trana</i> = 'N', then $\text{op}(A) = A$. If <i>trana</i> = 'T', then $\text{op}(A) = A^T$ (real flavors only). If <i>trana</i> = 'C' then $\text{op}(A) = A^H$.
<i>tranb</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If <i>tranb</i> = 'N', then $\text{op}(B) = B$. If <i>tranb</i> = 'T', then $\text{op}(B) = B^T$ (real flavors only). If <i>tranb</i> = 'C', then $\text{op}(B) = B^H$.
<i>isgn</i>	INTEGER. Indicates the form of the Sylvester equation. If <i>isgn</i> = +1, $\text{op}(A)*X + X*\text{op}(B) = \alpha*C$. If <i>isgn</i> = -1, $\text{op}(A)*X - X*\text{op}(B) = \alpha*C$.
<i>m</i>	INTEGER. The order of A , and the number of rows in X and C ($m \geq 0$).
<i>n</i>	INTEGER. The order of B , and the number of columns in X and C ($n \geq 0$).
<i>a, b, c</i>	REAL for <i>strsyl</i> DOUBLE PRECISION for <i>dtrsyl</i> COMPLEX for <i>ctrsyl</i> DOUBLE COMPLEX for <i>ztrsyl</i> . Arrays: <i>a(lda,*)</i> contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, m)$. <i>b(l db,*)</i> contains the matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>c(l dc,*)</i> contains the matrix C . The second dimension of <i>c</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; at least $\max(1, n)$.

Output Parameters

<i>c</i>	Overwritten by the solution matrix <i>X</i> .
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. The value of the scale factor α .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, <i>A</i> and <i>B</i> have common or close eigenvalues perturbed values were used to solve the equation.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsyl` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>m</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>trana</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>tranb</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>isgn</i>	Must be +1 or -1. The default value is +1.

Application Notes

Let *X* be the exact, *Y* the corresponding computed solution, and *R* the residual matrix: $R = C - (AY \pm YB)$. Then the residual is always small:

$$\|R\|_F = O(\epsilon) * (\|A\|_F + \|B\|_F) * \|Y\|_F.$$

However, *Y* is not necessarily the exact solution of a slightly perturbed equation; in other words, the solution is not backwards stable.

For the forward error, the following bound holds:

$$\|Y - X\|_F \leq \|R\|_F / \text{sep}(A, B)$$

but this may be a considerable overestimate. See [Golub96] for a definition of $\text{sep}(A, B)$.
The approximate number of floating-point operations for real flavors is $m^*n^*(m + n)$. For complex flavors it is 4 times greater.

Generalized Nonsymmetric Eigenvalue Problems

This section describes LAPACK routines for solving generalized nonsymmetric eigenvalue problems, reordering the generalized Schur factorization of a pair of matrices, as well as performing a number of related computational tasks.

A *generalized nonsymmetric eigenvalue problem* is as follows: given a pair of nonsymmetric (or non-Hermitian) n -by- n matrices A and B , find the *generalized eigenvalues* λ and the corresponding *generalized eigenvectors* x and y that satisfy the equations

$Ax = \lambda Bx$ (right generalized eigenvectors x)

and

$y^H A = \lambda y^H B$ (left generalized eigenvectors y).

Table 4-6 lists LAPACK routines (Fortran 77 interface) used to solve the generalized nonsymmetric eigenvalue problems and the generalized Sylvester equation. Respective routine names in Fortran 95 interface are without the first symbol (see Routine Naming Conventions).

Table 4-6 Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems

Routine name	Operation performed
?gghrd	Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.
?ggbal	Balances a pair of general real or complex matrices.
?ggbak	Forms the right or left eigenvectors of a generalized eigenvalue problem.
?hgeqz	Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T) .
?tgevc	Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices
?tgexc	Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.

Routine name	Operation performed
?tgsgen	Reorders the <i>generalized</i> Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B).
?tgssyl	Solves the generalized Sylvester equation.
?tgssna	Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

[?ggghrd](#)

Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.

Syntax

FORTRAN 77:

```
call sgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call dgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call cgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call zgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
```

Fortran 95:

```
call ggghrd(a, b [,ilo] [,ihi] [,q] [,z] [,compq] [,compz] [,info])
```

Description

This routine reduces a pair of real/complex matrices (A, B) to generalized upper Hessenberg form using orthogonal/unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is $A^*x = \lambda^*B^*x$, and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This routine simultaneously reduces A to a Hessenberg matrix H :

$$Q^H A Z = H$$

and transforms B to another upper triangular matrix T :

$$Q^H * B * Z = T$$

in order to reduce the problem to its standard form $H^*Y = \lambda^*T^*Y$, where $Y = Z^H * X$.

The orthogonal/unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q_1 and Z_1 , so that

$$Q_1^* A^* Z_1^H = (Q_1^* Q)^* H^* (Z_1^* Z)^H$$

$$Q_1^* B^* Z_1^H = (Q_1^* Q)^* T^* (Z_1^* Z)^H$$

If Q_1 is the orthogonal/unitary matrix from the QR factorization of B in the original equation $A^*X = \lambda^*B^*X$, then the routine `?gghrd` reduces the original problem to generalized Hessenberg form.

Input Parameters

compq CHARACTER*1. Must be 'N', 'I', or 'V'.
 If *compq* = 'N', matrix Q is not computed.
 If *compq* = 'I', Q is initialized to the unit matrix, and the orthogonal/unitary matrix Q is returned;
 If *compq* = 'V', Q must contain an orthogonal/unitary matrix Q_1 on entry, and the product Q_1^*Q is returned.

compz CHARACTER*1. Must be 'N', 'I', or 'V'.
 If *compz* = 'N', matrix Z is not computed.
 If *compz* = 'I', Z is initialized to the unit matrix, and the orthogonal/unitary matrix Z is returned;
 If *compz* = 'V', Z must contain an orthogonal/unitary matrix Z_1 on entry, and the product Z_1^*Z is returned.

n INTEGER. The order of the matrices A and B ($n \geq 0$).

ilo, ihi INTEGER. *ilo* and *ihi* mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns 1:*ilo*-1 and *ihi*+1:*n*. Values of *ilo* and *ihi* are normally set by a previous call to `?ggbal`; otherwise they should be set to 1 and *n* respectively.
 Constraint:

a, b, q, z

If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;
 if $n = 0$, then $ilo = 1$ and $ihi = 0$.

REAL for sgghrd
 DOUBLE PRECISION for dgghrd
 COMPLEX for cgghrd
 DOUBLE COMPLEX for zgghrd.

Arrays:
a(*lda*,*) contains the n -by- n general matrix *A*. The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) contains the n -by- n upper triangular matrix *B*. The second dimension of *b* must be at least $\max(1, n)$.
q(*ldq*,*)
 If *compq* = 'N', then *q* is not referenced.
 If *compq* = 'V', then *q* must contain the orthogonal/unitary matrix Q_1 , typically from the QR factorization of *B*. The second dimension of *q* must be at least $\max(1, n)$.
z(*ldz*,*)
 If *compq* = 'N', then *z* is not referenced.
 If *compq* = 'V', then *z* must contain the orthogonal/unitary matrix Z_1 . The second dimension of *z* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.
ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.
ldq INTEGER. The first dimension of *q*;
 If *compq* = 'N', then $ldq \geq 1$.
 If *compq* = 'I' or 'V', then $ldq \geq \max(1, n)$.
ldz INTEGER. The first dimension of *z*;
 If *compq* = 'N', then $ldz \geq 1$.
 If *compq* = 'I' or 'V', then $ldz \geq \max(1, n)$.

Output Parameters

a

On exit, the upper triangle and the first subdiagonal of *A* are overwritten with the upper Hessenberg matrix H , and the rest is set to zero.

<i>b</i>	On exit, overwritten by the upper triangular matrix $T = Q^H * B * Z$. The elements below the diagonal are set to zero.
<i>q</i>	If <i>compq</i> = 'I', then <i>q</i> contains the orthogonal/unitary matrix Q ; If <i>compq</i> = 'V', then <i>q</i> is overwritten by the product $Q_1 * Q$.
<i>z</i>	If <i>compz</i> = 'I', then <i>z</i> contains the orthogonal/unitary matrix Z ; If <i>compz</i> = 'V', then <i>z</i> is overwritten by the product $Z_1 * Z$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gghrd* interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size (n, n) .
<i>q</i>	Holds the matrix Q of size (n, n) .
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>compq</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>compq</i> = 'I', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted. If present, <i>compq</i> must be equal to 'I' or 'V' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>compq</i> is present and <i>q</i> omitted.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument <i>z</i> must also be present. Note that there will be an error condition if <i>compz</i> is present and <i>z</i> omitted.

?ggbal

Balances a pair of general real or complex matrices.

Syntax

FORTRAN 77:

```
call sggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
call dggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
call cggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
call zggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
```

Fortran 95:

```
call ggbal(a, b [,ilo] [,ihi] [,lscale] [,rscale] [,job] [,info])
```

Description

This routine balances a pair of general real/complex matrices (A, B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to $ilo-1$ and last $ihi+1$ to n elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ilo to ihi to make the rows and columns as close in norm as possible. Both steps are optional. Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

Input Parameters

<i>job</i>	CHARACTER*1. Specifies the operations to be performed on A and B . Must be 'N' or 'P' or 'S' or 'B'. If <i>job</i> = 'N', then no operations are done; simply set $ilo=1$, $ihi=n$, $lscale(i)=1.0$ and $rscale(i)=1.0$ for $i = 1, \dots, n$. If <i>job</i> = 'P', then permute only. If <i>job</i> = 'S', then scale only. If <i>job</i> = 'B', then both permute and scale.
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a, b</i>	REAL for sggbal

DOUBLE PRECISION for dggbal

COMPLEX for cggbal

DOUBLE COMPLEX for zggbal.

Arrays:

$a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$.

$b(ldb,*)$ contains the matrix B . The second dimension of b must be at least $\max(1, n)$.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

ldb INTEGER. The first dimension of b ; at least $\max(1, n)$.

$work$ REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, 6n)$ when $job = 'S'$ or $'B'$, or at least 1 when $job = 'N'$ or $'P'$.

Output Parameters

a, b Overwritten by the balanced matrices A and B , respectively.
If $job = 'N'$, a and b are not referenced.

ilo, ihi INTEGER. ilo and ihi are set to integers such that on exit $a(i, j) = 0$ and $b(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.
If $job = 'N'$ or $'S'$, then $ilo = 1$ and $ihi = n$.

$lscale, rscale$ REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, n)$.

$lscale$ contains details of the permutations and scaling factors applied to the left side of A and B .

If P_j is the index of the row interchanged with row j , and D_j is the scaling factor applied to row j , then

$lscale(j) = P_j$, for $j = 1, \dots, ilo-1$

$= D_j$, for $j = ilo, \dots, ihi$

$= P_j$, for $j = ihi+1, \dots, n$.

$rscale$ contains details of the permutations and scaling factors applied to the right side of A and B .

If P_j is the index of the column interchanged with column j , and D_j is the scaling factor applied to column j , then

$rscale(j) = P_j$, for $j = 1, \dots, ilo-1$
 $= D_j$, for $j = ilo, \dots, ihi$
 $= P_j$, for $j = ihi+1, \dots, n$

The order in which the interchanges are made is n to $ihl+1$, then 1 to $ilo-1$.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggbal` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>lscale</i>	Holds the vector of length (n) .
<i>rscale</i>	Holds the vector of length (n) .
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

?ggbak

Forms the right or left eigenvectors of a generalized eigenvalue problem.

Syntax

FORTRAN 77:

```

call sggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call dggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call cggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call zggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)

```

Fortran 95:

```
call ggbak(v [, ilo] [,ihi] [,lscale] [,rscale] [,job] [,info])
```

Description

This routine forms the right or left eigenvectors of a real/complex generalized eigenvalue problem

$$A*x = \lambda*B*x$$

by backward transformation on the computed eigenvectors of the balanced pair of matrices output by `?ggbal`.

Input Parameters

<i>job</i>	CHARACTER*1. Specifies the type of backward transformation required. Must be 'N', 'P', 'S', or 'B'. If <i>job</i> = 'N', then no operations are done; return. If <i>job</i> = 'P', then do backward transformation for permutation only. If <i>job</i> = 'S', then do backward transformation for scaling only. If <i>job</i> = 'B', then do backward transformation for both permutation and scaling. This argument must be the same as the argument <i>job</i> supplied to <code>?ggbal</code>.
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then <i>v</i> contains left eigenvectors. If <i>side</i> = 'R', then <i>v</i> contains right eigenvectors.
<i>n</i>	INTEGER. The number of rows of the matrix <i>v</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. The integers <i>ilo</i> and <i>ihi</i> determined by <code>?ggbal</code>. Constraint: If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then $ilo = 1$ and $ihi = 0$.
<i>lscale, rscale</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, n)$. The array <i>lscale</i> contains details of the permutations and/or scaling factors applied to the left side of <i>A</i> and <i>B</i>, as returned by <code>?ggbal</code>.

	The array <i>rscale</i> contains details of the permutations and/or scaling factors applied to the right side of <i>A</i> and <i>B</i> , as returned by ?ggbal.
<i>m</i>	INTEGER. The number of columns of the matrix <i>V</i> ($m \geq 0$).
<i>v</i>	REAL for sggbak DOUBLE PRECISION for dggbak COMPLEX for cggbak DOUBLE COMPLEX for zggbak. Array <i>v</i> (<i>ldv</i> ,*). Contains the matrix of right or left eigenvectors to be transformed, as returned by ?tgevc. The second dimension of <i>v</i> must be at least max(1, <i>m</i>).
<i>ldv</i>	INTEGER. The first dimension of <i>v</i> ; at least max(1, <i>n</i>).

Output Parameters

<i>v</i>	Overwritten by the transformed eigenvectors
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine ggbak interface are the following:

<i>v</i>	Holds the matrix <i>V</i> of size (<i>n</i> , <i>m</i>).
<i>lscale</i>	Holds the vector of length (<i>n</i>).
<i>rscale</i>	Holds the vector of length (<i>n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.
<i>side</i>	If omitted, this argument is restored based on the presence of arguments <i>lscale</i> and <i>rscale</i> as follows: <i>side</i> = 'L', if <i>lscale</i> is present and <i>rscale</i> omitted,

`side = 'R'`, if `lscale` is omitted and `rscale` present.

Note that there will be an error condition if both `lscale` and `rscale` are present or if they both are omitted.

?hgeqz

Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H, T) .

Syntax

FORTRAN 77:

```
call shgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alphas, alphai,
beta, q, ldq, z, ldz, work, lwork, info)

call dhgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alphas, alphai,
beta, q, ldq, z, ldz, work, lwork, info)

call chgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alpha, beta, q,
ldq, z, ldz, work, lwork, rwork, info)

call zhgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alpha, beta, q,
ldq, z, ldz, work, lwork, rwork, info)
```

Fortran 95:

```
call hgeqz(h, t [,ilo] [,ihi] [,alphar] [,alphai] [,beta] [,q] [,z] [,job]
[,compq] [,compz] [,info])

call hgeqz(h, t [,ilo] [,ihi] [,alpha] [,beta] [,q] [,z] [,job] [,compq] [,
compz] [,info])
```

Description

This routine computes the eigenvalues of a real/complex matrix pair (H, T) , where H is an upper Hessenberg matrix and T is upper triangular, using the double-shift version (for real flavors) or single-shift version (for complex flavors) of the QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real/complex matrix pair (A, B) :

$$A = Q_1^* H Z_1^H, B = Q_1^* T Z_1^H,$$

as computed by ?gghrd.

For real flavors:

If *job* = 'S', then the Hessenberg-triangular pair (*H*, *T*) is also reduced to generalized Schur form,

$$H = Q^* S^* Z^T, T = Q^* P^* Z^T,$$

where *Q* and *Z* are orthogonal matrices, *P* is an upper triangular matrix, and *S* is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks. The 1-by-1 blocks correspond to real eigenvalues of the matrix pair (*H*, *T*) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of *P* corresponding to 2-by-2 blocks of *S* are reduced to positive diagonal form, that is, if *S*(*j*+1,*j*) is non-zero, then *P*(*j*+1, *j*) = *P*(*j*, *j*+1) = 0, *P*(*j*, *j*) > 0, and *P*(*j*+1, *j*+1) > 0.

For complex flavors:

If *job* = 'S', then the Hessenberg-triangular pair (*H*, *T*) is also reduced to generalized Schur form,

$$H = Q^* S^* Z^H, T = Q^* P^* Z^H,$$

where *Q* and *Z* are unitary matrices, and *S* and *P* are upper triangular.

For all function flavors:

Optionally, the orthogonal/unitary matrix *Q* from the generalized Schur factorization may be postmultiplied into an input matrix *Q*₁, and the orthogonal/unitary matrix *Z* may be postmultiplied into an input matrix *Z*₁.

If *Q*₁ and *Z*₁ are the orthogonal/unitary matrices from ?gghrd that reduced the matrix pair (*A*, *B*) to generalized upper Hessenberg form, then the output matrices *Q*₁*Q* and *Z*₁*Z* are the orthogonal/unitary factors from the generalized Schur factorization of (*A*, *B*):

$$A = (Q_1 Q)^* S^* (Z_1 Z)^H, B = (Q_1 Q)^* P^* (Z_1 Z)^H.$$

To avoid overflow, eigenvalues of the matrix pair (*H*, *T*) (equivalently, of (*A*, *B*)) are computed as a pair of values (*alpha*, *beta*). For *chgeqz*/*zhgeqz*, *alpha* and *beta* are complex, and for *shgeqz*/*dhgeqz*, *alpha* is complex and *beta* real. If *beta* is nonzero, $\lambda = \alpha/\beta$ is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

$$A^* x = \lambda^* B^* x$$

and if *alpha* is nonzero, $\mu = \beta/\alpha$ is an eigenvalue of the alternate form of the GNEP

$$\mu^* A^* y = B^* y.$$

Real eigenvalues (for real flavors) or the values of *alpha* and *beta* for the *i*-th eigenvalue (for complex flavors) can be read directly from the generalized Schur form:

$$\alpha = S(i,i), \beta = P(i,i).$$

Input Parameters

<i>job</i>	CHARACTER*1. Specifies the operations to be performed. Must be 'E' or 'S'. If <i>job</i> = 'E', then compute eigenvalues only; If <i>job</i> = 'S', then compute eigenvalues and the Schur form.
<i>compq</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compq</i> = 'N', left Schur vectors (<i>q</i>) are not computed; If <i>compq</i> = 'I', <i>q</i> is initialized to the unit matrix and the matrix of left Schur vectors of (<i>H</i> , <i>T</i>) is returned; If <i>compq</i> = 'V', <i>q</i> must contain an orthogonal/unitary matrix Q_1 on entry and the product Q_1^*Q is returned.
<i>compz</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compz</i> = 'N', right Schur vectors (<i>z</i>) are not computed; If <i>compz</i> = 'I', <i>z</i> is initialized to the unit matrix and the matrix of right Schur vectors of (<i>H</i> , <i>T</i>) is returned; If <i>compz</i> = 'V', <i>z</i> must contain an orthogonal/unitary matrix Z_1 on entry and the product Z_1^*Z is returned.
<i>n</i>	INTEGER. The order of the matrices <i>H</i> , <i>T</i> , <i>Q</i> , and <i>Z</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. <i>ilo</i> and <i>ihi</i> mark the rows and columns of <i>H</i> which are in Hessenberg form. It is assumed that <i>H</i> is already upper triangular in rows and columns 1: <i>ilo</i> -1 and <i>ihi</i> +1: <i>n</i> . Constraint: If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then $ilo = 1$ and $ihi = 0$.
<i>h, t, q, z, work</i>	REAL for shgeqz DOUBLE PRECISION for dhgeqz COMPLEX for chgeqz

DOUBLE COMPLEX for zhgeqz.

Arrays:

On entry, $h(ldh,*)$ contains the n -by- n upper Hessenberg matrix H .

The second dimension of h must be at least $\max(1, n)$.

On entry, $t(ldt,*)$ contains the n -by- n upper triangular matrix T .

The second dimension of t must be at least $\max(1, n)$.

$q(ldq,*)$:

On entry, if $compq = 'V'$, this array contains the orthogonal/unitary matrix Q_1 used in the reduction of (A, B) to generalized Hessenberg form.

If $compq = 'N'$, then q is not referenced.

The second dimension of q must be at least $\max(1, n)$.

$z(ldz,*)$:

On entry, if $compz = 'V'$, this array contains the orthogonal/unitary matrix Z_1 used in the reduction of (A, B) to generalized Hessenberg form.

If $compz = 'N'$, then z is not referenced.

The second dimension of z must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

ldh

INTEGER. The first dimension of h ; at least $\max(1, n)$.

ldt

INTEGER. The first dimension of t ; at least $\max(1, n)$.

ldq

INTEGER. The first dimension of q ;

If $compq = 'N'$, then $ldq \geq 1$.

If $compq = 'I'$ or $'V'$, then $ldq \geq \max(1, n)$.

ldz

INTEGER. The first dimension of z ;

If $compz = 'N'$, then $ldz \geq 1$.

If $compz = 'I'$ or $'V'$, then $ldz \geq \max(1, n)$.

$lwork$

INTEGER. The dimension of the array $work$.

$lwork \geq \max(1, n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`. See *Application Notes* for details.

`rwork`

REAL for `chgeqz`

DOUBLE PRECISION for `zhgeqz`.

Workspace array, DIMENSION at least $\max(1, n)$. Used in complex flavors only.

Output Parameters

`h`

For real flavors:

If `job = 'S'`, then, on exit, `h` contains the upper quasi-triangular matrix `s` from the generalized Schur factorization; 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $h(i, i) = h(i+1, i+1)$ and $h(i+1, i) * h(i, i+1) < 0$.

If `job = 'E'`, then on exit the diagonal blocks of `h` match those of `s`, but the rest of `h` is unspecified.

For complex flavors:

If `job = 'S'`, then, on exit, `h` contains the upper triangular matrix `s` from the generalized Schur factorization.

If `job = 'E'`, then on exit the diagonal of `h` matches that of `s`, but the rest of `h` is unspecified.

`t`

If `job = 'S'`, then, on exit, `t` contains the upper triangular matrix `p` from the generalized Schur factorization.

For real flavors:

2-by-2 diagonal blocks of `p` corresponding to 2-by-2 blocks of `s` are reduced to positive diagonal form, that is, if $h(j+1, j)$ is non-zero, then $t(j+1, j) = t(j, j+1) = 0$ and $t(j, j)$ and $t(j+1, j+1)$ will be positive.

If `job = 'E'`, then on exit the diagonal blocks of `t` match those of `p`, but the rest of `t` is unspecified.

For complex flavors:

if `job = 'E'`, then on exit the diagonal of `t` matches that of `p`, but the rest of `t` is unspecified.

alphar, alphai

REAL for shgeqz;
 DOUBLE PRECISION for dhgeqz.
 Arrays, DIMENSION at least $\max(1, n)$. The real and imaginary parts, respectively, of each scalar *alpha* defining an eigenvalue of GNEP.
 If *alphai*(*j*) is zero, then the *j*-th eigenvalue is real; if positive, then the *j*-th and (*j*+1)-th eigenvalues are a complex conjugate pair, with
 $\text{alphai}(j+1) = -\text{alphai}(j)$.

alpha

COMPLEX for chgeqz;
 DOUBLE COMPLEX for zhgeqz.
 Array, DIMENSION at least $\max(1, n)$.
 The complex scalars *alpha* that define the eigenvalues of GNEP. $\text{alphai}(i) = S(i, i)$ in the generalized Schur factorization.

beta

REAL for shgeqz
 DOUBLE PRECISION for dhgeqz
 COMPLEX for chgeqz
 DOUBLE COMPLEX for zhgeqz.
 Array, DIMENSION at least $\max(1, n)$.
For real flavors:
 The scalars *beta* that define the eigenvalues of GNEP. Together, the quantities $\alpha = (\text{alphar}(j), \text{alphai}(j))$ and $\beta = \text{beta}(j)$ represent the *j*-th eigenvalue of the matrix pair (*A*,*B*), in one of the forms $\lambda = \alpha/\beta$ or $\mu = \beta/\alpha$. Since either λ or μ may overflow, they should not, in general, be computed.
For complex flavors:
 The real non-negative scalars *beta* that define the eigenvalues of GNEP.
 $\text{beta}(i) = P(i, i)$ in the generalized Schur factorization. Together, the quantities $\alpha = \text{alpha}(j)$ and $\beta = \text{beta}(j)$ represent the *j*-th eigenvalue of the matrix pair (*A*,*B*), in one of the forms $\lambda = \alpha/\beta$ or $\mu = \beta/\alpha$. Since either λ or μ may overflow, they should not, in general, be computed.

<i>q</i>	On exit, if <i>compq</i> = 'I', <i>q</i> is overwritten by the orthogonal/unitary matrix of left Schur vectors of the pair (<i>H</i> , <i>T</i>), and if <i>compq</i> = 'V', <i>q</i> is overwritten by the orthogonal/unitary matrix of left Schur vectors of (<i>A</i> , <i>B</i>).
<i>z</i>	On exit, if <i>compz</i> = 'I', <i>z</i> is overwritten by the orthogonal/unitary matrix of right Schur vectors of the pair (<i>H</i> , <i>T</i>), and if <i>compz</i> = 'V', <i>z</i> is overwritten by the orthogonal/unitary matrix of right Schur vectors of (<i>A</i> , <i>B</i>).
<i>work</i> (1)	If <i>info</i> ≥ 0, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, ..., <i>n</i> , the <i>QZ</i> iteration did not converge. (<i>H</i> , <i>T</i>) is not in Schur form, but <i>alphar</i> (<i>i</i>), <i>alphai</i> (<i>i</i>) (for real flavors), <i>alpha</i> (<i>i</i>) (for complex flavors), and <i>beta</i> (<i>i</i>), <i>i</i> = <i>info</i> +1, ..., <i>n</i> should be correct. If <i>info</i> = <i>n</i> +1, ..., 2 <i>n</i> , the shift calculation failed. (<i>H</i> , <i>T</i>) is not in Schur form, but <i>alphar</i> (<i>i</i>), <i>alphai</i> (<i>i</i>) (for real flavors), <i>alpha</i> (<i>i</i>) (for complex flavors), and <i>beta</i> (<i>i</i>), <i>i</i> = <i>info</i> - <i>n</i> +1, ..., <i>n</i> should be correct.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hgeqz* interface are the following:

<i>h</i>	Holds the matrix <i>H</i> of size (<i>n</i> , <i>n</i>).
<i>t</i>	Holds the matrix <i>T</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alphai</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alpha</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).

<i>z</i>	Holds the matrix <i>z</i> of size (n, n) .
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>job</i>	Must be 'E' or 'S'. The default value is 'E'.
<i>compq</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>compq</i> = 'I', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted. If present, <i>compq</i> must be equal to 'I' or 'V' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>compq</i> is present and <i>q</i> omitted.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument <i>z</i> must also be present. Note an error condition if <i>compz</i> is present and <i>z</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgevc

Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices.

Syntax

FORTRAN 77:

```
call stgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, info)

call dtgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, info)

call ctgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, rwork, info)

call ztgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, rwork, info)
```

Fortran 95:

```
call tgevc(s, p [,howmny] [,select] [,vl] [,vr] [,m] [,info])
```

Description

This routine computes some or all of the right and/or left eigenvectors of a pair of real/complex matrices (S, P) , where S is quasi-triangular (for real flavors) or upper triangular (for complex flavors) and P is upper triangular.

Matrix pairs of this type are produced by the generalized Schur factorization of a real/complex matrix pair (A, B) :

$$A = Q^* S^* Z^H, B = Q^* P^* Z^H$$

as computed by ?gghrd plus ?hgeqz.

The right eigenvector x and the left eigenvector y of (S, P) corresponding to an eigenvalue w are defined by:

$$S^* x = w^* P^* x, y^H S = w^* y^H P$$

The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks or diagonal elements of S and P .

This routine returns the matrices X and/or Y of right and left eigenvectors of (S, P) , or the products Z^*X and/or Q^*Y , where Z and Q are input matrices.

If Q and Z are the orthogonal/unitary factors from the generalized Schur factorization of a matrix pair (A, B) , then Z^*X and Q^*Y are the matrices of right and left eigenvectors of (A, B) .

Input Parameters

<i>side</i>	CHARACTER*1. Must be 'R', 'L', or 'B'. If <i>side</i> = 'R', compute right eigenvectors only. If <i>side</i> = 'L', compute left eigenvectors only. If <i>side</i> = 'B', compute both right and left eigenvectors.
<i>howmny</i>	CHARACTER*1. Must be 'A', 'B', or 'S'. If <i>howmny</i> = 'A', compute all right and/or left eigenvectors. If <i>howmny</i> = 'B', compute all right and/or left eigenvectors, backtransformed by the matrices in <i>vr</i> and/or <i>vl</i>. If <i>howmny</i> = 'S', compute selected right and/or left eigenvectors, specified by the logical array <i>select</i>.
<i>select</i>	LOGICAL. Array, DIMENSION at least max (1, <i>n</i>). If <i>howmny</i> = 'S', <i>select</i> specifies the eigenvectors to be computed. If <i>howmny</i> = 'A' or 'B', <i>select</i> is not referenced. For real flavors: If <i>omega</i>(<i>j</i>) is a real eigenvalue, the corresponding real eigenvector is computed if <i>select</i>(<i>j</i>) is .TRUE.. If <i>omega</i>(<i>j</i>) and <i>omega</i>(<i>j</i>+1) are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either <i>select</i>(<i>j</i>) or <i>select</i>(<i>j</i>+1) is .TRUE., and on exit <i>select</i>(<i>j</i>) is set to .TRUE. and <i>select</i>(<i>j</i>+1) is set to .FALSE.. For complex flavors: The eigenvector corresponding to the <i>j</i>-th eigenvalue is computed if <i>select</i>(<i>j</i>) is .TRUE..
<i>n</i>	INTEGER. The order of the matrices <i>S</i> and <i>P</i> (<i>n</i> ≥ 0).
<i>s, p, vl, vr, work</i>	REAL for stgevc

DOUBLE PRECISION for dtgevc
 COMPLEX for ctgevc
 DOUBLE COMPLEX for ztgevc.

Arrays:

$s(lds,*)$ contains the matrix S from a generalized Schur factorization as computed by ?hgeqz. This matrix is upper quasi-triangular for real flavors, and upper triangular for complex flavors.

The second dimension of s must be at least $\max(1, n)$.

$p(ldp,*)$ contains the upper triangular matrix P from a generalized Schur factorization as computed by ?hgeqz.

For real flavors, 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S must be in positive diagonal form.

For complex flavors, P must have real diagonal elements.

The second dimension of p must be at least $\max(1, n)$.

If $side = 'L'$ or $'B'$ and $howmny = 'B'$, $vl(ldvl,*)$ must contain an n -by- n matrix Q (usually the orthogonal/unitary matrix Q of left Schur vectors returned by ?hgeqz). The second dimension of vl must be at least $\max(1, mm)$.

If $side = 'R'$, vl is not referenced.

If $side = 'R'$ or $'B'$ and $howmny = 'B'$, $vr(ldvr,*)$ must contain an n -by- n matrix Z (usually the orthogonal/unitary matrix Z of right Schur vectors returned by ?hgeqz). The second dimension of vr must be at least $\max(1, mm)$.

If $side = 'L'$, vr is not referenced.

$work(*)$ is a workspace array.

DIMENSION at least $\max(1, 6*n)$ for real flavors and at least $\max(1, 2*n)$ for complex flavors.

lds INTEGER. The first dimension of s ; at least $\max(1, n)$.

ldp INTEGER. The first dimension of p ; at least $\max(1, n)$.

$ldvl$ INTEGER. The first dimension of vl ;

If $side = 'L'$ or $'B'$, then $ldvl \geq n$.

If $side = 'R'$, then $ldvl \geq 1$.

$ldvr$ INTEGER. The first dimension of vr ;

If $side = 'R'$ or $'B'$, then $ldvr \geq n$.

If $side = 'L'$, then $ldvr \geq 1$.

mm INTEGER. The number of columns in the arrays *vl* and/or *vr* ($mm \geq m$).

rwork REAL for ctgevc DOUBLE PRECISION for ztgevc.
Workspace array, DIMENSION at least $\max(1, 2*n)$. Used in complex flavors only.

Output Parameters

vl On exit, if *side* = 'L' or 'B', *vl* contains:
if *howmny* = 'A', the matrix *Y* of left eigenvectors of (*S*,*P*);
if *howmny* = 'B', the matrix *Q***Y*;
if *howmny* = 'S', the left eigenvectors of (*S*,*P*) specified by *select*, stored consecutively in the columns of *vl*, in the same order as their eigenvalues.
For real flavors:
A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

vr On exit, if *side* = 'R' or 'B', *vr* contains:
if *howmny* = 'A', the matrix *X* of right eigenvectors of (*S*,*P*);
if *howmny* = 'B', the matrix *Z***X*;
if *howmny* = 'S', the right eigenvectors of (*S*,*P*) specified by *select*, stored consecutively in the columns of *vr*, in the same order as their eigenvalues.
For real flavors:
A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

m INTEGER. The number of columns in the arrays *vl* and/or *vr* actually used to store the eigenvectors.
If *howmny* = 'A' or 'B', *m* is set to *n*.
For real flavors:
Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.
For complex flavors:
Each selected eigenvector occupies one column.

info INTEGER.
If *info* = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

For real flavors:

if $info = i > 0$, the 2-by-2 block ($i:i+1$) does not have a complex eigenvalue.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgevc` interface are the following:

<i>s</i>	Holds the matrix <i>S</i> of size (n, n) .
<i>p</i>	Holds the matrix <i>P</i> of size (n, n) .
<i>select</i>	Holds the vector of length (n) .
<i>vl</i>	Holds the matrix <i>VL</i> of size (n, mm) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, mm) .
<i>side</i>	Restored based on the presence of arguments <i>vl</i> and <i>vr</i> as follows: <i>side</i> = 'B', if both <i>vl</i> and <i>vr</i> are present, <i>side</i> = 'L', if <i>vl</i> is present and <i>vr</i> omitted, <i>side</i> = 'R', if <i>vl</i> is omitted and <i>vr</i> present, Note that there will be an error condition if both <i>vl</i> and <i>vr</i> are omitted.
<i>howmny</i>	If omitted, this argument is restored based on the presence of argument <i>select</i> as follows: <i>howmny</i> = 'S', if <i>select</i> is present, <i>howmny</i> = 'A', if <i>select</i> is omitted. If present, <i>howmny</i> must be equal to 'A' or 'B' and the argument <i>select</i> must be omitted. Note that there will be an error condition if both <i>howmny</i> and <i>select</i> are present.

?tgexc

Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.

Syntax

FORTRAN 77:

```
call stgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, work,
            lwork, info)

call dtgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, work,
            lwork, info)

call ctgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, info)

call ztgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, info)
```

Fortran 95:

```
call tgexc(a, b [,ifst] [,ilst] [,z] [,q] [,info])
```

Description

This routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A,B) using an orthogonal/unitary equivalence transformation

$$(A, B) = Q^* (A, B) * Z^H,$$

so that the diagonal block of (A, B) with row index *ifst* is moved to row *ilst*. Matrix pair (A, B) must be in a generalized real-Schur/Schur canonical form (as returned by ?gges), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks and B is upper triangular. Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$Q(\text{in}) * A(\text{in}) * Z(\text{in})^T = Q(\text{out}) * A(\text{out}) * Z(\text{out})^T$

$Q(\text{in}) * B(\text{in}) * Z(\text{in})^T = Q(\text{out}) * B(\text{out}) * Z(\text{out})^T$.

Input Parameters

<i>wantq, wantz</i>	LOGICAL. If <i>wantq</i> = .TRUE., update the left transformation matrix Q; If <i>wantq</i> = .FALSE., do not update Q;

If *wantz* = .TRUE., update the right transformation matrix *Z*;
 If *wantz* = .FALSE., do not update *Z*.

n
 INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

a, *b*, *q*,
 REAL for stgexc
 DOUBLE PRECISION for dtgexc
 COMPLEX for ctgexc
 DOUBLE COMPLEX for ztgexc.

Arrays:
a(*lda*,*) contains the matrix *A*.
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) contains the matrix *B*. The second dimension of *b*
 must be at least $\max(1, n)$.
q(*ldq*,*)
 If *wantq* = .FALSE., then *q* is not referenced.
 If *wantq* = .TRUE., then *q* must contain the
 orthogonal/unitary matrix *Q*.
 The second dimension of *q* must be at least $\max(1, n)$.
z(*ldz*,*)
 If *wantz* = .FALSE., then *z* is not referenced.
 If *wantz* = .TRUE., then *z* must contain the
 orthogonal/unitary matrix *Z*.
 The second dimension of *z* must be at least $\max(1, n)$.

lda
 INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb
 INTEGER. The first dimension of *b*; at least $\max(1, n)$.

ldq
 INTEGER. The first dimension of *q*;
 If *wantq* = .FALSE., then $ldq \geq 1$.
 If *wantq* = .TRUE., then $ldq \geq \max(1, n)$.

ldz
 INTEGER. The first dimension of *z*;
 If *wantz* = .FALSE., then $ldz \geq 1$.
 If *wantz* = .TRUE., then $ldz \geq \max(1, n)$.

ifst, *ilst*
 INTEGER. Specify the reordering of the diagonal blocks of
 (*A*, *B*). The block with row index *ifst* is moved to row *ilst*,
 by a sequence of swapping between adjacent blocks.
 Constraint: $1 \leq ifst, ilst \leq n$.

<i>work</i>	REAL for <code>stgexc</code> ; DOUBLE PRECISION for <code>dtgexc</code> . Workspace array, DIMENSION (<i>lwork</i>). Used in real flavors only.
<i>lwork</i>	INTEGER. The dimension of <i>work</i> ; must be at least $4n + 16$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for details.

Output Parameters

<i>a, b</i>	Overwritten by the updated matrices <i>A</i> and <i>B</i> .
<i>ifst, ilst</i>	Overwritten for real flavors only. If <i>ifst</i> pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; <i>ilst</i> always points to the first row of the block in its final position (which may differ from its input value by ± 1).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, the transformed matrix pair (<i>A</i> , <i>B</i>) would be too far from generalized Schur form; the problem is ill-conditioned. (<i>A</i> , <i>B</i>) may have been partially reordered, and <i>ilst</i> points to the first row of the current position of the block being moved.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgexc` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).

q	Holds the matrix Q of size (n, n) .
$wantq$	Restored based on the presence of the argument q as follows: $wantq = .TRUE$, if q is present, $wantq = .FALSE$, if q is omitted.
$wantz$	Restored based on the presence of the argument z as follows: $wantz = .TRUE$, if z is present, $wantz = .FALSE$, if z is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsgen

Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B).

Syntax

FORTTRAN 77:

```
call stgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alphas, alphas,
beta, q, ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)

call dtgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alphas, alphas,
beta, q, ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)

call ctgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alpha, beta, q,
ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)

call ztgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alpha, beta, q,
ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call tgsgen(a, b, select [,alphas] [,alphas] [,beta] [,ijob] [,q] [,z] [,pl]
[,pr] [,dif] [,m] [,info])

call tgsgen(a, b, select [,alpha] [,beta] [,ijob] [,q] [,z] [,pl] [,pr] [, dif]
[,m] [,info])
```

Description

This routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A, B) (in terms of an orthogonal/unitary equivalence transformation $Q^* (A, B) Z$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A, B). The leading columns of Q and Z form orthonormal/unitary bases of the corresponding left and right eigenspaces (deflating subspaces).

(A, B) must be in generalized real-Schur/Schur canonical form (as returned by ?gges), that is, A and B are both upper triangular.

?tgsgen also computes the generalized eigenvalues

$\omega_j = (\text{alphas}(j) + \text{alphas}(j)*i)/\text{beta}(j)$ (for real flavors)

$\omega_j = \alpha(j)/\beta(j)$ (for complex flavors)

of the reordered matrix pair (A, B) .

Optionally, the routine computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, that is, the separation(s) between the matrix pairs (A_{11}, B_{11}) and (A_{22}, B_{22}) that correspond to the selected cluster and the eigenvalues outside the cluster, respectively, and norms of "projections" onto left and right eigenspaces with respect to the selected cluster in the (1,1)-block.

Input Parameters

ijob INTEGER. Specifies whether condition numbers are required for the cluster of eigenvalues (*pl* and *pr*) or the deflating subspaces *Difu* and *Difl*.
 If *ijob* = 0, only reorder with respect to *select*;
 If *ijob* = 1, reciprocal of norms of "projections" onto left and right eigenspaces with respect to the selected cluster (*pl* and *pr*);
 If *ijob* = 2, compute upper bounds on *Difu* and *Difl*, using F-norm-based estimate (*dif* (1:2));
 If *ijob* = 3, compute estimate of *Difu* and *Difl*, using 1-norm-based estimate (*dif* (1:2)). This option is about 5 times as expensive as *ijob* = 2;
 If *ijob* = 4, compute *pl*, *pr* and *dif* (i.e., options 0, 1 and 2 above). This is an economic version to get it all;
 If *ijob* = 5, compute *pl*, *pr* and *dif* (i.e., options 0, 1 and 3 above).

wantq, wantz LOGICAL.
 If *wantq* = .TRUE., update the left transformation matrix *Q*;
 If *wantq* = .FALSE., do not update *Q*;
 If *wantz* = .TRUE., update the right transformation matrix *Z*;
 If *wantz* = .FALSE., do not update *Z*.

select LOGICAL.
 Array, DIMENSION at least max (1, *n*). Specifies the eigenvalues in the selected cluster.

To select an eigenvalue $\omega(j)$, $\text{select}(j)$ must be `.TRUE.` For real flavors: to select a complex conjugate pair of eigenvalues $\omega(j)$ and $\omega(j+1)$ (corresponding 2 by 2 diagonal block), $\text{select}(j)$ and/or $\text{select}(j+1)$ must be set to `.TRUE.`; the complex conjugate $\omega(j)$ and $\omega(j+1)$ must be either both included in the cluster or both excluded.

n INTEGER. The order of the matrices A and B ($n \geq 0$).

a, b, q, z, work REAL for stgsen
DOUBLE PRECISION for dtgsen
COMPLEX for ctgsen
DOUBLE COMPLEX for ztgsen.

Arrays:
 $a(\text{lda},*)$ contains the matrix A .
 For real flavors: A is upper quasi-triangular, with (A, B) in generalized real Schur canonical form.
 For complex flavors: A is upper triangular, in generalized Schur canonical form.
 The second dimension of a must be at least $\max(1, n)$.
 $b(\text{ldb},*)$ contains the matrix B .
 For real flavors: B is upper triangular, with (A, B) in generalized real Schur canonical form.
 For complex flavors: B is upper triangular, in generalized Schur canonical form. The second dimension of b must be at least $\max(1, n)$.
 $q(\text{ldq},*)$
 If $\text{wantq} = \text{.TRUE.}$, then q is an n -by- n matrix;
 If $\text{wantq} = \text{.FALSE.}$, then q is not referenced.
 The second dimension of q must be at least $\max(1, n)$.
 $z(\text{ldz},*)$
 If $\text{wantz} = \text{.TRUE.}$, then z is an n -by- n matrix;
 If $\text{wantz} = \text{.FALSE.}$, then z is not referenced.
 The second dimension of z must be at least $\max(1, n)$.
 work is a workspace array, its dimension $\max(1, \text{lwork})$.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

ldb INTEGER. The first dimension of b ; at least $\max(1, n)$.

<i>ldq</i>	INTEGER. The first dimension of <i>q</i>; $ldq \geq 1$. If <i>wantq</i> = <code>.TRUE.</code>, then $ldq \geq \max(1, n)$.
<i>ldz</i>	INTEGER. The first dimension of <i>z</i>; $ldz \geq 1$. If <i>wantz</i> = <code>.TRUE.</code>, then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. <i>For real flavors:</i> If <i>ijob</i> = 1, 2, or 4, $lwork \geq \max(4n+16, 2m(n-m))$. If <i>ijob</i> = 3 or 5, $lwork \geq \max(4n+16, 4m(n-m))$. <i>For complex flavors:</i> If <i>ijob</i> = 1, 2, or 4, $lwork \geq \max(1, 2m(n-m))$. If <i>ijob</i> = 3 or 5, $lwork \geq \max(1, 4m(n-m))$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, its dimension $\max(1, liwork)$. If <i>ijob</i> = 0, <i>iwork</i> is not referenced.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i>. <i>For real flavors:</i> If <i>ijob</i> = 1, 2, or 4, $liwork \geq n+6$. If <i>ijob</i> = 3 or 5, $liwork \geq \max(n+6, 2m(n-m))$. <i>For complex flavors:</i> If <i>ijob</i> = 1, 2, or 4, $liwork \geq n+2$. If <i>ijob</i> = 3 or 5, $liwork \geq \max(n+2, 2m(n-m))$. If <i>liwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.

Output Parameters

<i>a</i> , <i>b</i>	Overwritten by the reordered matrices <i>A</i> and <i>B</i> , respectively.

<i>alphar, alphai</i>	REAL for stgsen; DOUBLE PRECISION for dtgsen. Arrays, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i>.
<i>alpha</i>	COMPLEX for ctgsen; DOUBLE COMPLEX for ztgsen. Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i>.
<i>beta</i>	REAL for stgsen DOUBLE PRECISION for dtgsen COMPLEX for ctgsen DOUBLE COMPLEX for ztgsen. Array, DIMENSION at least $\max(1, n)$. For real flavors: On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues. $\text{alphar}(j) + \text{alphai}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}(j)$ is zero, then the j-th eigenvalue is real; if positive, then the j-th and $(j+1)$-st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative. For complex flavors: The diagonal elements of A and B, respectively, when the pair (A, B) has been reduced to generalized Schur form. $\text{alpha}(i)/\text{beta}(i)$, $i=1, \dots, n$ are the generalized eigenvalues.
<i>q</i>	If <i>wantq</i> = .TRUE., then, on exit, <i>q</i> has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B). The leading m columns of <i>q</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).

<i>z</i>	If <i>wantz</i> = .TRUE., then, on exit, <i>z</i> has been postmultiplied by the left orthogonal transformation matrix which reorder (<i>A</i>, <i>B</i>). The leading <i>m</i> columns of <i>z</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).
<i>m</i>	INTEGER. The dimension of the specified pair of left and right eigen-spaces (deflating subspaces); $0 \leq m \leq n$.
<i>pl, pr</i>	REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. If <i>ijob</i> = 1, 4, or 5, <i>pl</i> and <i>pr</i> are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. $0 < pl, pr \leq 1$. If <i>m</i> = 0 or <i>m</i> = <i>n</i>, <i>pl</i> = <i>pr</i> = 1. If <i>ijob</i> = 0, 2 or 3, <i>pl</i> and <i>pr</i> are not referenced
<i>dif</i>	REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Array, DIMENSION (2). If <i>ijob</i> ≥ 2, <i>dif</i>(1:2) store the estimates of <i>Difu</i> and <i>Difl</i>. If <i>ijob</i> = 2 or 4, <i>dif</i>(1:2) are F-norm-based upper bounds on <i>Difu</i> and <i>Difl</i>. If <i>ijob</i> = 3 or 5, <i>dif</i>(1:2) are 1-norm-based estimates of <i>Difu</i> and <i>Difl</i>. If <i>m</i> = 0 or <i>n</i>, <i>dif</i>(1:2) = F-norm([<i>A</i>, <i>B</i>]). If <i>ijob</i> = 0 or 1, <i>dif</i> is not referenced.
<i>work</i> (1)	If <i>ijob</i> is not 0 and <i>info</i> = 0, on exit, <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>iwork</i> (1)	If <i>ijob</i> is not 0 and <i>info</i> = 0, on exit, <i>iwork</i>(1) contains the minimum value of <i>liwork</i> required for optimum performance. Use this <i>liwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

If *info* = 1, Reordering of (*A*, *B*) failed because the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is very ill-conditioned. (*A*, *B*) may have been partially reordered.
If requested, 0 is returned in *dif*(*), *p1* and *pr*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tgssn* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>select</i>	Holds the vector of length (<i>n</i>).
<i>alphar</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alphai</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alpha</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>dif</i>	Holds the vector of length (2).
<i>ijob</i>	Must be 0, 1, 2, 3, 4, or 5. The default value is 0.
<i>wantq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>wantq</i> = .TRUE, if <i>q</i> is present, <i>wantq</i> = .FALSE, if <i>q</i> is omitted.
<i>wantz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>wantz</i> = .TRUE, if <i>z</i> is present, <i>wantz</i> = .FALSE, if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsyl

Solves the generalized Sylvester equation.

Syntax

FORTRAN 77:

```
call stgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, dif, work, lwork, iwork, info)
```

```
call dtgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, dif, work, lwork, iwork, info)
```

```
call ctgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, dif, work, lwork, iwork, info)
```

```
call ztgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,
scale, dif, work, lwork, iwork, info)
```

Fortran 95:

```
call tgsyl(a, b, c, d, e, f [,ijob] [,trans] [,scale] [,dif] [,info])
```

Description

This routine solves the generalized Sylvester equation:

$$A^*R - L^*B = \text{scale} * C$$

$$D^*R - L^*E = \text{scale} * F$$

where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively, with real/complex entries. (A, D) and (B, E) must be in generalized real-Schur/Schur canonical form, that is, A, B are upper quasi-triangular/triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F) . The factor $scale$, $0 \leq scale \leq 1$, is an output scaling factor chosen to avoid overflow.

In matrix notation the above equation is equivalent to the following: solve $Z * x = scale * b$, where Z is defined as

$$Z = \begin{pmatrix} \text{kron}(I_n, A) - \text{kron}(B', I_m) \\ \text{kron}(I_n, D) - \text{kron}(E', I_m) \end{pmatrix}$$

Here I_k is the identity matrix of size k and x' is the transpose/conjugate-transpose of x . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

If $trans = 'T'$ (for real flavors), or $trans = 'C'$ (for complex flavors), the routine `?tgstyl` solves the transposed/conjugate-transposed system $Z' * y = scale * b$, which is equivalent to solve for R and L in

$$A' * R + D' * L = scale * C$$

$$R * B' + L * E' = scale * (-F)$$

This case ($trans = 'T'$ for `stgsyl/dtgsyl` or $trans = 'C'$ for `ctgsyl/ztgsyl`) is used to compute an one-norm-based estimate of $\text{Dif}[(A, D), (B, E)]$, the separation between the matrix pairs (A, D) and (B, E) , using [slacon/clacon](#).

If $ijob \geq 1$, `?tgstyl` computes a Frobenius norm-based estimate of $\text{Dif}[(A, D), (B, E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z . This is a level 3 BLAS algorithm.

Input Parameters

trans CHARACTER*1. Must be 'N', 'T', or 'C'.
 If *trans* = 'N', solve the generalized Sylvester equation.
 If *trans* = 'T', solve the 'transposed' system (for real flavors only).

If *trans* = 'C', solve the 'conjugate transposed' system (for complex flavors only).

ijob INTEGER. Specifies what kind of functionality to be performed:
 If *ijob* = 0, solve the generalized Sylvester equation only;
 If *ijob* = 1, perform the functionality of *ijob* = 0 and *ijob* = 3;
 If *ijob* = 2, perform the functionality of *ijob* = 0 and *ijob* = 4;
 If *ijob* = 3, only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (look ahead strategy is used);
 If *ijob* = 4, only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (?gecon on sub-systems is used). If *trans* = 'T' or 'C', *ijob* is not referenced.

m INTEGER. The order of the matrices *A* and *D*, and the row dimension of the matrices *C*, *F*, *R* and *L*.

n INTEGER. The order of the matrices *B* and *E*, and the column dimension of the matrices *C*, *F*, *R* and *L*.

a, *b*, *c*, *d*, *e*, *f*, *work* REAL for stgsyl
 DOUBLE PRECISION for dtgsyl
 COMPLEX for ctgsyl
 DOUBLE COMPLEX for ztgsyl.

Arrays:
a(*lda*,*) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix *A*.
 The second dimension of *a* must be at least $\max(1, m)$.
b(*ldb*,*) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix *B*. The second dimension of *b* must be at least $\max(1, n)$.
c(*ldc*,*) contains the right-hand-side of the first matrix equation in the generalized Sylvester equation (as defined by *trans*)
 The second dimension of *c* must be at least $\max(1, n)$.
d(*ldd*,*) contains the upper triangular matrix *D*.
 The second dimension of *d* must be at least $\max(1, m)$.
e(*lde*,*) contains the upper triangular matrix *E*.
 The second dimension of *e* must be at least $\max(1, n)$.

$f(ldf,*)$ contains the right-hand-side of the second matrix equation in the generalized Sylvester equation (as defined by *trans*)

The second dimension of f must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The first dimension of b ; at least $\max(1, n)$.
ldc	INTEGER. The first dimension of c ; at least $\max(1, m)$.
ldd	INTEGER. The first dimension of d ; at least $\max(1, m)$.
lde	INTEGER. The first dimension of e ; at least $\max(1, n)$.
ldf	INTEGER. The first dimension of f ; at least $\max(1, m)$.
$lwork$	INTEGER.

The dimension of the array $work$. $lwork \geq 1$.

If $ijob = 1$ or 2 and $trans = 'N'$, $lwork \geq \max(1, 2*m*n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$	INTEGER. Workspace array, DIMENSION at least $(m+n+6)$ for real flavors, and at least $(m+n+2)$ for complex flavors.

Output Parameters

c	If $ijob=0, 1$, or 2 , overwritten by the solution R . If $ijob=3$ or 4 and $trans = 'N'$, c holds R , the solution achieved during the computation of the Dif-estimate.
f	If $ijob=0, 1$, or 2 , overwritten by the solution L . If $ijob=3$ or 4 and $trans = 'N'$, f holds L , the solution achieved during the computation of the Dif-estimate.
dif	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

	On exit, <i>dif</i> is the reciprocal of a lower bound of the reciprocal of the Dif-function, that is, <i>dif</i> is an upper bound of $\text{Dif}[(A, D), (B, E)] = \sigma_{\min}(Z)$, where Z as in (2).
	If <i>ijob</i> = 0, or <i>trans</i> = 'T' (for real flavors), or <i>trans</i> = 'C' (for complex flavors), <i>dif</i> is not touched.
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. On exit, <i>scale</i> is the scaling factor in the generalized Sylvester equation. If $0 < \text{scale} < 1$, <i>c</i> and <i>f</i> hold the solutions <i>R</i> and <i>L</i> , respectively, to a slightly perturbed system but the input matrices <i>A</i> , <i>B</i> , <i>D</i> and <i>E</i> have not been changed. If <i>scale</i> = 0, <i>c</i> and <i>f</i> hold the solutions <i>R</i> and <i>L</i> , respectively, to the homogeneous system with $C = F = 0$. Normally, <i>scale</i> = 1.
<i>work</i> (1)	If <i>info</i> = 0, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> > 0, (<i>A</i> , <i>D</i>) and (<i>B</i> , <i>E</i>) have common or close eigenvalues.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgstyl` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>m</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>d</i>	Holds the matrix <i>D</i> of size (<i>m</i> , <i>m</i>).
<i>e</i>	Holds the matrix <i>E</i> of size (<i>n</i> , <i>n</i>).

<i>f</i>	Holds the matrix <i>F</i> of size (m,n) .
<i>ijob</i>	Must be 0, 1, 2, 3, or 4. The default value is 0.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsna

Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

Syntax

FORTRAN 77:

```
call stgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)

call dtgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)

call ctgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)

call ztgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)
```

Fortran 95:

```
call tgsna(a, b [,s] [,dif] [,vl] [,vr] [,select] [,m] [,info])
```

Description

The real flavors `stgsna/dtgsna` of this routine estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair $(Q^*A^*Z^T, Q^*B^*Z^T)$ with orthogonal matrices Q and Z).

(A, B) must be in generalized real Schur form (as returned by `sgges/dgges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex flavors `ctgsna/ztgsna` estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) . (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Input Parameters

job CHARACTER*1. Specifies whether condition numbers are required for eigenvalues or eigenvectors. Must be 'E' or 'V' or 'B'.
 If *job* = 'E', for eigenvalues only (compute *s*).
 If *job* = 'V', for eigenvectors only (compute *dif*).
 If *job* = 'B', for both eigenvalues and eigenvectors (compute both *s* and *dif*).

howmny CHARACTER*1. Must be 'A' or 'S'.
 If *howmny* = 'A', compute condition numbers for all eigenpairs.
 If *howmny* = 'S', compute condition numbers for selected eigenpairs specified by the logical array *select*.

select LOGICAL.
 Array, DIMENSION at least $\max(1, n)$.
 If *howmny* = 'S', *select* specifies the eigenpairs for which condition numbers are required.
 If *howmny* = 'A', *select* is not referenced.
For real flavors:
 To select condition numbers for the eigenpair corresponding to a real eigenvalue $\omega(j)$, *select*(*j*) must be set to .TRUE.; to select condition numbers corresponding to a

complex conjugate pair of eigenvalues $\text{omega}(j)$ and $\text{omega}(j+1)$, either $\text{select}(j)$ or $\text{select}(j+1)$ must be set to `.TRUE.`

For complex flavors:
 To select condition numbers for the corresponding j -th eigenvalue and/or eigenvector, $\text{select}(j)$ must be set to `.TRUE.`

n INTEGER. The order of the square matrix pair (A, B) ($n \geq 0$).

$a, b, vl, vr, work$ REAL for stgsna
 DOUBLE PRECISION for dtgsna
 COMPLEX for ctgsna
 DOUBLE COMPLEX for ztgsna.

Arrays:
 $a(lda,*)$ contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix A in the pair (A, B) .
 The second dimension of a must be at least $\max(1, n)$.
 $b(l db,*)$ contains the upper triangular matrix B in the pair (A, B) . The second dimension of b must be at least $\max(1, n)$.
 If $job = 'E'$ or $'B'$, $vl(ldvl,*)$ must contain left eigenvectors of (A, B) , corresponding to the eigenpairs specified by $howmny$ and $select$. The eigenvectors must be stored in consecutive columns of vl , as returned by `?tgevc`.
 If $job = 'V'$, vl is not referenced. The second dimension of vl must be at least $\max(1, m)$.
 If $job = 'E'$ or $'B'$, $vr(ldvr,*)$ must contain right eigenvectors of (A, B) , corresponding to the eigenpairs specified by $howmny$ and $select$. The eigenvectors must be stored in consecutive columns of vr , as returned by `?tgevc`.
 If $job = 'V'$, vr is not referenced. The second dimension of vr must be at least $\max(1, m)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
 If $job = 'E'$, $work$ is not referenced.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.
<i>ldvl</i>	INTEGER. The first dimension of <i>vl</i> ; $ldvl \geq 1$. If <i>job</i> = 'E' or 'B', then $ldvl \geq \max(1, n)$.
<i>ldvr</i>	INTEGER. The first dimension of <i>vr</i> ; $ldvr \geq 1$. If <i>job</i> = 'E' or 'B', then $ldvr \geq \max(1, n)$.
<i>mm</i>	INTEGER. The number of elements in the arrays <i>s</i> and <i>dif</i> ($mm \geq m$).
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork \geq \max(1, n)$. If <i>job</i> = 'V' or 'B', $lwork \geq 2*n*(n+2)+16$ for real flavors, and $lwork \geq \max(1, 2*n*n)$ for complex flavors. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $(n+6)$ for real flavors, and at least $(n+2)$ for complex flavors. If <i>ijob</i> = 'E', <i>iwork</i> is not referenced.

Output Parameters

<i>s</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION (<i>mm</i>). If <i>job</i> = 'E' or 'B', contains the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If <i>job</i> = 'V', <i>s</i> is not referenced. <i>For real flavors:</i> For a complex conjugate pair of eigenvalues two consecutive elements of <i>s</i> are set to the same value. Thus, <i>s</i> (<i>j</i>), <i>dif</i> (<i>j</i>), and the <i>j</i> -th columns of <i>vl</i> and <i>vr</i> all correspond to the same eigenpair (but not in general the <i>j</i> -th eigenpair, unless all eigenpairs are selected).

<i>dif</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION (<i>mm</i>). If <i>job</i> = 'V' or 'B', contains the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute <i>dif</i>(<i>j</i>), <i>dif</i>(<i>j</i>) is set to 0; this can only occur when the true value would be very small anyway. If <i>job</i> = 'E', <i>dif</i> is not referenced. For real flavors: For a complex eigenvector, two consecutive elements of <i>dif</i> are set to the same value. For complex flavors: For each eigenvalue/vector specified by <i>select</i>, <i>dif</i> stores a Frobenius norm-based estimate of Difl.
<i>m</i>	INTEGER. The number of elements in the arrays <i>s</i> and <i>dif</i> used to store the specified condition numbers; for each selected eigenvalue one element is used. If <i>howmny</i> = 'A', <i>m</i> is set to <i>n</i>.
<i>work</i> (1)	<i>work</i>(1) If <i>job</i> is not 'E' and <i>info</i> = 0, on exit, <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgсна` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>s</i>	Holds the vector of length (<i>mm</i>).

<i>dif</i>	Holds the vector of length (<i>mm</i>).
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>mm</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>mm</i>).
<i>select</i>	Holds the vector of length (<i>n</i>).
<i>howmny</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>howmny</i> = 'S', if <i>select</i> is present, <i>howmny</i> = 'A', if <i>select</i> is omitted.
<i>job</i>	Restored based on the presence of arguments <i>s</i> and <i>dif</i> as follows: <i>job</i> = 'B', if both <i>s</i> and <i>dif</i> are present, <i>job</i> = 'E', if <i>s</i> is present and <i>dif</i> omitted, <i>job</i> = 'V', if <i>s</i> is omitted and <i>dif</i> present, Note that there will be an error condition if both <i>s</i> and <i>dif</i> are omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Generalized Singular Value Decomposition

This section describes LAPACK computational routines used for finding the generalized singular value decomposition (GSVD) of two matrices *A* and *B* as

$$U^H A Q = D_1 * (0 \ R),$$

$$V^H B Q = D_2 * (0 \ R),$$

where *U*, *V*, and *Q* are orthogonal/unitary matrices, *R* is a nonsingular upper triangular matrix, and *D*₁, *D*₂ are "diagonal" matrices of the structure detailed in the routines description section.

Table 4-7 lists LAPACK routines (Fortran 77 interface) that perform generalized singular value decomposition of matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-7 Computational Routines for Generalized Singular Value Decomposition

Routine name	Operation performed
?ggsvp	Computes the preprocessing decomposition for the generalized SVD
?tgsja	Computes the generalized SVD of two upper triangular or trapezoidal matrices

You can use routines listed in the above table as well as the driver routine [?ggsvd](#) to find the GSVD of a pair of general rectangular matrices.

[?ggsvp](#)

Computes the preprocessing decomposition for the generalized SVD.

Syntax

FORTRAN 77:

```
call sggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, tau, work, info)

call dggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, tau, work, info)

call cggsvp (jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, rwork, tau, work, info)

call zggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, rwork, tau, work, info)
```

Fortran 95:

```
call ggsvp(a, b, tola, tolb [, k] [,l] [,u] [,v] [,q] [,info])
```

Description

This routine computes orthogonal matrices U , V and Q such that

$$U^H A Q = \begin{matrix} & n-k-l & k & l \\ & k & & \\ & l & & \\ m-k-l & & & \end{matrix} \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix}, \quad \text{if } m-k-l \geq 0$$

$$= \begin{matrix} & n-k-l & k & l \\ & k & & \\ m-k & & & \end{matrix} \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \end{pmatrix}, \quad \text{if } m-k-l < 0$$

$$V^H B Q = \begin{matrix} & n-k-l & k & l \\ & l & & \\ p-l & & & \end{matrix} \begin{pmatrix} 0 & 0 & B_{13} \\ 0 & 0 & 0 \end{pmatrix}$$

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m-k-l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal. The sum $k+l$ is equal to the effective numerical rank of the $(m+p)$ -by- n matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine [?ggsvd](#).

Input Parameters

jobu CHARACTER*1. Must be 'U' or 'N'.
 If *jobu* = 'U', orthogonal/unitary matrix U is computed.
 If *jobu* = 'N', U is not computed.

jobv CHARACTER*1. Must be 'V' or 'N'.
 If *jobv* = 'V', orthogonal/unitary matrix V is computed.

<i>jobv</i>	If <i>jobv</i> = 'N', <i>v</i> is not computed. CHARACTER*1. Must be 'Q' or 'N'. If <i>jobq</i> = 'Q', orthogonal/unitary matrix <i>q</i> is computed. If <i>jobq</i> = 'N', <i>q</i> is not computed.
<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>p</i>	INTEGER. The number of rows of the matrix <i>B</i> ($p \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>a, b, tau, work</i>	REAL for sggsvp DOUBLE PRECISION for dggsvp COMPLEX for cggsvp DOUBLE COMPLEX for zggsvp. Arrays: <i>a</i>(<i>lda</i>,*) contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i>(<i>ldb</i>,*) contains the <i>p</i>-by-<i>n</i> matrix <i>B</i>. The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>tau</i>(*) is a workspace array. The dimension of <i>tau</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 3n, m, p)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, p)$.
<i>tola, tolb</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>tola</i> and <i>tolb</i> are the thresholds to determine the effective numerical rank of matrix <i>B</i> and a subblock of <i>A</i>. Generally, they are set to $tola = \max(m, n) * A * \text{MACHEPS}$, $tolb = \max(p, n) * B * \text{MACHEPS}$. The size of <i>tola</i> and <i>tolb</i> may affect the size of backward errors of the decomposition.
<i>ldu</i>	INTEGER. The first dimension of the output array <i>u</i>. <i>ldu</i> $\geq \max(1, m)$ if <i>jobu</i> = 'U'; <i>ldu</i> ≥ 1 otherwise.

<i>ldv</i>	INTEGER. The first dimension of the output array <i>v</i> . <i>ldv</i> $\geq \max(1, p)$ if <i>jobv</i> = 'V'; <i>ldv</i> ≥ 1 otherwise.
<i>ldq</i>	INTEGER. The first dimension of the output array <i>q</i> . <i>ldq</i> $\geq \max(1, n)$ if <i>jobq</i> = 'Q'; <i>ldq</i> ≥ 1 otherwise.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cggsvp DOUBLE PRECISION for zggsvp. Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>a</i>	Overwritten by the triangular (or trapezoidal) matrix described in the <i>Description</i> section.
<i>b</i>	Overwritten by the triangular matrix described in the <i>Description</i> section.
<i>k, l</i>	INTEGER. On exit, <i>k</i> and <i>l</i> specify the dimension of subblocks. The sum <i>k</i> + <i>l</i> is equal to effective numerical rank of $(A^H, B^H)^H$.
<i>u, v, q</i>	REAL for sggsvp DOUBLE PRECISION for dggsvp COMPLEX for cggsvp DOUBLE COMPLEX for zggsvp. Arrays: If <i>jobu</i> = 'U', <i>u</i> (<i>ldu</i> ,*) contains the orthogonal/unitary matrix <i>U</i> . The second dimension of <i>u</i> must be at least $\max(1, m)$. If <i>jobu</i> = 'N', <i>u</i> is not referenced. If <i>jobv</i> = 'V', <i>v</i> (<i>ldv</i> ,*) contains the orthogonal/unitary matrix <i>V</i> . The second dimension of <i>v</i> must be at least $\max(1, m)$. If <i>jobv</i> = 'N', <i>v</i> is not referenced. If <i>jobq</i> = 'Q', <i>q</i> (<i>ldq</i> ,*) contains the orthogonal/unitary matrix <i>Q</i> . The second dimension of <i>q</i> must be at least $\max(1, n)$. If <i>jobq</i> = 'N', <i>q</i> is not referenced.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggsvp* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (p, n) .
<i>u</i>	Holds the matrix <i>U</i> of size (m, m) .
<i>v</i>	Holds the matrix <i>V</i> of size (p, m) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>jobu</i>	Restored based on the presence of the argument <i>u</i> as follows: <i>jobu</i> = 'U', if <i>u</i> is present, <i>jobu</i> = 'N', if <i>u</i> is omitted.
<i>jobv</i>	Restored based on the presence of the argument <i>v</i> as follows: <i>jobz</i> = 'V', if <i>v</i> is present, <i>jobz</i> = 'N', if <i>v</i> is omitted.
<i>jobq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>jobz</i> = 'Q', if <i>q</i> is present, <i>jobz</i> = 'N', if <i>q</i> is omitted.

?tgsja

Computes the generalized SVD of two upper triangular or trapezoidal matrices.

Syntax

FORTRAN 77:

```
call stgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)

call dtgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)

call ctgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)

call ztgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)
```

Fortran 95:

```
call tgsja(a, b, tola, tolb, k, l [,u] [,v] [,q] [,jobu] [,jobv] [,jobq]
[,alpha] [,beta] [,ncycle] [,info])
```

Description

This routine computes the generalized singular value decomposition (GSVD) of two real/complex upper triangular (or trapezoidal) matrices A and B . On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine [?ggsvp](#) from a general m -by- n matrix A and p -by- n matrix B :

$$A = \begin{matrix} & n-k-l & k & l \\ & k & & \\ & l & & \\ m-k-l & & & \end{matrix} \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix}, \quad \text{if } m-k-l \geq 0$$

$$= \begin{matrix} n-k-1 & k & 1 \\ m-k \end{matrix} \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \end{pmatrix}, \quad \text{if } m-k-1 < 0$$

$$B = \begin{matrix} n-k-1 & k & 1 \\ p-1 \end{matrix} \begin{pmatrix} 0 & 0 & B_{13} \\ 0 & 0 & 0 \end{pmatrix}$$

where the k -by- k matrix A_{12} and 1 -by- 1 matrix B_{13} are nonsingular upper triangular; A_{23} is 1 -by- 1 upper triangular if $m-k-1 \geq 0$, otherwise A_{23} is $(m-k)$ -by- 1 upper trapezoidal.

On exit,

$$U^H A Q = D_1^* (0 \ R), \quad V^H B Q = D_2^* (0 \ R),$$

where U , V and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 and D_2 are "diagonal" matrices, which are of the following structures:

If $m-k-1 \geq 0$,

$$D_1 = \begin{matrix} & k & 1 \\ & k & 1 \\ m-k-1 \end{matrix} \begin{pmatrix} 0 & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix}$$

$$D_1 = \begin{matrix} & k & l \\ & l & \\ p-l & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} & n-k-l & k & l \\ k & \begin{pmatrix} 0 & R_{11} & R_{12} \\ 0 & 0 & R_{22} \end{pmatrix} \\ l & \end{matrix}$$

where

$C = \text{diag}(\alpha(k+1), \dots, \alpha(k+l))$

$S = \text{diag}(\beta(k+1), \dots, \beta(k+l))$

$C^2 + S^2 = I$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-l < 0$,

$$D_1 = \begin{matrix} & k & m-l & k+l-m \\ & k & \\ m-k & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \begin{pmatrix} 0 & S & 0 \end{pmatrix} \\ k+1-m & \begin{pmatrix} 0 & 0 & I \end{pmatrix} \\ p-l & \begin{pmatrix} 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} & n-k-l & k & m-k & k+l-m \\ k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \end{pmatrix} \\ m-k & \begin{pmatrix} 0 & 0 & R_{22} & R_{23} \end{pmatrix} \\ k+l-m & \begin{pmatrix} 0 & 0 & 0 & R_{33} \end{pmatrix} \end{matrix}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(m)),$

$S = \text{diag}(\beta(K+1), \dots, \beta(m)),$

$C^2 + S^2 = I$

$$\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \end{pmatrix}$$

On exit, $\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \end{pmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored

in $b(m-k+1:l, n+m-k-l+1:n)$.

The computation of the orthogonal/unitary transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they *may* be postmultiplied into input matrices U_1 , V_1 , or Q_1 .

Input Parameters

jobu CHARACTER*1. Must be 'U', 'I', or 'N'.

If $jobu = 'U'$, u must contain an orthogonal/unitary matrix U_1 on entry.
 If $jobu = 'I'$, u is initialized to the unit matrix.
 If $jobu = 'N'$, u is not computed.

$jobv$ CHARACTER*1. Must be 'V', 'I', or 'N'.
 If $jobv = 'V'$, v must contain an orthogonal/unitary matrix V_1 on entry.
 If $jobv = 'I'$, v is initialized to the unit matrix.
 If $jobv = 'N'$, v is not computed.

$jobq$ CHARACTER*1. Must be 'Q', 'I', or 'N'.
 If $jobq = 'Q'$, q must contain an orthogonal/unitary matrix Q_1 on entry.
 If $jobq = 'I'$, q is initialized to the unit matrix.
 If $jobq = 'N'$, q is not computed.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

p INTEGER. The number of rows of the matrix B ($p \geq 0$).

n INTEGER. The number of columns of the matrices A and B ($n \geq 0$).

k, l INTEGER. Specify the subblocks in the input matrices A and B , whose GSVD is computed.

$a, b, u, v, q, work$ REAL for stgsja
 DOUBLE PRECISION for dtgsja
 COMPLEX for ctgsja
 DOUBLE COMPLEX for ztgsja.

Arrays:
 $a(lda,*)$ contains the m -by- n matrix A .
 The second dimension of a must be at least $\max(1, n)$.
 $b(l db,*)$ contains the p -by- n matrix B .
 The second dimension of b must be at least $\max(1, n)$.
 If $jobu = 'U'$, $u(ldu,*)$ must contain a matrix U_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).
 The second dimension of u must be at least $\max(1, m)$.
 If $jobv = 'V'$, $v(ldv,*)$ must contain a matrix V_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).
 The second dimension of v must be at least $\max(1, p)$.

If $jobq = 'Q'$, $q(ldq,*)$ must contain a matrix Q_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).
The second dimension of q must be at least $\max(1, n)$.
 $work(*)$ is a workspace array.
The dimension of $work$ must be at least $\max(1, 2n)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

ldb INTEGER. The first dimension of b ; at least $\max(1, p)$.

ldu INTEGER. The first dimension of the array u .
 $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise.

ldv INTEGER. The first dimension of the array v .
 $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise.

ldq INTEGER. The first dimension of the array q .
 $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise.

*tola, tol**b* REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.
tola and *tolb* are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in ?ggsvp:
 $tola = \max(m, n) * |A| * \text{MACHEPS}$,
 $tolb = \max(p, n) * |B| * \text{MACHEPS}$.

Output Parameters

a On exit, $a(n-k+1:n, 1:\min(k+1, m))$ contains the triangular matrix R or part of R .

b On exit, if necessary, $b(m-k+1: l, n+m-k-l+1: n)$ contains a part of R .

alpha, beta REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.
Arrays, DIMENSION at least $\max(1, n)$. Contain the generalized singular value pairs of A and B :
 $alpha(1:k) = 1$,
 $beta(1:k) = 0$,
and if $m-k-l \geq 0$,
 $alpha(k+1:k+l) = \text{diag}(C)$,

```

      beta(k+1:k+1) = diag(S),
      or if  $m-k-1 < 0$ ,
      alpha(k+1:m) = C, alpha(m+1:k+1)=0
      beta(K+1:M) = S,
      beta(m+1:k+1) = 1.
      Furthermore, if  $k+1 < n$ ,
      alpha(k+1+1:n) = 0 and
      beta(k+1+1:n) = 0.

u      If jobu = 'I', u contains the orthogonal/unitary matrix U.
      If jobu = 'U', u contains the product  $U_1 * U$ .
      If jobu = 'N', u is not referenced.

v      If jobv = 'I', v contains the orthogonal/unitary matrix U.
      If jobv = 'V', v contains the product  $V_1 * V$ .
      If jobv = 'N', v is not referenced.

q      If jobq = 'I', q contains the orthogonal/unitary matrix U.
      If jobq = 'Q', q contains the product  $Q_1 * Q$ .
      If jobq = 'N', q is not referenced.

ncycle INTEGER. The number of cycles required for convergence.
info    INTEGER.
      If info = 0, the execution is successful.
      If info = -i, the i-th parameter had an illegal value.
      If info = 1, the procedure does not converge after MAXIT
      cycles.

```

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsgja` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (p, n) .
<i>u</i>	Holds the matrix <i>U</i> of size (m, m) .
<i>v</i>	Holds the matrix <i>V</i> of size (p, p) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>alpha</i>	Holds the vector of length (n) .

<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>jobu</i>	If omitted, this argument is restored based on the presence of argument <i>u</i> as follows: <i>jobu</i> = 'U', if <i>u</i> is present, <i>jobu</i> = 'N', if <i>u</i> is omitted. If present, <i>jobu</i> must be equal to 'I' or 'U' and the argument <i>u</i> must also be present. Note that there will be an error condition if <i>jobu</i> is present and <i>u</i> omitted.
<i>jobv</i>	If omitted, this argument is restored based on the presence of argument <i>v</i> as follows: <i>jobv</i> = 'V', if <i>v</i> is present, <i>jobv</i> = 'N', if <i>v</i> is omitted. If present, <i>jobv</i> must be equal to 'I' or 'V' and the argument <i>v</i> must also be present. Note that there will be an error condition if <i>jobv</i> is present and <i>v</i> omitted.
<i>jobq</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>jobq</i> = 'Q', if <i>q</i> is present, <i>jobq</i> = 'N', if <i>q</i> is omitted. If present, <i>jobq</i> must be equal to 'I' or 'Q' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>jobq</i> is present and <i>q</i> omitted.

Driver Routines

Each of the LAPACK driver routines solves a complete problem. To arrive at the solution, driver routines typically call a sequence of appropriate [computational routines](#).

Driver routines are described in the following sections :

[Linear Least Squares \(LLS\) Problems](#)

[Generalized LLS Problems](#)

[Symmetric Eigenproblems](#)

[Nonsymmetric Eigenproblems](#)

- Singular Value Decomposition
- Generalized Symmetric Definite Eigenproblems
- Generalized Nonsymmetric Eigenproblems

Linear Least Squares (LLS) Problems

This section describes LAPACK driver routines used for solving linear least squares problems. Table 4-8 lists all such routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-8 Driver Routines for Solving LLS Problems

Routine Name	Operation performed
?gels	Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.
?gelsy	Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.
?gelss	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.
?gelsd	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

?gels

Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.

Syntax

FORTRAN 77:

```
call sgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call dgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call cgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call zgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
```

Fortran 95:

```
call gels(a, b [,trans] [,info])
```

Description

This routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix A , or its transpose/ conjugate-transpose, using a QR or LQ factorization of A . It is assumed that A has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

```
minimize ||b - A*x||2
```

2. If $trans = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $A*X = B$.

3. If $trans = 'T'$ or $'C'$ and $m \geq n$: find the minimum norm solution of an undetermined system $A_H^*X = B$.

4. If $trans = 'T'$ or $'C'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

```
minimize ||b - AH*x||2
```

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- nrh solution matrix X .

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N', 'T', or 'C'. If $trans = 'N'$, the linear system involves matrix A ; If $trans = 'T'$, the linear system involves the transposed matrix A^T (for real flavors only); If $trans = 'C'$, the linear system involves the conjugate-transposed matrix A^H (for complex flavors only).
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).

<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for <i>sgels</i> DOUBLE PRECISION for <i>dgels</i> COMPLEX for <i>cgels</i> DOUBLE COMPLEX for <i>zgels</i> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the matrix <i>B</i> of right hand side vectors, stored columnwise; <i>B</i> is <i>m</i> -by- <i>nrhs</i> if <i>trans</i> = 'N' , or <i>n</i> -by- <i>nrhs</i> if <i>trans</i> = 'T' or 'C'. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; must be at least $\min(m, n) + \max(1, m, n, nrhs)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	On exit, overwritten by the factorization data as follows: if $m \geq n$, array <i>a</i> contains the details of the <i>QR</i> factorization of the matrix <i>A</i> as returned by ?geqrf ; if $m < n$, array <i>a</i> contains the details of the <i>LQ</i> factorization of the matrix <i>A</i> as returned by ?gelqf .
<i>b</i>	If <i>info</i> = 0, <i>b</i> overwritten by the solution vectors, stored columnwise:

if *trans* = 'N' and $m \geq n$, rows 1 to n of *b* contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $n+1$ to m in that column;
 if *trans* = 'N' and $m < n$, rows 1 to n of *b* contain the minimum norm solution vectors;
 if *trans* = 'T' or 'C' and $m \geq n$, rows 1 to m of *b* contain the minimum norm solution vectors; if *trans* = 'T' or 'C' and $m < n$, rows 1 to m of *b* contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $m+1$ to n in that column.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of the triangular factor of *A* is zero, so that *A* does not have full rank; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gels* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>b</i>	Holds the matrix of size $\max(m, n)$ -by- <i>nrhs</i> . If <i>trans</i> = 'N', then, on entry, the size of <i>b</i> is m -by- <i>nrhs</i> , If <i>trans</i> = 'T', then, on entry, the size of <i>b</i> is n -by- <i>nrhs</i> ,
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = \min(m, n) + \max(1, m, n, nrhs) * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.

Syntax

FORTRAN 77:

```
call sgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call dgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call cgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork,
info)
call zgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork,
info)
```

Fortran 95:

```
call gelsy(a, b [,rank] [,jpvt] [,rcond] [,info])
```

Description

This routine computes the minimum-norm solution to a real/complex linear least squares problem:

$$\text{minimize } ||b - A*x||_2$$

using a complete orthogonal factorization of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The routine first computes a QR factorization with column pivoting:

$$AP = Q \begin{pmatrix} R_{11} & R_{12} \\ 0 & R_{22} \end{pmatrix}$$

with R_{11} defined as the largest leading submatrix whose estimated condition number is less than $1/rcond$. The order of R_{11} , $rank$, is the effective rank of A . Then, R_{22} is considered to be negligible, and R_{12} is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

$$AP = Q \begin{pmatrix} T_{11} & 0 \\ 0 & 0 \end{pmatrix} Z$$

The minimum-norm solution is then

$$X = PZ^H \begin{pmatrix} T_{11}^{-1} & Q_1^H b \\ 0 & 0 \end{pmatrix}$$

where Q_1 consists of the first $rank$ columns of Q . This routine is basically identical to the original `qelsx` except three differences:

- The call to the subroutine `?geqpf` has been substituted by the call to the subroutine `?geqp3`. This subroutine is a BLAS-3 version of the QR factorization with column pivoting.
- Matrix B (the right hand side) is updated with BLAS-3.
- The permutation of matrix B (the right hand side) is faster and more simple.

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
$a, b, work$	REAL for <code>sgelsy</code> DOUBLE PRECISION for <code>dgelsy</code> COMPLEX for <code>cgelsy</code> DOUBLE COMPLEX for <code>zgelsy</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the m -by- $nrhs$ right hand side matrix B . The second dimension of b must be at least $\max(1, nrhs)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The first dimension of b ; must be at least $\max(1, m, n)$.
$jpvt$	INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if $jpvt(i) \neq 0$, the i -th column of A is permuted to the front of AP , otherwise the i -th column of A is a free column.
$rcond$	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

rcond is used to determine the effective rank of A , which is defined as the order of the largest leading triangular submatrix R_{11} in the QR factorization with pivoting of A , whose estimated condition number $< 1/rcond$.

lwork

INTEGER. The size of the *work* array.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

rwork

REAL for [cgelsy](#) DOUBLE PRECISION for [zgelsy](#).

Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

a

On exit, overwritten by the details of the complete orthogonal factorization of A .

b

Overwritten by the n -by-*nrhs* solution matrix X .

jpvt

On exit, if *jpvt*(*i*) = *k*, then the *i*-th column of AP was the *k*-th column of A .

rank

INTEGER. The effective rank of A , that is, the order of the submatrix R_{11} . This is the same as the order of the submatrix T_{11} in the complete orthogonal factorization of A .

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine [gelsy](#) interface are the following:

a

Holds the matrix A of size (m, n) .

<i>b</i>	Holds the matrix of size $\max(m, n)$ -by- <i>nrhs</i> . On entry, contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>jpvt</i>	Holds the vector of length (<i>n</i>). Default value for this element is <i>jpvt</i> (<i>i</i>) = 0.
<i>rcond</i>	Default value for this element is <i>rcond</i> = 100*EPSILON(1.0_WP).

Application Notes

For real flavors:

The unblocked strategy requires that:

$$lwork \geq \max(mn+3n+1, 2*mn + nrhs),$$

where $mn = \min(m, n)$.

The block algorithm requires that:

$$lwork \geq \max(mn+2n+nb*(n+1), 2*mn+nb*nrhs),$$

where *nb* is an upper bound on the blocksize returned by [ilaenv](#) for the routines [sgeqp3/dgeqp3](#), [stzrzf/dtzrzf](#), [stzrqf/dtzrqf](#), [sormqr/dormqr](#), and [sormrz/dormrz](#).

For complex flavors:

The unblocked strategy requires that:

$$lwork \geq mn + \max(2*mn, n+1, mn + nrhs),$$

where $mn = \min(m, n)$.

The block algorithm requires that:

$$lwork < mn + \max(2*mn, nb*(n+1), mn+mn*nb, mn+ nb*nrhs),$$

where *nb* is an upper bound on the blocksize returned by [ilaenv](#) for the routines [cgeqp3/zgeqp3](#), [ctzrzf/ztzrzf](#), [ctzrqf/ztzrqf](#), [cunmqr/zunmqr](#), and [cunmrz/zunmrz](#).

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelss

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A .

Syntax

FORTRAN 77:

```
call sgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call dgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call cgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork,
info)
call zgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork,
info)
```

Fortran 95:

```
call gelss(a, b [,rank] [,s] [,rcond] [,info])
```

Description

This routine computes the minimum norm solution to a real linear least squares problem:

minimize $\|b - A \cdot x\|_2$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X . The effective rank of A is determined by treating as zero those singular values which are less than `rcond` times the largest singular value.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for <i>sgelss</i> DOUBLE PRECISION for <i>dgelss</i> COMPLEX for <i>cgelss</i> DOUBLE COMPLEX for <i>zgelss</i> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>rcond</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>rcond</i> is used to determine the effective rank of <i>A</i> . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If <i>rcond</i> < 0, machine precision is used instead.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for <i>cgelss</i> DOUBLE PRECISION for <i>zgelss</i> .

Workspace array used in complex flavors only. `DIMENSION` at least $\max(1, 5 * \min(m, n))$.

Output Parameters

<i>a</i>	On exit, the first $\min(m, n)$ rows of <i>A</i> are overwritten with its right singular vectors, stored row-wise.
<i>b</i>	Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> . If $m \geq n$ and <i>rank</i> = <i>n</i> , the residual sum-of-squares for the solution in the <i>i</i> -th column is given by the sum of squares of modulus of elements <i>n</i> +1: <i>m</i> in that column.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, <code>DIMENSION</code> at least $\max(1, \min(m, n))$. The singular values of <i>A</i> in decreasing order. The condition number of <i>A</i> in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$.
<i>rank</i>	INTEGER. The effective rank of <i>A</i> , that is, the number of singular values which are greater than <i>rcond</i> * <i>s</i> (1).
<i>work</i> (1)	If <i>info</i> = 0, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm for computing the SVD failed to converge; <i>i</i> indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelss` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .

<i>b</i>	Holds the matrix of size $\max(m, n)$ -by- <i>nrhs</i> . On entry, contains the m -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the n -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>s</i>	Holds the vector of length $\min(m, n)$.
<i>rcond</i>	Default value for this element is <i>rcond</i> = 100*EPSILON(1.0_WP).

Application Notes

For real flavors:

$$lwork \geq 3 * \min(m, n) + \max(2 * \min(m, n), \max(m, n), nrhs)$$

For complex flavors:

$$lwork \geq 2 * \min(m, n) + \max(m, n, nrhs)$$

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsd

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

Syntax

FORTRAN 77:

```
call sgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork,
info)

call dgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork,
info)

call cgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork,
iwork, info)

call zgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork,
iwork, info)
```

Fortran 95:

```
call gelsd(a, b [,rank] [,s] [,rcond] [,info])
```

Description

This routine computes the minimum-norm solution to a real linear least squares problem:

minimize $\|b - A^*x\|_2$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The problem is solved in three steps:

1. Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).
2. Solve the BLS using a divide and conquer approach.
3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

The routine uses auxiliary routines `?lals0` and `?lalsa`.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a, b, work</i>	REAL for <code>sgelsd</code> DOUBLE PRECISION for <code>dgelsd</code> COMPLEX for <code>cgelsd</code> DOUBLE COMPLEX for <code>zgelsd</code>. Arrays: <i>a</i>(<i>lda</i>,*) contains the m-by-n matrix A. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i>(<i>ldb</i>,*) contains the m-by-<i>nrhs</i> right hand side matrix B. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>rcond</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>rcond</i> is used to determine the effective rank of A. Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If <i>rcond</i> ≤ 0, machine precision is used instead.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq 1$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the array <i>work</i> and the minimum sizes of the arrays <i>rwork</i> and <i>iwork</i>, and

returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* is issued by [xerbla](#).

See *Application Notes* for the suggested value of *lwork*.

iwork INTEGER. Workspace array. See *Application Notes* for the suggested dimension of *iwork*.

rwork REAL for `cgelsd`
DOUBLE PRECISION for `zgelsd`.
Workspace array, used in complex flavors only. See *Application Notes* for the suggested dimension of *rwork*.

Output Parameters

a On exit, *A* has been overwritten.

b Overwritten by the *n*-by-*nrhs* solution matrix *X*.

If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the *i*-th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

s REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, \min(m, n))$. The singular values of *A* in decreasing order. The condition number of *A* in the 2-norm is
 $k^2(A) = s(1) / s(\min(m, n))$.

rank INTEGER. The effective rank of *A*, that is, the number of singular values which are greater than $rcond * s(1)$.

work(1) If *info* = 0, on exit, *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

rwork(1) If *info* = 0, on exit, *rwork*(1) returns the minimum size of the workspace array *iwork* required for optimum performance.

iwork(1) If *info* = 0, on exit, *iwork*(1) returns the minimum size of the workspace array *iwork* required for optimum performance.

info INTEGER.

If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, then the algorithm for computing the SVD failed to converge; i indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelsd` interface are the following:

a	Holds the matrix A of size (m, n) .
b	Holds the matrix of size $\max(m, n)$ -by- $nrhs$. On entry, contains the m -by- $nrhs$ right hand side matrix B , On exit, overwritten by the n -by- $nrhs$ solution matrix X .
s	Holds the vector of length $\min(m, n)$.
$rcond$	Default value for this element is $rcond = 100 * \text{EPSILON}(1.0\_WP)$.

Application Notes

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

The exact minimum amount of workspace needed depends on m , n and $nrhs$. The size $lwork$ of the workspace array `work` must be as given below.

For real flavors:

If $m \geq n$,

$$lwork \geq 12n + 2n * smlsiz + 8n * nlvl + n * nrhs + (smlsiz + 1)^2;$$

If $m < n$,

$$lwork \geq 12m + 2m * smlsiz + 8m * nlvl + m * nrhs + (smlsiz + 1)^2;$$

For complex flavors:

If $m \geq n$,

$lwork < 2n + n*nrhs;$

If $m < n$,

$lwork \geq 2m + m*nrhs;$

where *smlsiz* is returned by *ilaenv* and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and

$nlvl = \text{INT}(\log_2(\min(m, n)/(smlsiz+1))) + 1.$

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The dimension of the workspace array *iwork* must be at least

$3*\min(m, n)*nlvl + 11*\min(m, n).$

The dimension of the workspace array *iwork* (for complex flavors) must be at least $\max(1, lrwork).$

$lrwork \geq 10n + 2n*smlsiz + 8n*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2$ if $m \geq n$, and

$lrwork \geq 10m + 2m*smlsiz + 8m*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2$ if $m < n$.

Generalized LLS Problems

This section describes LAPACK driver routines used for solving generalized linear least squares problems. [Table 4-9](#) lists all such routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-9 Driver Routines for Solving Generalized LLS Problems

Routine Name	Operation performed
?gglse	Solves the linear equality-constrained least squares problem using a generalized RQ factorization.
?ggglm	Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

?gglse

Solves the linear equality-constrained least squares problem using a generalized RQ factorization.

Syntax

FORTRAN 77:

```
call sgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call dgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call cgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call zgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
```

Fortran 95:

```
call gglse(a, b, c, d, x [,info])
```

Description

This routine solves the linear equality-constrained least squares (LSE) problem:

minimize $||c - A*x||^2$ subject to $B*x = d$

where A is an m -by- n matrix, B is a p -by- n matrix, c is a given m -vector, and d is a given p -vector. It is assumed that $p \leq n \leq m+p$, and

$$\text{rank}(B)=p \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = n .$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

$$B = (0 \ R)^T Q, \quad A = Z^T T^T Q$$

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
p	INTEGER. The number of rows of the matrix B ($0 \leq p \leq n \leq m+p$).
$a, b, c, d, work$	REAL for sgglse DOUBLE PRECISION for dgglse COMPLEX for cgglse DOUBLE COMPLEX for zgglse. Arrays: $a(lda,*)$ contains the m-by-n matrix A. The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the p-by-n matrix B. The second dimension of b must be at least $\max(1, n)$. $c(*)$, dimension at least $\max(1, m)$, contains the right hand side vector for the least squares part of the LSE problem. $d(*)$, dimension at least $\max(1, p)$, contains the right hand side vector for the constrained equation. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The first dimension of b ; at least $\max(1, p)$.
$lwork$	INTEGER. The size of the $work$ array; $lwork \geq \max(1, m+n+p)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla. See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

<i>x</i>	REAL for <i>sggls</i> DOUBLE PRECISION for <i>dggls</i> COMPLEX for <i>cggls</i> DOUBLE COMPLEX for <i>zggls</i>. Array, DIMENSION at least $\max(1, n)$. On exit, contains the solution of the LSE problem.
<i>a</i>	On exit, the elements on and above the diagonal of the array contain the $\min(m, n)$-by-n upper trapezoidal matrix T.
<i>b</i>	On exit, the upper triangle of the subarray $b(1:p, n-p+1:n)$ contains the p-by-p upper triangular matrix R.
<i>d</i>	On exit, <i>d</i> is destroyed.
<i>c</i>	On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements $n-p+1$ to m of vector <i>c</i>.
<i>work</i> (1)	If <i>info</i> = 0, on exit, <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = 1, the upper triangular factor R associated with B in the generalized RQ factorization of the pair (B, A) is singular, so that $\text{rank}(B) < P$; the least squares solution could not be computed. If <i>info</i> = 2, the $(n-p)$-by-$(n-p)$ part of the upper trapezoidal factor T associated with A in the generalized RQ factorization of the pair (B, A) is singular, so that

$$\text{rank} \begin{pmatrix} A \\ B \end{pmatrix} < n$$

; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gglse` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (p, n) .
<i>c</i>	Holds the vector of length (m) .
<i>d</i>	Holds the vector of length (p) .
<i>x</i>	Holds the vector of length (n) .

Application Notes

For optimum performance, use

$$lwork \geq p + \min(m, n) + \max(m, n) * nb,$$

where *nb* is an upper bound for the optimal blocksizes for `?geqrf`, `?gerqf`, `?ormqr`/`?unmqr` and `?ormrq`/`?unmrq`.

You may set *lwork* to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggglm

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

Syntax

FORTRAN 77:

```
call sggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call dggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call cggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call zggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
```

Fortran 95:

```
call ggglm(a, b, d, x, y [,info])
```

Description

This routine solves a general Gauss-Markov linear model (GLM) problem:

minimize_x ||y||₂ subject to $d = A^*x + B^*y$

where A is an n -by- m matrix, B is an n -by- p matrix, and d is a given n -vector. It is assumed that $m \leq n \leq m+p$, and $\text{rank}(A) = m$ and $\text{rank}(A \ B) = n$.

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y , which is obtained using a generalized QR factorization of the matrices $(A, \ B)$ given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix}; \quad B = Q^* T^* Z.$$

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

minimize_x || $B^{-1}(d - A^*x)$ ||₂.

Input Parameters

<i>n</i>	INTEGER. The number of rows of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>m</i>	INTEGER. The number of columns in <i>A</i> ($m \geq 0$).
<i>p</i>	INTEGER. The number of columns in <i>B</i> ($p \geq n - m$).
<i>a, b, d, work</i>	REAL for sggglm DOUBLE PRECISION for dggglm COMPLEX for cggglm DOUBLE COMPLEX for zggglm. Arrays: <i>a(lda,*)</i> contains the <i>n</i> -by- <i>m</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, m)$. <i>b(l db,*)</i> contains the <i>n</i> -by- <i>p</i> matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, p)$. <i>d(*)</i> , dimension at least $\max(1, n)$, contains the left hand side of the GLM equation. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq \max(1, n+m+p)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>x, y</i>	REAL for sggglm DOUBLE PRECISION for dggglm COMPLEX for cggglm DOUBLE COMPLEX for zggglm. Arrays <i>x</i> (*), <i>y</i> (*). DIMENSION at least $\max(1, m)$ for <i>x</i> and at least $\max(1, p)$ for <i>y</i> .

	On exit, x and y are the solutions of the GLM problem.
a	On exit, the upper triangular part of the array a contains the m -by- m upper triangular matrix R .
b	On exit, if $n \leq p$, the upper triangle of the subarray $b(1:n, p-n+1:p)$ contains the n -by- n upper triangular matrix T ; if $n > p$, the elements on and above the $(n-p)$ -th subdiagonal contain the n -by- p upper trapezoidal matrix T .
d	On exit, d is destroyed
$work(1)$	If $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that $rank(A) < m$; the least squares solution could not be computed. If $info = 2$, the bottom $(n-m)$ -by- $(n-m)$ part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that $rank(A, B) < n$; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggglm` interface are the following:

a	Holds the matrix A of size (n, m) .
b	Holds the matrix B of size (n, p) .
d	Holds the vector of length (n) .
x	Holds the vector of length (m) .
y	Holds the vector of length (p) .

Application Notes

For optimum performance, use

$$lwork \geq m + \min(n, p) + \max(n, p)*nb,$$

where *nb* is an upper bound for the optimal blocksizes for `?geqrf`, `?gerqf`, `?ormqr`/`?unmqr` and `?ormrq`/`?unmrq`.

You may set *lwork* to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Symmetric Eigenproblems

This section describes LAPACK driver routines used for solving symmetric eigenvalue problems. See also computational routines [computational routines](#) that can be called to solve these problems. [Table 4-10](#) lists all such driver routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-10 Driver Routines for Solving Symmetric Eigenproblems

Routine Name	Operation performed
?syev / ?heev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix.
?syevd / ?heevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix using divide and conquer algorithm.
?syevx / ?heevx	Computes selected eigenvalues and, optionally, eigenvectors of a symmetric / Hermitian matrix.
?syevr / ?heevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix using the Relatively Robust Representations.
?spev / ?hpev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.

Routine Name	Operation performed
?spevd / ?hpevd	Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix held in packed storage.
?spevx / ?hpevx	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
?sbev / ?hbev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
?sbevd / ?hbevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian band matrix using divide and conquer algorithm.
?sbevz / ?hbevz	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
?stev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.
?stevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.
?stevx	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
?stevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

[?syev](#)

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyev(jobz, uplo, n, a, lda, w, work, lwork, info)
call dsyev(jobz, uplo, n, a, lda, w, work, lwork, info)
```

Fortran 95:

```
call syev(a, w [,jobz] [,uplo] [,info])
```

Description

This routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A .

Note that for most cases of real symmetric eigenvalue problems the default choice should be [?syevr](#) function as its underlying algorithm is faster and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	REAL for <code>ssyev</code> DOUBLE PRECISION for <code>dsyev</code> Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraint: $lwork \geq \max(1, 3n-1)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla .

See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix <i>A</i> . If <i>jobz</i> = 'N', then on exit the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	REAL for ssyev DOUBLE PRECISION for dsyev Array, DIMENSION at least max(1, <i>n</i>). If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order.
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syev* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>job</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance set $lwork \geq (nb+2) * n$, where *nb* is the blocksize for ?sytrd returned by ilaenv.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

If `lwork` has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array `work`. This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

cheev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
call zheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
```

Fortran 95:

```
call heev(a, w [,jobz] [,uplo] [,info])
```

Description

This routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A .

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be [?heevr](#) function as its underlying algorithm is faster and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	COMPLEX for cheev DOUBLE COMPLEX for zheev Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . C onstraint: $lwork \geq \max(1, 2n-1)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla .

rwork See *Application Notes* for the suggested value of *lwork*.
 REAL for cheev
 DOUBLE PRECISION for zheev.
 Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, array *a* contains the orthonormal eigenvectors of the matrix *A*.
 If *jobz* = 'N', then on exit the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

w REAL for cheev
 DOUBLE PRECISION for zheev
 Array, DIMENSION at least $\max(1, n)$.
 If *info* = 0, contains the eigenvalues of the matrix *A* in ascending order.

work(1) On exit, if *lwork* > 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *heev* interface are the following:

a Holds the matrix *A* of size (*n*, *n*).
w Holds the vector of length (*n*).
job Must be 'N' or 'V'. The default value is 'N'.
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use

$$lwork \geq (nb+1) * n,$$

where nb is the blocksize for `?hetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?syevd

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call ssyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
call dsyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call syevd(a, w [,jobz] [,uplo] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A . In other words, it can compute the spectral factorization of A as: $A = Z \Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A * z_i = \lambda_i * z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be `?syevr` function as its underlying algorithm is faster and uses less workspace. `?syevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	REAL for <code>ssyevd</code> DOUBLE PRECISION for <code>dsyevd</code> Array, DIMENSION (<i>lda</i>, *). <i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i>. Must be at least $\max(1, n)$.
<i>work</i>	REAL for <code>ssyevd</code> DOUBLE PRECISION for <code>dsyevd</code>. Workspace array, DIMENSION at least <i>lwork</i>.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints:

if $n \leq 1$, then $lwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $lwork \geq 2*n + 1$;
 if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n^2 + 6*n + 1$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, its dimension $\max(1, liwork)$.*liwork*

INTEGER.

The dimension of the array *iwork*.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n + 3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w

REAL for ssyevd

DOUBLE PRECISION for dsyevd

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix *A* in ascending order. See also *info*.

a

If $jobz = 'V'$, then on exit this array is overwritten by the orthogonal matrix *Z* which contains the eigenvectors of *A*.

work(1)

On exit, if $lwork > 0$, then *work*(1) returns the required minimal size of *lwork*.

<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i>, then the algorithm failed to converge; <i>i</i> indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero. If <i>info</i> = <i>i</i>, and <i>jobz</i> = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>info</i>/(<i>n</i>+1) through <i>mod</i>(<i>info</i>,<i>n</i>+1). If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syevd* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [?heevd](#)

?heevd

Computes all eigenvalues and (optionally) all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

Syntax

FORTTRAN 77:

```
call cheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork,
liwork, info)

call zheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork,
liwork, info)
```

Fortran 95:

```
call heevd(a, w [,job] [,uplo] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A . In other words, it can compute the spectral factorization of A as: $A = Z \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of complex Hermetian eigenvalue problems the default choice should be `?heevr` function as its underlying algorithm is faster and uses less workspace. `?heevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	COMPLEX for <code>cheevd</code> DOUBLE COMPLEX for <code>zheevd</code> Array, DIMENSION (<i>lda</i>, *). <i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>work</i>	COMPLEX for <code>cheevd</code> DOUBLE COMPLEX for <code>zheevd</code>. Workspace array, DIMENSION $\max(1, lwork)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints: if $n \leq 1$, then $lwork \geq 1$; if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq n+1$; if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq n^2+2*n$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries

of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork REAL for cheevd
DOUBLE PRECISION for zheevd
Workspace array, DIMENSION at least *lrwork*.

lrwork INTEGER.
The dimension of the array *rwork*. Constraints:
if $n \leq 1$, then $lrwork \geq 1$;
if $job = 'N'$ and $n > 1$, then $lrwork \geq n$;
if $job = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.
If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*. Constraints: if $n \leq 1$, then $liwork \geq 1$;
if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.
If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w REAL for cheevd
DOUBLE PRECISION for zheevd
Array, DIMENSION at least $\max(1, n)$.

	If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i> .
<i>a</i>	If <i>jobz</i> = 'V', then on exit this array is overwritten by the unitary matrix <i>Z</i> which contains the eigenvectors of <i>A</i> .
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then the real part of <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>lrwork</i> > 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i> , and <i>jobz</i> = 'N', then the algorithm failed to converge; <i>i</i> off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if <i>info</i> = <i>i</i> , and <i>jobz</i> = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>info</i> /(<i>n</i> +1) through mod(<i>info</i> , <i>n</i> +1). If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevd` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of `lwork` (`liwork` or `lrwork`) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible `lwork` (`liwork` or `lrwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [?syevd](#). See also [?hpevd](#) for matrices held in packed storage, and [?hbevd](#) for banded matrices.

?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, work, lwork, iwork, ifail, info)
```

```
call dsyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, work, lwork, iwork, ifail, info)
```

Fortran 95:

```
call syevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be `?syevr` function as its underlying algorithm is faster and uses less workspace. `?syevx` is faster for a few selected eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval (<i>vl</i>, <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i> , <i>work</i>	REAL for <code>ssyevx</code> DOUBLE PRECISION for <code>dsyevx</code>. Arrays: <i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i>. Must be at least $\max(1, n)$.
<i>vl</i> , <i>vu</i>	REAL for <code>ssyevx</code> DOUBLE PRECISION for <code>dsyevx</code>. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i> , <i>iu</i>	INTEGER.

If $range = 'I'$, the indices of the smallest and largest eigenvalues to be returned.

Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$;

$il = 1$ and $iu = 0$, if $n = 0$.

Not referenced if $range = 'A'$ or $'V'$.

abstol

REAL for `ssyevx`

DOUBLE PRECISION for `dsyevx`.

The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz

INTEGER. The first dimension of the output array *z*; $ldz \geq 1$.

If $jobz = 'V'$, then $ldz \geq \max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

If $n \leq 1$ then $lwork \geq 1$, otherwise $lwork = 8 * n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.

See *Application Notes* for the suggested value of *lwork*.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of *A*, including the diagonal, is overwritten.

m

INTEGER. The total number of eigenvalues found;

$0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$.

w

REAL for `ssyevx`

DOUBLE PRECISION for `dsyevx`

Array, DIMENSION at least $\max(1, n)$. The first *m* elements contain the selected eigenvalues of the matrix *A* in ascending order.

<i>z</i>	REAL for <i>ssyevx</i> DOUBLE PRECISION for <i>dsyevx</i>. Array <i>z(ldz,*)</i> contains eigenvectors. The second dimension of <i>z</i> must be at least $\max(1, m)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>z</i> holding the eigenvector associated with <i>w(i)</i>. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i>; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>work(1)</i>	On exit, if <i>lwork</i> > 0, then <i>work(1)</i> returns the required minimal size of <i>lwork</i>.
<i>ifail</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> elements of <i>ifail</i> are zero; if <i>info</i> > 0, then <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'V', then <i>ifail</i> is not referenced.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = <i>i</i>, then <i>i</i> eigenvectors failed to converge; their indices are stored in the array <i>ifail</i>.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syevx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .

<i>w</i>	Holds the vector of length (<i>n</i>).
<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>ifail</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+3)*n$, where *nb* is the maximum of the blocksize for ?sytrd and ?ormtr returned by ilaenv.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If *lwork* has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array *work*. This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * |T|$ is used as tolerance, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{slamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * \text{slamch}('S')$.

?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, work, lwork, rwork, iwork, ifail, info)

call zheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, work, lwork, rwork, iwork, ifail, info)
```

Fortran 95:

```
call heevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of complex Hermetian eigenvalue problems the default choice should be [?heevr](#) function as its underlying algorithm is faster and uses less workspace. [?heevx](#) is faster for a few selected eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

range CHARACTER*1. Must be 'A', 'V', or 'I'.
 If *range* = 'A', all eigenvalues will be found.
 If *range* = 'V', all eigenvalues in the half-open interval (*vl*, *vu*] will be found.
 If *range* = 'I', the eigenvalues with indices *il* through *iu* will be found.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *a* stores the upper triangular part of *A*.
 If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

a, *work* COMPLEX for cheevx
 DOUBLE COMPLEX for zheevx.
 Arrays:
a(*lda*,*) is an array containing either upper or lower triangular part of the Hermitian matrix *A*, as specified by *uplo*.
 The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*. Must be at least $\max(1, n)$.

vl, *vu* REAL for cheevx
 DOUBLE PRECISION for zheevx.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if *range* = 'A' or 'I'.

il, *iu* INTEGER.
 If *range* = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints:
 $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if *range* = 'A' or 'V'.

abstol REAL for cheevx
 DOUBLE PRECISION for zheevx. The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

<i>ldz</i>	INTEGER. The first dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. $lwork \geq 1$ if $n \leq 1$; otherwise at least $2*n$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.
<i>rwork</i>	REAL for cheevx DOUBLE PRECISION for zheevx. Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i>, including the diagonal, is overwritten.
<i>m</i>	INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu-il+1$.
<i>w</i>	REAL for cheevx DOUBLE PRECISION for zheevx Array, DIMENSION at least $\max(1, n)$. The first <i>m</i> elements contain the selected eigenvalues of the matrix <i>A</i> in ascending order.
<i>z</i>	COMPLEX for cheevx DOUBLE COMPLEX for zheevx. Array <i>z</i>(<i>ldz</i>,*) contains eigenvectors. The second dimension of <i>z</i> must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$work(1)$ On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

$ifail$ INTEGER.
Array, DIMENSION at least $\max(1, n)$.
If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, then $ifail$ contains the indices of the eigenvectors that failed to converge.
If $jobz = 'V'$, then $ifail$ is not referenced.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevx` interface are the following:

a	Holds the matrix A of size (n, n) .
w	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$ifail$	Holds the vector of length (n) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.

<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where *nb* is the maximum of the blocksize for ?hetrd and ?unmtr returned by [ilaenv](#).

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If `abstol` is less than or equal to zero, then $\epsilon * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing `A` to tridiagonal form. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold `2*slamch('S')`, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to `2*slamch('S')`.

?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call ssyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, isuppz, work, lwork, iwork, liwork, info)

call dsyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, isuppz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call syevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix `A`. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix `A` to tridiagonal form `T` with a call to [?sytrd](#). Then, whenever possible, [?syevr](#) calls [?stemr](#) to compute the eigenspectrum using Relatively Robust Representations. [?stemr](#) computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various “good” $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the each unreduced block of `T`:

- a.** Compute $T - \sigma^* I = L^* D^* L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?syevr` calls `?stemr` when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. `?syevr` calls `?stebz` and `?stein` on non-IEEE machines and when partial spectrum requests are made.

Note that `?syevr` is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu.$ If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>. For <i>range</i> = 'V' or 'I' and $iu - il < n - 1$, <code>sstebz/dstebz</code> and <code>sstein/dstein</code> are called.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', *a* stores the upper triangular part of *A*.
 If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

a, *work* REAL for ssyevr
 DOUBLE PRECISION for dsyevr.

Arrays:
a(*lda*,*) is an array containing either upper or lower triangular part of the symmetric matrix *A*, as specified by *uplo*.
 The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*. Must be at least $\max(1, n)$.

vl, *vu* REAL for ssyevr
 DOUBLE PRECISION for dsyevr.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, *iu* INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint:
 $1 \leq il \leq iu \leq n$, if $n > 0$;
 $il=1$ and $iu=0$, if $n = 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for ssyevr
 DOUBLE PRECISION for dsyevr. The absolute error tolerance to which each eigenvalue/eigenvector is required.
 If *jobz* = 'V', the eigenvalues and eigenvectors output have residual norms bounded by *abstol*, and the dot products between different eigenvectors are bounded by *abstol*.

If $abstol < n * \epsilon * |T|$, then $n * \epsilon * |T|$ is used instead, where ϵ is the machine precision, and $|T|$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $\epsilon * |T|$ irrespective of $abstol$.
If high relative accuracy is important, set $abstol$ to `?lamch('S')`.

ldz INTEGER. The leading dimension of the output array *z*.
Constraints:

$ldz \geq 1$ if $jobz = 'N'$;
 $ldz < \max(1, n)$ if $jobz = 'V'$.

lwork INTEGER.
The dimension of the array *work*.

Constraint: $lwork \geq \max(1, 26n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
See *Application Notes* for the suggested value of *lwork*.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*, $lwork \geq \max(1, 10n)$.
If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by [xerbla](#).

Output Parameters

a On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

m INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.
If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$.

w, z REAL for `ssyevr`
DOUBLE PRECISION for `dsyevr`.

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in $w(1)$ to $w(m)$;
 $z(ldz, *)$, the second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If $jobz = 'N'$, then z is not referenced. Note that you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

isuppz

INTEGER.

Array, DIMENSION at least $2 * \max(1, m)$.

The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $isuppz(2i-1)$ through $isuppz(2i)$. Referenced only if eigenvectors are needed ($jobz = 'V'$) and all eigenvalues are needed, that is, $range = 'A'$ or $range = 'I'$ and $il = 1$ and $iu = n$.

work(1)

On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

iwork(1)

On exit, if $info = 0$, then *iwork(1)* returns the required minimal size of *liwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevr` interface are the following:

a Holds the matrix *A* of size (n, n) .

<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length ($2*m$), where the values ($2*m$) are significant.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+6)*n$, where *nb* is the maximum of the blocksize for ?sytrd and ?ormtr returned by ilaenv.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if `lwork` (`liwork`) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call cheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)

call zheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call heevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to `?hetrd`. Then, whenever possible, `?heevr` calls `?stegr` to compute the eigenspectrum using Relatively Robust Representations. `?stegr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various “good” L^*D*L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of T :

- a.** Compute $T - \sigma^* I = L^* D^* L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?heevr` calls `?stemr` when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or `?stebz` and `?stein` on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `?heevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $v_l < \lambda(i) \leq v_u$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>. For <i>range</i> = 'V' or 'I', <code>sstebz/dstebz</code> and <code>cstein/zstein</code> are called.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', *a* stores the upper triangular part of *A*.
 If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n
 INTEGER. The order of the matrix *A* ($n \geq 0$).

a, work
 COMPLEX for *cheevr*
 DOUBLE COMPLEX for *zheevr*.
 Arrays:
a(lda,)* is an array containing either upper or lower triangular part of the Hermitian matrix *A*, as specified by *uplo*.
 The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda
 INTEGER. The first dimension of the array *a*.
 Must be at least $\max(1, n)$.

vl, vu
 REAL for *cheevr*
 DOUBLE PRECISION for *zheevr*.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu
 INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol
 REAL for *cheevr*
 DOUBLE PRECISION for *zheevr*.
 The absolute error tolerance to which each eigenvalue/eigenvector is required.
 If *jobz* = 'V', the eigenvalues and eigenvectors output have residual norms bounded by *abstol*, and the dot products between different eigenvectors are bounded by *abstol*.

If $abstol < n * \epsilon * |T|$, then $n * \epsilon * |T|$ will be used in its place, where ϵ is the machine precision, and $|T|$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $\epsilon * |T|$ irrespective of $abstol$. If high relative accuracy is important, set $abstol$ to `?lamch('S')`.

ldz INTEGER. The leading dimension of the output array *z*.
Constraints:

$ldz \geq 1$ if *jobz* = 'N';
 $ldz \geq \max(1, n)$ if *jobz* = 'V'.

lwork INTEGER.
The dimension of the array *work*.

Constraint: $lwork \geq \max(1, 2n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

rwork REAL for cheevr
DOUBLE PRECISION for zheevr.
Workspace array, DIMENSION $\max(1, lwork)$.

lrwork INTEGER.
The dimension of the array *rwork*;
 $lwork \geq \max(1, 24n)$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*,
 $lwork \geq \max(1, 10n)$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu-il+1$.
<i>w</i>	REAL for <i>cheevr</i> DOUBLE PRECISION for <i>zheevr</i> . Array, DIMENSION at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in <i>w</i> (1) to <i>w</i> (<i>m</i>).
<i>z</i>	COMPLEX for <i>cheevr</i> DOUBLE COMPLEX for <i>zheevr</i> . Array <i>z</i> (<i>ldz</i> , *); the second dimension of <i>z</i> must be at least $\max(1, m)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>T</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>isuppz</i>	INTEGER. Array, DIMENSION at least $2 * \max(1, m)$. The support of the eigenvectors in <i>z</i> , i.e., the indices indicating the nonzero elements in <i>z</i> . The <i>i</i> -th eigenvector is nonzero only in elements <i>isuppz</i> (2 <i>i</i> -1) through

	<i>isuppz</i> (2 <i>i</i>). Referenced only if eigenvectors are needed (<i>jobz</i> = 'V') and all eigenvalues are needed, that is, <i>range</i> = 'A' or <i>range</i> = 'I' and <i>il</i> = 1 and <i>iu</i> = <i>n</i> .
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length (2* <i>n</i>), where the values (2* <i>m</i>) are significant.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted. Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.

range

Restored based on the presence of arguments *vl*, *vu*, *il*, *iu* as follows:
range = 'V', if one of or both *vl* and *vu* are present, *range* = 'I',
 if one of or both *il* and *iu* are present, *range* = 'A', if none of *vl*,
vu, *il*, *iu* is present, Note that there will be an error condition if one
 of or both *vl* and *vu* are present and at the same time one of or both
il and *iu* are present.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where *nb* is the maximum of the blocksize for ?hetrd and ?unmtr returned by [ilaenv](#).

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *lrwork*, or *liwork*) for the first run or set *lwork* = -1 (*lrwork* = -1, *liwork* = -1).

If you choose the first option and set any of admissible *lwork* (or *lrwork*, *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*) on exit. Use this value (*work*(1), *rwork*(1), *iwork*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*lrwork*, *liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of ?stegr may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?spev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

FORTRAN 77:

```
call sspev(jobz, uplo, n, ap, w, z, ldz, work, info)
call dspev(jobz, uplo, n, ap, w, z, ldz, work, info)
```

Fortran 95:

```
call spev(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* in packed storage.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>ap, work</i>	REAL for <i>sspev</i> DOUBLE PRECISION for <i>dspev</i> Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.

work (*) is a workspace array, DIMENSION at least $\max(1, 3n)$.
ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

Output Parameters

w, z REAL for *sspev*
 DOUBLE PRECISION for *dspev*
 Arrays:
w(*), DIMENSION at least $\max(1, n)$.
 If *info* = 0, *w* contains the eigenvalues of the matrix *A* in ascending order.
z(*ldz*, *). The second dimension of *z* must be at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If *jobz* = 'N', then *z* is not referenced.

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spev* interface are the following:

<i>a</i>	Stands for argument <i>a_p</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?hpev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

FORTRAN 77:

```
call chpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
call zhpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hpev(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* in packed storage.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a_p</i> stores the packed upper triangular part of <i>A</i> .

If `uplo = 'L'`, `ap` stores the packed lower triangular part of A .

`n` INTEGER. The order of the matrix A ($n \geq 0$).

`ap, work` COMPLEX for `chpev`
DOUBLE COMPLEX for `zhpev`.

Arrays:
`ap(*)` contains the packed upper or lower triangle of Hermitian matrix A , as specified by `uplo`.
The dimension of `ap` must be at least $\max(1, n*(n+1)/2)$.

`work` (*) is a workspace array, DIMENSION at least $\max(1, 2n-1)$.

`ldz` INTEGER. The leading dimension of the output array z .

Constraints:
if `jobz = 'N'`, then $ldz \geq 1$;
if `jobz = 'V'`, then $ldz \geq \max(1, n)$.

`rwork` REAL for `chpev`
DOUBLE PRECISION for `zhpev`.
Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

`w` REAL for `chpev`
DOUBLE PRECISION for `zhpev`.
Array, DIMENSION at least $\max(1, n)$.
If `info = 0`, `w` contains the eigenvalues of the matrix A in ascending order.

`z` COMPLEX for `chpev`
DOUBLE COMPLEX for `zhpev`.
Array `z(ldz,*)`.
The second dimension of `z` must be at least $\max(1, n)$.
If `jobz = 'V'`, then if `info = 0`, `z` contains the orthonormal eigenvectors of the matrix A , with the i -th column of `z` holding the eigenvector associated with $w(i)$.
If `jobz = 'N'`, then `z` is not referenced.

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = <i>i</i>, then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpev` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array A of size $(n * (n + 1) / 2)$.
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix Z of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?spevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix held in packed storage.

Syntax

FORTRAN 77:

```
call sspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
call dspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call spevd(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as:

$$A = Z^* \Lambda^* Z^T.$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	REAL for <i>sspevd</i> DOUBLE PRECISION for <i>dspevd</i> Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of symmetric matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.

<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints: if $n \leq 1$, then $lwork \geq 1$; if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq 2*n$; if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq n^2 + 6*n + 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the required sizes of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, its dimension $\max(1, liwork)$.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i>. Constraints: if $n \leq 1$, then $liwork \geq 1$; if <i>jobz</i> = 'N' and $n > 1$, then $liwork \geq 1$; if <i>jobz</i> = 'V' and $n > 1$, then $liwork \geq 5*n+3$. If <i>liwork</i> = -1, then a workspace query is assumed; the routine only calculates the required sizes of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.

Output Parameters

<i>w, z</i>	REAL for <code>sspevd</code> DOUBLE PRECISION for <code>dspevd</code>

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$.

$z(ldz,*)$.

The second dimension of z must be: at least 1 if $jobz = 'N'$; at least $\max(1, n)$ if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A .

If $jobz = 'N'$, then z is not referenced.

ap

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A .

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required $lwork$.

$iwork(1)$

On exit, if $info = 0$, then $iwork(1)$ returns the required $liwork$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spevd` interface are the following:

a	Stands for argument ap in Fortran 77 interface. Holds the array A of size $(n*(n+1)/2)$.
w	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.

jobz Restored based on the presence of the argument *z* as follows:
jobz = 'V', if *z* is present,
jobz = 'N', if *z* is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [?hpevd](#).

See also [?syevd](#) for matrices held in full storage, and [?sbevd](#) for banded matrices.

?hpevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a complex Hermitian matrix held in packed storage.

Syntax

FORTRAN 77:

```
call chpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork,
liwork, info)

call zhpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork,
liwork, info)
```

Fortran 95:

```
call hpevd(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as: $A = Z^* \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A^* z_i = \lambda_i^* z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	COMPLEX for <i>chpevd</i> DOUBLE COMPLEX for <i>zhpevd</i> Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of Hermitian matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints:

if $jobz = 'N'$, then $ldz \geq 1$;
 if $jobz = 'V'$, then $ldz \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.
 Constraints:
 if $n \leq 1$, then $lwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $lwork \geq n$;
 if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork REAL for *chpevd*
 DOUBLE PRECISION for *zhpevd*
 Workspace array, its dimension $\max(1, lrwork)$.

lrwork INTEGER.
 The dimension of the array *rwork*. Constraints:
 if $n \leq 1$, then $lrwork \geq 1$;
 if $jobz = 'N'$ and $n > 1$, then $lrwork \geq n$;
 if $jobz = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.
 If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
 The dimension of the array *iwork*.
 Constraints:
 if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w	REAL for <code>chpevd</code> DOUBLE PRECISION for <code>zhpevd</code> Array, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$.
z	COMPLEX for <code>chpevd</code> DOUBLE COMPLEX for <code>zhpevd</code> Array, DIMENSION $(ldz,*)$. The second dimension of z must be: at least 1 if $jobz = 'N'$; at least $\max(1, n)$ if $jobz = 'V'$. If $jobz = 'V'$, then this array is overwritten by the unitary matrix Z which contains the eigenvectors of A. If $jobz = 'N'$, then z is not referenced.
ap	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A.
$work(1)$	On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.
$rwork(1)$	On exit, if $info = 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.
$iwork(1)$	On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.
$info$	INTEGER. If $info = 0$, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpevd` interface are the following:

<i>a</i>	Stands for argument <i>a_p</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n + 1) / 2)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T + E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set $lwork = -1$ ($liwork = -1$, $lrwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [?spevd](#).

See also [?heevd](#) for matrices held in full storage, and [?hbevd](#) for banded matrices.

?spevx

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

FORTRAN 77:

```
call sspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,
work, iwork, ifail, info)
```

```
call dspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,
work, iwork, ifail, info)
```

Fortran 95:

```
call spevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues.

	If <i>range</i> = 'V', the routine computes eigenvalues <i>lambda(i)</i> in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>ap, work</i>	REAL for <i>sspevx</i> DOUBLE PRECISION for <i>dspevx</i> Arrays: <i>ap</i>(*) contains the packed upper or lower triangle of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>. The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i>(*) is a workspace array, DIMENSION at least $\max(1, 8n)$.
<i>vl, vu</i>	REAL for <i>sspevx</i> DOUBLE PRECISION for <i>dspevx</i> If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for <i>sspevx</i> DOUBLE PRECISION for <i>dspevx</i> The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. Constraints:

if $jobz = 'N'$, then $ldz \geq 1$;
 if $jobz = 'V'$, then $ldz \geq \max(1, n)$.
iwork INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A .

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$,
 $m = iu-il+1$.

w, z REAL for `sspevx`
 DOUBLE PRECISION for `dspevx`
Arrays:
w(*), DIMENSION at least $\max(1, n)$.
 If $info = 0$, contains the selected eigenvalues of the matrix A in ascending order.
z(ldz ,*).
 The second dimension of z must be at least $\max(1, m)$.
 If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.
 If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If $jobz = 'N'$, then z is not referenced.
 Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail INTEGER.
 Array, DIMENSION at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spevx* interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector of length (<i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present,

`range = 'I'`, if one of or both `il` and `iu` are present,
`range = 'A'`, if none of `vl`, `vu`, `il`, `iu` is present,
 Note that there will be an error condition if one of or both `vl` and `vu`
 are present and at the same time one of or both `il` and `iu` are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If `abstol` is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to $2 * ?lamch('S')$.

?hpevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

FORTRAN 77:

```
call chpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,
work, rwork, iwork, ifail, info)

call zhpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,
work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hpevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>ap, work</i>	COMPLEX for <i>chpevx</i> DOUBLE COMPLEX for <i>zhpevx</i> Arrays: <i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>. The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i>(*) is a workspace array, DIMENSION at least $\max(1, 2n)$.
<i>vl, vu</i>	REAL for <i>chpevx</i> DOUBLE PRECISION for <i>zhpevx</i> If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

	Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If $range = 'A'$ or $'V'$, il and iu are not referenced.
<i>abstol</i>	REAL for <code>chpevx</code> DOUBLE PRECISION for <code>zhpevx</code> The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. Constraints: if $jobz = 'N'$, then $ldz \geq 1$; if $jobz = 'V'$, then $ldz \geq \max(1, n)$.
<i>rwork</i>	REAL for <code>chpevx</code> DOUBLE PRECISION for <code>zhpevx</code> Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i>.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.
<i>w</i>	REAL for <code>chpevx</code> DOUBLE PRECISION for <code>zhpevx</code> Array, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the selected eigenvalues of the matrix <i>A</i> in ascending order.
<i>z</i>	COMPLEX for <code>chpevx</code> DOUBLE COMPLEX for <code>zhpevx</code> Array $z(ldz,*)$. The second dimension of <i>z</i> must be at least $\max(1, m)$.

If `jobz = 'V'`, then if `info = 0`, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in `ifail`.

If `jobz = 'N'`, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if `range = 'V'`, the exact value of m is not known in advance and an upper bound must be used.

`ifail`

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If `jobz = 'V'`, then if `info = 0`, the first m elements of `ifail` are zero; if `info > 0`, the `ifail` contains the indices the eigenvectors that failed to converge.

If `jobz = 'N'`, then `ifail` is not referenced.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

If `info = i`, then i eigenvectors failed to converge; their indices are stored in the array `ifail`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpevx` interface are the following:

<code>a</code>	Stands for argument <code>ap</code> in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
<code>w</code>	Holds the vector of length (n) .
<code>z</code>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<code>ifail</code>	Holds the vector of length (n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

<i>vl</i>	Default value for this element is $vl = -\text{HUGE}(vl)$.
<i>vu</i>	Default value for this element is $vu = \text{HUGE}(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 \cdot \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 \cdot \text{lamch}('S')$.

?sbev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
call dsbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
```

Fortran 95:

```
call sbbev(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix *A*.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).
<i>ab, work</i>	REAL for ssbev DOUBLE PRECISION for dsbev. Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$.

work (*) is a workspace array.
 The dimension of *work* must be at least $\max(1, 3n-2)$.

ldab INTEGER. The leading dimension of *ab*; must be at least $kd + 1$.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

Output Parameters

w, *z* REAL for ssbev
 DOUBLE PRECISION for dsbev
 Arrays:
w (*), DIMENSION at least $\max(1, n)$.
 If *info* = 0, contains the eigenvalues of the matrix *A* in ascending order.
z(*ldz*,*).
 The second dimension of *z* must be at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If *jobz* = 'N', then *z* is not referenced.

ab On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.
 If *uplo* = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix *T* are returned in rows *kd* and *kd*+1 of *ab*, and if *uplo* = 'L', the diagonal and first subdiagonal of *T* are returned in the first two rows of *ab*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then the algorithm failed to converge; *i* indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbevd` interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

?hbevd

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, rwork, info)
call zhbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hbevd(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix *A*.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ab* stores the upper triangular part of *A*.
 If *uplo* = 'L', *ab* stores the lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

kd INTEGER. The number of super- or sub-diagonals in *A* ($kd \geq 0$).

ab, work COMPLEX for chbev
 DOUBLE COMPLEX for zhbev.
Arrays:
ab (*ldab*,*) is an array containing either upper or lower triangular part of the Hermitian matrix *A* (as specified by *uplo*) in band storage format.
 The second dimension of *ab* must be at least $\max(1, n)$.
work (*) is a workspace array.
 The dimension of *work* must be at least $\max(1, n)$.

ldab INTEGER. The leading dimension of *ab*; must be at least *kd* + 1.

ldz INTEGER. The leading dimension of the output array *z*.
Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

rwork REAL for chbev
 DOUBLE PRECISION for zhbev
 Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

w REAL for chbev
 DOUBLE PRECISION for zhbev
 Array, DIMENSION at least $\max(1, n)$.
 If *info* = 0, contains the eigenvalues in ascending order.

z COMPLEX for chbev
 DOUBLE COMPLEX for zhbev.
 Array *z*(*ldz*,*).

	The second dimension of z must be at least $\max(1, n)$. If $jobz = 'V'$, then if $info = 0$, z contains the orthonormal eigenvectors of the matrix A, with the i-th column of z holding the eigenvector associated with $w(i)$. If $jobz = 'N'$, then z is not referenced.
ab	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. If $uplo = 'U'$, the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows kd and $kd+1$ of ab, and if $uplo = 'L'$, the diagonal and first subdiagonal of T are returned in the first two rows of ab.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the ith parameter had an illegal value. If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbev` interface are the following:

a	Stands for argument ab in Fortran 77 interface. Holds the array A of size $(kd+1, n)$.
w	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$uplo$	Must be <code>'U'</code> or <code>'L'</code> . The default value is <code>'U'</code> .
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

?sbevd

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric band matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call ssbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, iwork, liwork, info)
```

```
call dsbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call sbevd(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric band matrix A . In other words, it can compute the spectral factorization of A as:

$$A = Z \Lambda Z^T$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A .

	If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).
<i>ab, work</i>	REAL for <i>ssbevd</i> DOUBLE PRECISION for <i>dsbevd</i> . Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraints: if $n \leq 1$, then $lwork \geq 1$; if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq 2n$; if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq 2*n^2 + 5*n + 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>liwork</i> is issued by xerbla . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, its dimension $\max(1, liwork)$.
<i>liwork</i>	INTEGER.

The dimension of the array *iwork*. Constraints: if $n \leq 1$, then $liwork < 1$; if $job = 'N'$ and $n > 1$, then $liwork < 1$; if $job = 'V'$ and $n > 1$, then $liwork < 5*n+3$. If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>w</i> , <i>z</i>	REAL for ssbevd DOUBLE PRECISION for dsbevd Arrays: <i>w</i>(*), DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i>. <i>z</i>(<i>ldz</i>,*). The second dimension of <i>z</i> must be: at least 1 if $job = 'N'$; at least $\max(1, n)$ if $job = 'V'$. If $job = 'V'$, then this array is overwritten by the orthogonal matrix <i>Z</i> which contains the eigenvectors of <i>A</i>. The <i>i</i>-th column of <i>Z</i> contains the eigenvector which corresponds to the eigenvalue <i>w</i>(<i>i</i>). If $job = 'N'$, then <i>z</i> is not referenced.
<i>ab</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbevd` interface are the following:

a	Stands for argument ab in Fortran 77 interface. Holds the array A of size $(kd+1, n)$.
w	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that

$\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If any of admissible $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work, iwork$) on exit. Use this value ($work(1), iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if *work* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [?hbevd](#).

See also [?syevd](#) for matrices held in full storage, and [?spevd](#) for matrices held in packed storage.

?hbevd

Computes all eigenvalues and (optionally) all eigenvectors of a complex Hermitian band matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call chbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, rwork, lrwork,
iwork, liwork, info)

call zhbevd(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, lwork, rwork, lrwork,
iwork, liwork, info)
```

Fortran 95:

```
call hbevd(a, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian band matrix *A*. In other words, it can compute the spectral factorization of *A* as: $A = Z \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and *Z* is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).
<i>ab, work</i>	COMPLEX for <i>chbevd</i> DOUBLE COMPLEX for <i>zhbevd</i>. Arrays: <i>ab</i> (<i>ldab</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, its dimension $\max(1, lwork)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i>; must be at least $kd+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. Constraints: if <i>jobz</i> = 'N', then $ldz \geq 1$; if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints: if $n \leq 1$, then $lwork \geq 1$; if <i>jobz</i> = 'N' and $n > 1$, then $lwork \geq n$; if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq 2*n^2$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork

REAL for chbevd
DOUBLE PRECISION for zhbevd
Workspace array, DIMENSION at least *lrwork*.

lrwork

INTEGER.
The dimension of the array *rwork*.
Constraints:

if $n \leq 1$, then $lrwork \geq 1$;
if $jobz = 'N'$ and $n > 1$, then $lrwork \geq n$;
if $jobz = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2 + 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER. Workspace array, DIMENSION $\max(1, liwork)$.

liwork

INTEGER.
The dimension of the array *iwork*.
Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $liwork \geq 1$;
if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>w</i>	REAL for <code>chbevd</code> DOUBLE PRECISION for <code>zhbevd</code> Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i>.
<i>z</i>	COMPLEX for <code>chbevd</code> DOUBLE COMPLEX for <code>zhbevd</code> Array, DIMENSION (<i>ldz</i>, *). The second dimension of <i>z</i> must be: at least 1 if <i>jobz</i> = 'N'; at least $\max(1, n)$ if <i>jobz</i> = 'V'. If <i>jobz</i> = 'V', then this array is overwritten by the unitary matrix <i>Z</i> which contains the eigenvectors of <i>A</i>. The <i>i</i>-th column of <i>Z</i> contains the eigenvector which corresponds to the eigenvalue <i>w</i>(<i>i</i>). If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>ab</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then the real part of <i>work</i>(1) returns the required minimal size of <i>lwork</i>.
<i>rwork</i> (1)	On exit, if <i>lrwork</i> > 0, then <i>rwork</i>(1) returns the required minimal size of <i>lrwork</i>.
<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i>(1) returns the required minimal size of <i>liwork</i>.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i>, then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbevd` interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T + E$ such that $\|E\|_2 = O(\epsilon) \|T\|_2$, where ϵ is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set *lwork* = -1 (*liwork* = -1, *lrwork* = -1).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set *lwork* = -1 (*liwork* = -1, *lrwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [?sbevd](#).

See also [?heevd](#) for matrices held in full storage, and [?hpevd](#) for matrices held in packed storage.

?sbevx

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol,
m, w, z, ldz, work, iwork, ifail, info)

call dsbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol,
m, w, z, ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call sbevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues in range <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($kd \geq 0$).
<i>ab, work</i>	REAL for <i>ssbev</i> DOUBLE PRECISION for <i>dsbev</i> . Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 7n)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd + 1$.
<i>vl, vu</i>	REAL for <i>ssbev</i> DOUBLE PRECISION for <i>dsbev</i> . If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for <i>chpev</i> DOUBLE PRECISION for <i>zhpev</i> The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldq, ldz</i>	INTEGER. The leading dimensions of the output arrays <i>q</i> and <i>z</i> , respectively. Constraints: $ldq \geq 1, ldz \geq 1$;

If $jobz = 'V'$, then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$.

iwork

INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

q

REAL for ssbevz DOUBLE PRECISION for dsbevz.

Array, DIMENSION (ldz, n).

If $jobz = 'V'$, the n -by- n orthogonal matrix is used in the reduction to tridiagonal form.

If $jobz = 'N'$, the array *q* is not referenced.

m

INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.

w, z

REAL for ssbevz

DOUBLE PRECISION for dsbevz

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$. The first m elements of *w* contain the selected eigenvalues of the matrix *A* in ascending order.

$z(ldz,*)$.

The second dimension of *z* must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the i -th column of *z* holding the eigenvector associated with $w(i)$. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then *z* is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ab

On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.

If $uplo = 'U'$, the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows kd and $kd+1$ of ab , and if $uplo = 'L'$, the diagonal and first subdiagonal of T are returned in the first two rows of ab .

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbevx` interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values n and m are significant.
<i>ifail</i>	Holds the vector of length (n) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.

<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if either <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i>, <i>vu</i>, <i>il</i>, <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{?lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{?lamch}('S')$.

?hbevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol,
m, w, z, ldz, work, rwork, iwork, ifail, info)

call zhbevx(jobz, range, uplo, n, kd, ab, ldab, q, ldq, vl, vu, il, iu, abstol,
m, w, z, ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hbev(x, a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

jobz CHARACTER*1. Must be 'N' or 'V'.
 If *jobz* = 'N', then only eigenvalues are computed.
 If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

range CHARACTER*1. Must be 'A' or 'V' or 'I'.
 If *range* = 'A', the routine computes all eigenvalues.
 If *range* = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$.
 If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ab* stores the upper triangular part of A .
 If *uplo* = 'L', *ab* stores the lower triangular part of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

kd INTEGER. The number of super- or sub-diagonals in A ($kd \geq 0$).

ab, work COMPLEX for chbev(x)
 DOUBLE COMPLEX for zhbev(x).
Arrays:
ab (*ldab*,*) is an array containing either upper or lower triangular part of the Hermitian matrix A (as specified by *uplo*) in band storage format.
 The second dimension of *ab* must be at least $\max(1, n)$.
work (*) is a workspace array.

	The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The leading dimension of <i>ab</i> ; must be at least $kd + 1$.
<i>vl, vu</i>	REAL for <i>chbev</i> x DOUBLE PRECISION for <i>zhbev</i> x. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for <i>chbev</i> x DOUBLE PRECISION for <i>zhbev</i> x. The absolute error tolerance to which each eigenvalue is required. See <i>Application notes</i> for details on error tolerance.
<i>ldq, ldz</i>	INTEGER. The leading dimensions of the output arrays <i>q</i> and <i>z</i> , respectively. Constraints: $ldq \geq 1, ldz \geq 1$; If <i>jobz</i> = 'V', then $ldq \geq \max(1, n)$ and $ldz \geq \max(1, n)$.
<i>rwork</i>	REAL for <i>chbev</i> x DOUBLE PRECISION for <i>zhbev</i> x Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>q</i>	COMPLEX for <i>chbev</i> x DOUBLE COMPLEX for <i>zhbev</i> x. Array, DIMENSION (ldz, n).

If *jobz* = 'V', the *n*-by-*n* unitary matrix is used in the reduction to tridiagonal form.
 If *jobz* = 'N', the array *q* is not referenced.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$.
 If *range* = 'A', *m* = *n*, and if *range* = 'I', *m* = *iu-il*+1.

w REAL for chbev
 DOUBLE PRECISION for zhbev
 Array, DIMENSION at least $\max(1, n)$. The first *m* elements contain the selected eigenvalues of the matrix *A* in ascending order.

z COMPLEX for chbev
 DOUBLE COMPLEX for zhbev.
 Array *z*(*ldz*,*).
 The second dimension of *z* must be at least $\max(1, m)$.
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If *jobz* = 'N', then *z* is not referenced.
 Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ab On exit, this array is overwritten by the values generated during the reduction to tridiagonal form.
 If *uplo* = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix *T* are returned in rows *kd* and *kd*+1 of *ab*, and if *uplo* = 'L', the diagonal and first subdiagonal of *T* are returned in the first two rows of *ab*.

ifail INTEGER.
 Array, DIMENSION at least $\max(1, n)$.

If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.
 If *jobz* = 'N', then *ifail* is not referenced.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hbev*x interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector of length (n) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if either <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows:

`range = 'V'`, if one of or both `vl` and `vu` are present,
`range = 'I'`, if one of or both `il` and `iu` are present,
`range = 'A'`, if none of `vl`, `vu`, `il`, `iu` is present,
 Note that there will be an error condition if one of or both `vl` and `vu`
 are present and at the same time one of or both `il` and `iu` are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If `abstol` is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with `info > 0`, indicating that some eigenvectors did not converge, try setting `abstol` to $2 * \text{lamch}('S')$.

?stev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstev(jobz, n, d, e, z, ldz, work, info)
call dstev(jobz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call stev(d, e [,z] [,info])
```

Description

This routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A .

Input Parameters

`jobz` CHARACTER*1. Must be 'N' or 'V'.

If *jobz* = 'N', then only eigenvalues are computed.
 If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

d, e, work REAL for *sstev*
 DOUBLE PRECISION for *dsteve*.
Arrays:
d(*) contains the *n* diagonal elements of the tridiagonal matrix *A*.
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the *n*-1 subdiagonal elements of the tridiagonal matrix *A*.
 The dimension of *e* must be at least $\max(1, n-1)$. The *n*-th element of this array is used as workspace.
work(*) is a workspace array.
 The dimension of *work* must be at least $\max(1, 2n-2)$.
 If *jobz* = 'N', *work* is not referenced.

ldz INTEGER. The leading dimension of the output array *z*; $ldz \geq 1$. If *jobz* = 'V' then $ldz \geq \max(1, n)$.

Output Parameters

d On exit, if *info* = 0, contains the eigenvalues of the matrix *A* in ascending order.

z REAL for *sstev*
 DOUBLE PRECISION for *dsteve*
Array, DIMENSION (*ldz*, *).
 The second dimension of *z* must be at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with the eigenvalue returned in *d*(*i*).
 If *job* = 'N', then *z* is not referenced.

e On exit, this array is overwritten with intermediate results.

info INTEGER.
 If *info* = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge;

i elements of e did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stev` interface are the following:

d	Holds the vector of length (n) .
e	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

?stevd

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call sstevd(jobz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
```

```
call dstevd(jobz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call stevd(d, e [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization of T

as: $T = Z \Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$T^* z_i = \lambda_i * z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the *QL* or *QR* algorithm.

There is no complex analogue of this routine.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>n</i>	INTEGER. The order of the matrix <i>T</i> ($n \geq 0$).
<i>d, e, work</i>	REAL for <i>sstevd</i> DOUBLE PRECISION for <i>dstevd</i>. Arrays: <i>d</i>(*) contains the <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i>(*) contains the <i>n</i>-1 off-diagonal elements of <i>T</i>. The dimension of <i>e</i> must be at least $\max(1, n-1)$. The <i>n</i>-th element of this array is used as workspace. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least <i>lwork</i>.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. Constraints: $ldz \geq 1$ if <i>job</i> = 'N'; $ldz < \max(1, n)$ if <i>job</i> = 'V'.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints: if <i>jobz</i> = 'N' or $n \leq 1$, then $lwork \geq 1$; if <i>jobz</i> = 'V' and $n > 1$, then $lwork \geq n^2 + 4*n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$.

Constraints:

if $jobz = 'N'$ or $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

d

On exit, if $info = 0$, contains the eigenvalues of the matrix T in ascending order.

See also $info$.

z

REAL for `ssteve`

DOUBLE PRECISION for `dsteve`

Array, DIMENSION ($ldz, *$).

The second dimension of z must be:

at least 1 if $jobz = 'N'$;

at least $\max(1, n)$ if $jobz = 'V'$.

If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of T .

If $jobz = 'N'$, then z is not referenced.

e

On exit, this array is overwritten with intermediate results.

$work(1)$

On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i>, then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stevd` interface are the following:

<i>d</i>	Holds the vector of length (<i>n</i>).
<i>e</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>z</i> of size (<i>n</i> , <i>n</i>).
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and m_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?stevx

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstevx(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, work,
iwork, ifail, info)
```

```
call dstevx(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, work,
iwork, ifail, info)
```

Fortran 95:

```
call stevx(d, e, w [, z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix *A*. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>d, e, work</i>	REAL for <i>sstevx</i> DOUBLE PRECISION for <i>dstevx</i>. Arrays: <i>d</i>(*) contains the <i>n</i> diagonal elements of the tridiagonal matrix <i>A</i>. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i>(*) contains the <i>n</i>-1 subdiagonal elements of <i>A</i>. The dimension of <i>e</i> must be at least $\max(1, n-1)$. The <i>n</i>-th element of this array is used as workspace. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 5n)$.
<i>vl, vu</i>	REAL for <i>sstevx</i> DOUBLE PRECISION for <i>dstevx</i>. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.

abstol REAL for `sstevx`
DOUBLE PRECISION for `dstevx`. The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz INTEGER. The leading dimensions of the output array *z*;
 $ldz \geq 1$. If *jobz* = 'V', then $ldz \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$.
If *range* = 'A', $m = n$, and if *range* = 'I', $m = iu - il + 1$.

w, *z* REAL for `sstevx`
DOUBLE PRECISION for `dstevx`.
Arrays:
w(*), DIMENSION at least $\max(1, n)$.
The first *m* elements of *w* contain the selected eigenvalues of the matrix *A* in ascending order.
z(*ldz*,*).
The second dimension of *z* must be at least $\max(1, m)$.
If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
If *jobz* = 'N', then *z* is not referenced.
Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

d, *e* On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.

ifail INTEGER.

Array, *DIMENSION* at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices of the eigenvectors that failed to converge.
 If *jobz* = 'N', then *ifail* is not referenced.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *stevx* interface are the following:

<i>d</i>	Holds the vector of length (<i>n</i>).
<i>e</i>	Holds the vector of length (<i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector of length (<i>n</i>).
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present,

$range = 'I'$, if one of or both il and iu are present,
 $range = 'A'$, if none of vl, vu, il, iu is present,
 Note that there will be an error condition if one of or both vl and vu
 are present and at the same time one of or both il and iu are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * ||A||^1$ is used instead. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \lambda_{\text{lamch}}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, set $abstol$ to $2 * \lambda_{\text{lamch}}('S')$.

?stevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call sstevr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)

call dstevr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call stevr(d, e, w [, z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, the routine calls `?stemr` to compute the eigenspectrum using Relatively Robust Representations. `?stegr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various “good” $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the *i*-th unreduced block of *T*:

- a.** Compute $T - \sigma_i = L_i^*D_i^*L_i^T$, such that $L_i^*D_i^*L_i^T$ is a relatively robust representation.
- b.** Compute the eigenvalues, λ_j , of $L_i^*D_i^*L_i^T$ to high relative accuracy by the *dqds* algorithm.
- c.** If there is a cluster of close eigenvalues, “choose” σ_i close to the cluster, and go to Step (a).
- d.** Given the approximate eigenvalue λ_j of $L_i^*D_i^*L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter *abstol*.

The routine `?stevr` calls `?stemr` when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard. `?stevr` calls `?stebz` and `?stein` on non-IEEE machines and when partial spectrum requests are made.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu.$ If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> . For <i>range</i> = 'V' or 'I' and $iu - il < n - 1$, <code>sstebz/dstebz</code> and <code>sstein/dstein</code> are called.
<i>n</i>	INTEGER. The order of the matrix <i>T</i> ($n \geq 0$).
<i>d, e, work</i>	REAL for <code>sstevr</code>

DOUBLE PRECISION for `dstevr`.

Arrays:
`d(*)` contains the n diagonal elements of the tridiagonal matrix T .
The dimension of d must be at least $\max(1, n)$.
`e(*)` contains the $n-1$ subdiagonal elements of A .
The dimension of e must be at least $\max(1, n-1)$. The n -th element of this array is used as workspace.
`work` is a workspace array, its dimension $\max(1, lwork)$.

`vl, vu` REAL for `sstevr`
DOUBLE PRECISION for `dstevr`.
If `range = 'V'`, the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: `vl < vu`.
If `range = 'A'` or `'I'`, `vl` and `vu` are not referenced.

`il, iu` INTEGER.
If `range = 'I'`, the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
If `range = 'A'` or `'V'`, `il` and `iu` are not referenced.

`abstol` REAL for `ssyevr`
DOUBLE PRECISION for `dsyevr`.
The absolute error tolerance to which each eigenvalue/eigenvector is required.
If `jobz = 'V'`, the eigenvalues and eigenvectors output have residual norms bounded by `abstol`, and the dot products between different eigenvectors are bounded by `abstol`. If `abstol < n * eps * |T|`, then $n * eps * |T|$ will be used in its place, where `eps` is the machine precision, and $|T|$ is the 1-norm of the matrix T . The eigenvalues are computed to an accuracy of $eps * |T|$ irrespective of `abstol`.
If high relative accuracy is important, set `abstol` to `?lamch('S')`.

`ldz` INTEGER. The leading dimension of the output array z .
Constraints:

ldz ≥ 1 if *jobz* = 'N';
ldz $\geq \max(1, n)$ if *jobz* = 'V'.
lwork INTEGER.
The dimension of the array *work*. Constraint:
lwork $\geq \max(1, 20*n)$.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.
iwork INTEGER.
Workspace array, its dimension $\max(1, liwork)$.
liwork INTEGER.
The dimension of the array *iwork*,
liwork $\geq \max(1, 10*n)$.
If *liwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', *m* = *n*, and if *range* = 'I',
m = *iu-il*+1.
w, z REAL for *sstevr*
DOUBLE PRECISION for *dstevr*.
Arrays:
w(*), DIMENSION at least $\max(1, n)$.
The first *m* elements of *w* contain the selected eigenvalues of the matrix *T* in ascending order.
z(*ldz*,*).
The second dimension of *z* must be at least $\max(1, m)$.

	If <code>jobz = 'V'</code>, then if <code>info = 0</code>, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of z holding the eigenvector associated with $w(i)$. If <code>jobz = 'N'</code>, then z is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z; if <code>range = 'V'</code>, the exact value of m is not known in advance and an upper bound must be used.
<code>d, e</code>	On exit, these arrays may be multiplied by a constant factor chosen to avoid overflow or underflow in computing the eigenvalues.
<code>isuppz</code>	INTEGER. Array, DIMENSION at least $2 * \max(1, m)$. The support of the eigenvectors in z, i.e., the indices indicating the nonzero elements in z. The i-th eigenvector is nonzero only in elements <code>isuppz(2i-1)</code> through <code>isuppz(2i)</code>. Implemented only for <code>range = 'A'</code> or <code>'I'</code> and <code>iu-il = n-1</code>.
<code>work(1)</code>	On exit, if <code>info = 0</code> , then <code>work(1)</code> returns the required minimal size of <code>lwork</code> .
<code>iwork(1)</code>	On exit, if <code>info = 0</code> , then <code>iwork(1)</code> returns the required minimal size of <code>liwork</code> .
<code>info</code>	INTEGER. If <code>info = 0</code>, the execution is successful. If <code>info = -i</code>, the i-th parameter had an illegal value. If <code>info = i</code>, an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stevr` interface are the following:

<code>d</code>	Holds the vector of length (n) .
<code>e</code>	Holds the vector of length (n) .

<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length ($2*n$), where the values ($2*m$) are significant.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

Normal execution of the routine `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if `lwork` (`liwork`) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving nonsymmetric eigenproblems. See also [computational routines](#) that can be called to solve these problems.

[Table 4-11](#) lists all such driver routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-11 Driver Routines for Solving Nonsymmetric Eigenproblems

Routine Name	Operation performed
<code>?gees</code>	Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.
<code>?geesx</code>	Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.
<code>?geev</code>	Computes the eigenvalues and left and right eigenvectors of a general matrix.
<code>?geevx</code>	Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

?gees

Computes the eigenvalues and Schur factorization of a general matrix, and orders the factorization so that selected eigenvalues are at the top left of the Schur form.

Syntax

FORTRAN 77:

```
call sgees(jobvs, sort, select, n, a, lda, sdim, wr, wi, vs, ldvs, work,
lwork, bwork, info)

call dgees(jobvs, sort, select, n, a, lda, sdim, wr, wi, vs, ldvs, work,
lwork, bwork, info)

call cgees(jobvs, sort, select, n, a, lda, sdim, w, vs, ldvs, work, lwork,
rwork, bwork, info)

call zgees(jobvs, sort, select, n, a, lda, sdim, w, vs, ldvs, work, lwork,
rwork, bwork, info)
```

Fortran 95:

```
call gees(a, wr, wi [,vs] [,select] [,sdim] [,info])

call gees(a, w [,vs] [,select] [,sdim] [,info])
```

Description

This routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{pmatrix} a & b \\ c & a \end{pmatrix}$$

where $b^*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

jobvs CHARACTER*1. Must be 'N' or 'V'.
 If *jobvs* = 'N', then Schur vectors are not computed.
 If *jobvs* = 'V', then Schur vectors are computed.

sort CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.
 If *sort* = 'N', then eigenvalues are not ordered.
 If *sort* = 'S', eigenvalues are ordered (see *select*).

select LOGICAL FUNCTION of two REAL arguments for real flavors.
 LOGICAL FUNCTION of one COMPLEX argument for complex flavors.
select must be declared EXTERNAL in the calling subroutine.
 If *sort* = 'S', *select* is used to select eigenvalues to sort to the top left of the Schur form.
 If *sort* = 'N', *select* is not referenced.

For real flavors:
 An eigenvalue $w_r(j) + \text{sqrt}(-1) * w_i(j)$ is selected if *select*($w_r(j)$, $w_i(j)$) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.
 Note that a selected complex eigenvalue may no longer satisfy *select*($w_r(j)$, $w_i(j)$) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case *info* may be set to $n+2$ (see *info* below).

For complex flavors:
 An eigenvalue $w(j)$ is selected if *select*($w(j)$) is true.

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for sgees DOUBLE PRECISION for dgees COMPLEX for cgees DOUBLE COMPLEX for zgees. Arrays: <i>a(lda,*)</i> is an array containing the <i>n</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>ldvs</i>	INTEGER. The leading dimension of the output array <i>vs</i> . Constraints: $ldvs \geq 1$; $ldvs \geq \max(1, n)$ if <i>jobvs</i> = 'V'.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraint: $lwork \geq \max(1, 3n)$ for real flavors; $lwork \geq \max(1, 2n)$ for complex flavors. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla .
<i>rwork</i>	REAL for cgees DOUBLE PRECISION for zgees Workspace array, DIMENSION at least $\max(1, n)$. Used in complex flavors only.
<i>bwork</i>	LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$. Not referenced if <i>sort</i> = 'N'.

Output Parameters

<i>a</i>	On exit, this array is overwritten by the real-Schur/Schur form <i>T</i> .

sdim INTEGER.
 If *sort* = 'N', *sdim* = 0.
 If *sort* = 'S', *sdim* is equal to the number of eigenvalues (after sorting) for which *select* is true.
 Note that for real flavors complex conjugate pairs for which *select* is true for either eigenvalue count as 2.

wr, wi REAL for sgees
 DOUBLE PRECISION for dgees
 Arrays, DIMENSION at least max(1, *n*) each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form *T*. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w COMPLEX for cgees
 DOUBLE COMPLEX for zgees.
 Array, DIMENSION at least max(1, *n*). Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form *T*.

vs REAL for sgees
 DOUBLE PRECISION for dgees
 COMPLEX for cgees
 DOUBLE COMPLEX for zgees.
 Array *vs(ldvs,*)*; the second dimension of *vs* must be at least max(1, *n*).
 If *jobvs* = 'V', *vs* contains the orthogonal/unitary matrix *Z* of Schur vectors.
 If *jobvs* = 'N', *vs* is not referenced.

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*th parameter had an illegal value.
 If *info* = *i*, and
 $i \leq n$:

the QR algorithm failed to compute all the eigenvalues; elements $1:ilo-1$ and $i+1:n$ of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged; if $jobvs = 'V'$, vs contains the matrix which reduces A to its partially converged Schur form;
 $i = n+1$:
the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);
 $i = n+2$:
after reordering, round-off changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy $select = .TRUE..$ This could also be caused by underflow due to scaling.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gees` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>wr</i>	Holds the vector of length (n) . Used in real flavors only.
<i>wi</i>	Holds the vector of length (n) . Used in real flavors only.
<i>w</i>	Holds the vector of length (n) . Used in complex flavors only.
<i>vs</i>	Holds the matrix VS of size (n, n) .
<i>jobvs</i>	Restored based on the presence of the argument <i>vs</i> as follows: $jobvs = 'V'$, if <i>vs</i> is present, $jobvs = 'N'$, if <i>vs</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: $sort = 'S'$, if <i>select</i> is present, $sort = 'N'$, if <i>select</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geesx

Computes the eigenvalues and Schur factorization of a general matrix, orders the factorization and computes reciprocal condition numbers.

Syntax

FORTRAN 77:

```
call sgeesx(jobvs, sort, select, sense, n, a, lda, sdim, wr, wi, vs, ldvs,
rconde, rcondv, work, lwork, iwork, liwork, bwork, info)

call dgeesx(jobvs, sort, select, sense, n, a, lda, sdim, wr, wi, vs, ldvs,
rconde, rcondv, work, lwork, iwork, liwork, bwork, info)

call cgeesx(jobvs, sort, select, sense, n, a, lda, sdim, w, vs, ldvs, rconde,
rcondv, work, lwork, rwork, bwork, info)

call zgeesx(jobvs, sort, select, sense, n, a, lda, sdim, w, vs, ldvs, rconde,
rcondv, work, lwork, rwork, bwork, info)
```

Fortran 95:

```
call geesx(a, wr, wi [,vs] [,select] [,sdim] [,rconde] [,rconde] [,info])
call geesx(a, w [,vs] [,select] [,sdim] [,rconde] [,rconde] [,info])
```

Description

This routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues, the real-Schur/Schur form T , and, optionally, the matrix of Schur vectors Z . This gives the Schur factorization $A = Z^* T^* Z^H$.

Optionally, it also orders the eigenvalues on the diagonal of the real-Schur/Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (*rconde*); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (*rcondv*). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers *rconde* and *rcondv*, see [LUG], Section 4.10 (where these quantities are called *s* and *sep* respectively).

A real matrix is in real-Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{pmatrix} a & b \\ c & a \end{pmatrix}$$

where $b^*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$

A complex matrix is in Schur form if it is upper triangular.

Input Parameters

<i>jobvs</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvs</i> = 'N', then Schur vectors are not computed. If <i>jobvs</i> = 'V', then Schur vectors are computed.
<i>sort</i>	CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>select</i>).
<i>select</i>	LOGICAL FUNCTION of two REAL arguments for real flavors.

LOGICAL FUNCTION of one COMPLEX argument for complex flavors.

select must be declared EXTERNAL in the calling subroutine.

If *sort* = 'S', *select* is used to select eigenvalues to sort to the top left of the Schur form.

If *sort* = 'N', *select* is not referenced.

For real flavors:

An eigenvalue $w_r(j) + \sqrt{-1} * w_i(j)$ is selected if *select*(*w_r*(*j*), *w_i*(*j*)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that a selected complex eigenvalue may no longer satisfy *select*(*w_r*(*j*), *w_i*(*j*)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case *info* may be set to *n*+2 (see *info* below).

For complex flavors:

An eigenvalue *w*(*j*) is selected if *select*(*w*(*j*)) is true.

sense

CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If *sense* = 'N', none are computed;

If *sense* = 'E', computed for average of selected eigenvalues only;

If *sense* = 'V', computed for selected right invariant subspace only;

If *sense* = 'B', computed for both.

If *sense* is 'E', 'V', or 'B', then *sort* must equal 'S'.

n

INTEGER. The order of the matrix *A* (*n* ≥ 0).

a, *work*

REAL for *sgeesx*

DOUBLE PRECISION for *dgeesx*

COMPLEX for *cgeesx*

DOUBLE COMPLEX for *zgeesx*.

Arrays:

a(*lda*,*) is an array containing the *n*-by-*n* matrix *A*.

The second dimension of *a* must be at least max(1, *n*).

work is a workspace array, its dimension max(1, *lwork*).

<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>ldvs</i>	INTEGER. The leading dimension of the output array <i>vs</i> . Constraints: $ldvs \geq 1$; $ldvs \geq \max(1, n)$ if <i>jobvs</i> = 'V'.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraint: $lwork \geq \max(1, 3n)$ for real flavors; $lwork \geq \max(1, 2n)$ for complex flavors. Also, if <i>sense</i> = 'E', 'V', or 'B', then $lwork \geq n+2*sdim*(n-sdim)$ for real flavors; $lwork \geq 2*sdim*(n-sdim)$ for complex flavors; where <i>sdim</i> is the number of selected eigenvalues computed by this routine. Note that $2*sdim*(n-sdim) \leq n*n/2$. Note also that an error is only returned if $lwork < \max(1, 2*n)$, but if <i>sense</i> = 'E', or 'V', or 'B' this may not be large enough. For good performance, <i>lwork</i> must generally be larger. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates upper bound on the optimal size of the array <i>work</i> , returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only. Not referenced if <i>sense</i> = 'N' or 'E'.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i> . Used in real flavors only. Constraint: $liwork \geq 1$; if <i>sense</i> = 'V' or 'B', $liwork \geq sdim*(n-sdim)$.
<i>rwork</i>	REAL for cgeesx DOUBLE PRECISION for zgeesx

bwork Workspace array, `DIMENSION` at least $\max(1, n)$. Used in complex flavors only.

LOGICAL. Workspace array, `DIMENSION` at least $\max(1, n)$.
Not referenced if `sort = 'N'`.

Output Parameters

a On exit, this array is overwritten by the real-Schur/Schur form T .

sdim INTEGER.
If `sort = 'N'`, `sdim` = 0.
If `sort = 'S'`, `sdim` is equal to the number of eigenvalues (after sorting) for which `select` is true.
Note that for real flavors complex conjugate pairs for which `select` is true for either eigenvalue count as 2.

wr, wi REAL for `sgeesx`
DOUBLE PRECISION for `dgeesx`
Arrays, `DIMENSION` at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output real-Schur form T . Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w COMPLEX for `cgeesx`
DOUBLE COMPLEX for `zgeesx`.
Array, `DIMENSION` at least $\max(1, n)$. Contains the computed eigenvalues. The eigenvalues are stored in the same order as they appear on the diagonal of the output Schur form T .

vs REAL for `sgeesx`
DOUBLE PRECISION for `dgeesx`
COMPLEX for `cgeesx`
DOUBLE COMPLEX for `zgeesx`.
Array `vs(ldvs,*)`; the second dimension of `vs` must be at least $\max(1, n)$.
If `jobvs = 'V'`, `vs` contains the orthogonal/unitary matrix Z of Schur vectors.
If `jobvs = 'N'`, `vs` is not referenced.

<i>rconde, rcondv</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>sense</i> = 'E' or 'B', <i>rconde</i> contains the reciprocal condition number for the average of the selected eigenvalues. If <i>sense</i> = 'N' or 'V', <i>rconde</i> is not referenced. If <i>sense</i> = 'V' or 'B', <i>rcondv</i> contains the reciprocal condition number for the selected right invariant subspace. If <i>sense</i> = 'N' or 'E', <i>rcondv</i> is not referenced.
<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the required minimal size of <i>lwork</i>.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>th parameter had an illegal value. If <i>info</i> = <i>i</i>, and <i>i</i> ≤ <i>n</i>: the <i>QR</i> algorithm failed to compute all the eigenvalues; elements 1:<i>ilo</i>-1 and <i>i</i>+1:<i>n</i> of <i>wr</i> and <i>wi</i> (for real flavors) or <i>w</i> (for complex flavors) contain those eigenvalues which have converged; if <i>jobvs</i> = 'V', <i>vs</i> contains the transformation which reduces <i>A</i> to its partially converged Schur form; <i>i</i> = <i>n</i>+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); <i>i</i> = <i>n</i>+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy <i>select</i> = .TRUE.. This could also be caused by underflow due to scaling.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geesx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>wr</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>wi</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>w</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>vs</i>	Holds the matrix <i>VS</i> of size (<i>n</i> , <i>n</i>).
<i>jobvs</i>	Restored based on the presence of the argument <i>vs</i> as follows: <i>jobvs</i> = 'V', if <i>vs</i> is present, <i>jobvs</i> = 'N', if <i>vs</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present, <i>sort</i> = 'N', if <i>select</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If you choose the first option and set any of admissible *lwork* (or *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geev

Computes the eigenvalues and left and right eigenvectors of a general matrix.

Syntax

FORTRAN 77:

```
call sgeev(jobvl, jobvr, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, work, lwork,
info)

call dgeev(jobvl, jobvr, n, a, lda, wr, wi, vl, ldvl, vr, ldvr, work, lwork,
info)

call cgeev(jobvl, jobvr, n, a, lda, w, vl, ldvl, vr, ldvr, work, lwork, rwork,
info)

call zgeev(jobvl, jobvr, n, a, lda, w, vl, ldvl, vr, ldvr, work, lwork, rwork,
info)
```

Fortran 95:

```
call geev(a, wr, wi [,vl] [,vr] [,info])
call geev(a, w [,vl] [,vr] [,info])
```

Description

This routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors. The right eigenvector $v(j)$ of A satisfies

$$A \cdot v(j) = \lambda(j) \cdot v(j)$$

where $\lambda(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)^H \cdot A = \lambda(j) \cdot u(j)^H$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$. The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Input Parameters

jobvl CHARACTER*1. Must be 'N' or 'V'.

If $jobvl = 'N'$, then left eigenvectors of A are not computed.
 If $jobvl = 'V'$, then left eigenvectors of A are computed.

jobvr CHARACTER*1. Must be 'N' or 'V'.
 If $jobvr = 'N'$, then right eigenvectors of A are not computed.
 If $jobvr = 'V'$, then right eigenvectors of A are computed.

n INTEGER. The order of the matrix A ($n \geq 0$).

a, work REAL for sgeev
 DOUBLE PRECISION for dgeev
 COMPLEX for cgeev
 DOUBLE COMPLEX for zgeev.

Arrays:
a(*lda*,*) is an array containing the n -by- n matrix A .
 The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*. Must be at least $\max(1, n)$.

ldvl, ldvr INTEGER. The leading dimensions of the output arrays *vl* and *vr*, respectively.

Constraints:
 $ldvl \geq 1; ldvr \geq 1$.
 If $jobvl = 'V'$, $ldvl \geq \max(1, n)$;
 If $jobvr = 'V'$, $ldvr \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.
Constraint:
 $lwork \geq \max(1, 3n)$, and if $jobvl = 'V'$ or $jobvr = 'V'$, $lwork < \max(1, 4n)$ (for real flavors);
 $lwork < \max(1, 2n)$ (for complex flavors).
 For good performance, *lwork* must generally be larger.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by xerbla.

rwork REAL for cgeev
DOUBLE PRECISION for zgeev
Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

a On exit, this array is overwritten by intermediate results.

wr, wi REAL for sgeev
DOUBLE PRECISION for dgeev
Arrays, DIMENSION at least $\max(1, n)$ each.
Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w COMPLEX for cgeev
DOUBLE COMPLEX for zgeev.
Array, DIMENSION at least $\max(1, n)$.
Contains the computed eigenvalues.

vl, vr REAL for sgeev
DOUBLE PRECISION for dgeev
COMPLEX for cgeev
DOUBLE COMPLEX for zgeev.
Arrays:
 $vl(ldvl,*)$; the second dimension of *vl* must be at least $\max(1, n)$.
If *jobvl* = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of *vl*, in the same order as their eigenvalues.
If *jobvl* = 'N', *vl* is not referenced.
For real flavors:
If the *j*-th eigenvalue is real, then $u(j) = vl(:, j)$, the *j*-th column of *vl*.
If the *j*-th and (*j*+1)-st eigenvalues form a complex conjugate pair, then $u(j) = vl(:, j) + i*vl(:, j+1)$ and $u(j+1) = vl(:, j) - i*vl(:, j+1)$, where $i = \sqrt{-1}$.
For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .
 $vr(ldvr, *)$; the second dimension of vr must be at least $\max(1, n)$.
 If $jobvr = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues.
 If $jobvr = 'N'$, vr is not referenced.
For real flavors:
 If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .
 If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i*vr(:, j+1)$ and $v(j+1) = vr(:, j) - i*vr(:, j+1)$, where $i = \text{sqrt}(-1)$.
For complex flavors:
 $v(j) = vr(:, j)$, the j -th column of vr .
 On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.
 INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i th parameter had an illegal value.
 If $info = i$, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements $i+1:n$ of wr and wi (for real flavors) or w (for complex flavors) contain those eigenvalues which have converged.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geev` interface are the following:

a	Holds the matrix A of size (n, n) .
wr	Holds the vector of length (n) . Used in real flavors only.
wi	Holds the vector of length (n) . Used in real flavors only.
w	Holds the vector of length (n) . Used in complex flavors only.

<i>vl</i>	Holds the matrix <i>VL</i> of size (n, n) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, n) .
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?geevx

Computes the eigenvalues and left and right eigenvectors of a general matrix, with preliminary matrix balancing, and computes reciprocal condition numbers for the eigenvalues and right eigenvectors.

Syntax

FORTRAN 77:

```
call sgeevx(balanc, jobvl, jobvr, sense, n, a, lda, wr, wi, vl, ldvl, vr,
ldvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, iwork, info)

call dgeevx(balanc, jobvl, jobvr, sense, n, a, lda, wr, wi, vl, ldvl, vr,
ldvr, ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, iwork, info)

call cgeevx(balanc, jobvl, jobvr, sense, n, a, lda, w, vl, ldvl, vr, ldvr,
ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, rwork, info)

call zgeevx(balanc, jobvl, jobvr, sense, n, a, lda, w, vl, ldvl, vr, ldvr,
ilo, ihi, scale, abnrm, rconde, rcondv, work, lwork, rwork, info)
```

Fortran 95:

```
call geevx(a, wr, wi [,vl] [,vr] [,balanc] [,ilo] [,ihi] [,scale] [,abnrm] [,
rconde] [,rcondv] [,info])

call geevx(a, w [,vl] [,vr] [,balanc] [,ilo] [,ihi] [,scale] [,abnrm] [,rconde]
[, rcondv] [,info])
```

Description

This routine computes for an n -by- n real/complex nonsymmetric matrix A , the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ilo , ihi , $scale$, and $abnrm$), reciprocal condition numbers for the eigenvalues ($rconde$), and reciprocal condition numbers for the right eigenvectors ($rcondv$).

The right eigenvector $v(j)$ of A satisfies

$$A \cdot v(j) = \lambda(j) \cdot v(j)$$

where $\lambda(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)^H A = \lambda(j) * u(j)^H$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$. The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * \text{inv}(D)$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see [LUG], Section 4.10.

Input Parameters

<i>balanc</i>	CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. If <i>balanc</i> = 'N', do not diagonally scale or permute; If <i>balanc</i> = 'P', perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; If <i>balanc</i> = 'S', diagonally scale the matrix, i.e. replace A by $D * A * \text{inv}(D)$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; If <i>balanc</i> = 'B', both diagonally scale and permute A. Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.
<i>jobvl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvl</i> = 'N', left eigenvectors of A are not computed; If <i>jobvl</i> = 'V', left eigenvectors of A are computed. If <i>sense</i> = 'E' or 'B', then <i>jobvl</i> must be 'V'.
<i>jobvr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvr</i> = 'N', right eigenvectors of A are not computed; If <i>jobvr</i> = 'V', right eigenvectors of A are computed. If <i>sense</i> = 'E' or 'B', then <i>jobvr</i> must be 'V'.

sense CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.
 If *sense* = 'N', none are computed;
 If *sense* = 'E', computed for eigenvalues only;
 If *sense* = 'V', computed for right eigenvectors only;
 If *sense* = 'B', computed for eigenvalues and right eigenvectors.
 If *sense* is 'E' or 'B', both left and right eigenvectors must also be computed (*jobvl* = 'V' and *jobvr* = 'V').

n INTEGER. The order of the matrix *A* ($n \geq 0$).

a, work REAL for *sgeevx*
 DOUBLE PRECISION for *dgeevx*
 COMPLEX for *cgeevx*
 DOUBLE COMPLEX for *zgeevx*.
 Arrays:
a(*lda*,*) is an array containing the *n*-by-*n* matrix *A*.
 The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*. Must be at least $\max(1, n)$.

ldvl, ldvr INTEGER. The leading dimensions of the output arrays *vl* and *vr*, respectively.
 Constraints:
 $ldvl \geq 1$; $ldvr \geq 1$.
 If *jobvl* = 'V', $ldvl \geq \max(1, n)$;
 If *jobvr* = 'V', $ldvr \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.
 For real flavors:
 If *sense* = 'N' or 'E', $lwork \geq \max(1, 2n)$, and if *jobvl* = 'V' or *jobvr* = 'V', $lwork \geq 3n$;
 If *sense* = 'V' or 'B', $lwork \geq n*(n+6)$.
 For good performance, *lwork* must generally be larger.
 For complex flavors:

If *sense* = 'N' or 'E', $lwork \geq \max(1, 2n)$;

If *sense* = 'V' or 'B', $lwork \geq n^2 + 2n$. For good performance, *lwork* must generally be larger.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork

REAL for *cgeevx*

DOUBLE PRECISION for *zgeevx*

Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

iwork

INTEGER.

Workspace array, DIMENSION at least $\max(1, 2n-2)$. Used in real flavors only. Not referenced if *sense* = 'N' or 'E'.

Output Parameters

a

On exit, this array is overwritten.

If *jobvl* = 'V' or *jobvr* = 'V', it contains the real-Schur/Schur form of the balanced version of the input matrix *A*.

wr, wi

REAL for *sgeevx*

DOUBLE PRECISION for *dgeevx*

Arrays, DIMENSION at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first.

w

COMPLEX for *cgeevx*

DOUBLE COMPLEX for *zgeevx*.

Array, DIMENSION at least $\max(1, n)$. Contains the computed eigenvalues.

vl, vr

REAL for *sgeevx*

DOUBLE PRECISION for *dgeevx*

COMPLEX for *cgeevx*

DOUBLE COMPLEX for *zgeevx*.

Arrays:

$vl(ldvl,*)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:, j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = vl(:, j) + i*vl(:, j+1)$ and $u(j+1) = vl(:, j) - i*vl(:, j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .

$vr(ldvr,*)$; the second dimension of vr must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i*vr(:, j+1)$ and $v(j+1) = vr(:, j) - i*vr(:, j+1)$, where $i = \sqrt{-1}$.

For complex flavors:

$v(j) = vr(:, j)$, the j -th column of vr .

ilo, ihi

INTEGER. *ilo* and *ihi* are integer values determined when A was balanced.

The balanced $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

scale

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

	Array, <code>DIMENSION</code> at least $\max(1, n)$. Details of the permutations and scaling factors applied when balancing <i>A</i>. If $P(j)$ is the index of the row and column interchanged with row and column j, and $D(j)$ is the scaling factor applied to row and column j, then $scale(j) = P(j)$, for $j = 1, \dots, ilo-1$ $= D(j)$, for $j = ilo, \dots, ihi$ $= P(j)$ for $j = ihi+1, \dots, n$. The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.
<i>abnrm</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).
<i>rconde, rcondv</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, <code>DIMENSION</code> at least $\max(1, n)$ each. <i>rconde(j)</i> is the reciprocal condition number of the j-th eigenvalue. <i>rcondv(j)</i> is the reciprocal condition number of the j-th right eigenvector.
<i>work(1)</i>	On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the required minimal size of <i>lwork</i>.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>th parameter had an illegal value. If <i>info</i> = <i>i</i>, the <i>QR</i> algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:<i>ilo</i>-1 and <i>i</i>+1:<i>n</i> of <i>wr</i> and <i>wi</i> (for real flavors) or <i>w</i> (for complex flavors) contain eigenvalues which have converged.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geevx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>wr</i>	Holds the vector of length (n) . Used in real flavors only.
<i>wi</i>	Holds the vector of length (n) . Used in real flavors only.
<i>w</i>	Holds the vector of length (n) . Used in complex flavors only.
<i>vl</i>	Holds the matrix <i>VL</i> of size (n, n) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, n) .
<i>scale</i>	Holds the vector of length (n) .
<i>rconde</i>	Holds the vector of length (n) .
<i>rcondv</i>	Holds the vector of length (n) .
<i>balanc</i>	Must be 'N', 'B', 'P' or 'S'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.
<i>sense</i>	Restored based on the presence of arguments <i>rconde</i> and <i>rcondv</i> as follows: <i>sense</i> = 'B', if both <i>rconde</i> and <i>rcondv</i> are present, <i>sense</i> = 'E', if <i>rconde</i> is present and <i>rcondv</i> omitted, <i>sense</i> = 'V', if <i>rconde</i> is omitted and <i>rcondv</i> present, <i>sense</i> = 'N', if both <i>rconde</i> and <i>rcondv</i> are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Singular Value Decomposition

This section describes LAPACK driver routines used for solving singular value problems. See also computational routines [computational routines](#) that can be called to solve these problems. [Table 4-12](#) lists all such driver routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-12 Driver Routines for Singular Value Decomposition

Routine Name	Operation performed
?gesvd	Computes the singular value decomposition of a general rectangular matrix.
?gesdd	Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.
?ggsvd	Computes the generalized singular value decomposition of a pair of general rectangular matrices.

?gesvd

Computes the singular value decomposition of a general rectangular matrix.

Syntax

FORTRAN 77:

```
call sgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, info)
call dgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, info)
call cgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, info)
call zgesvd(jobu, jobvt, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, info)
```

Fortran 95:

```
call gesvd(a, s [,u] [,vt] [,ww] [,job] [,info])
```

Description

This routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^H$$

where Σ is an m -by- n matrix which is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns V^H , not V .

Input Parameters

<i>jobu</i>	CHARACTER*1. Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix U. If <i>jobu</i> = 'A', all m columns of U are returned in the array <i>u</i>; if <i>jobu</i> = 'S', the first $\min(m, n)$ columns of U (the left singular vectors) are returned in the array <i>u</i>; if <i>jobu</i> = 'O', the first $\min(m, n)$ columns of U (the left singular vectors) are overwritten on the array <i>a</i>; if <i>jobu</i> = 'N', no columns of U (no left singular vectors) are computed.
<i>jobvt</i>	CHARACTER*1. Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix V^H. If <i>jobvt</i> = 'A', all n rows of V^H are returned in the array <i>vt</i>; if <i>jobvt</i> = 'S', the first $\min(m, n)$ rows of V^H (the right singular vectors) are returned in the array <i>vt</i>; if <i>jobvt</i> = 'O', the first $\min(m, n)$ rows of V^H (the right singular vectors) are overwritten on the array <i>a</i>; if <i>jobvt</i> = 'N', no rows of V^H (no right singular vectors) are computed. <i>jobvt</i> and <i>jobu</i> cannot both be 'O'.
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).

<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a, work</i>	REAL for sgesvd DOUBLE PRECISION for dgesvd COMPLEX for cgesvd DOUBLE COMPLEX for zgesvd. Arrays: <i>a(lda,*)</i> is an array containing the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, m)$.
<i>ldu, ldvt</i>	INTEGER. The leading dimensions of the output arrays <i>u</i> and <i>vt</i> , respectively. Constraints: $ldu \geq 1; ldvt < 1$. If <i>jobu</i> = 'S' or 'A', $ldu \geq m$; If <i>jobvt</i> = 'A', $ldvt \geq n$; If <i>jobvt</i> = 'S', $ldvt \geq \min(m, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> ; $lwork \geq 1$. Constraints: $lwork \geq \max(3 * \min(m, n) + \max(m, n), 5 * \min(m, n))$ (for real flavors); $lwork \geq 2 * \min(m, n) + \max(m, n)$ (for complex flavors). For good performance, <i>lwork</i> must generally be larger. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for details.
<i>rwork</i>	REAL for cgesvd DOUBLE PRECISION for zgesvd Workspace array, DIMENSION at least $\max(1, 5 * \min(m, n))$. Used in complex flavors only.

Output Parameters

<i>a</i>	On exit, If <i>jobu</i> = 'O', <i>a</i> is overwritten with the first $\min(m, n)$ columns of U (the left singular vectors, stored columnwise); If <i>jobvt</i> = 'O', <i>a</i> is overwritten with the first $\min(m, n)$ rows of V^H (the right singular vectors, stored rowwise); If <i>jobu</i> ≠ 'O' and <i>jobvt</i> ≠ 'O', the contents of <i>a</i> are destroyed.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the singular values of <i>A</i> sorted so that $s(i) < s(i+1)$.
<i>u, vt</i>	REAL for sgesvd DOUBLE PRECISION for dgesvd COMPLEX for cgesvd DOUBLE COMPLEX for zgesvd. Arrays: <i>u</i>(<i>ldu</i>,*); the second dimension of <i>u</i> must be at least $\max(1, m)$ if <i>jobu</i> = 'A', and at least $\max(1, \min(m, n))$ if <i>jobu</i> = 'S'. If <i>jobu</i> = 'A', <i>u</i> contains the m-by-m orthogonal/unitary matrix U. If <i>jobu</i> = 'S', <i>u</i> contains the first $\min(m, n)$ columns of U (the left singular vectors, stored columnwise). If <i>jobu</i> = 'N' or 'O', <i>u</i> is not referenced. <i>vt</i>(<i>ldvt</i>,*); the second dimension of <i>vt</i> must be at least $\max(1, n)$. If <i>jobvt</i> = 'A', <i>vt</i> contains the n-by-n orthogonal/unitary matrix V_H. If <i>jobvt</i> = 'S', <i>vt</i> contains the first $\min(m, n)$ rows of V^H (the right singular vectors, stored rowwise). If <i>jobvt</i> = 'N' or 'O', <i>vt</i> is not referenced.
<i>work</i>	On exit, if <i>info</i> = 0, then <i>work</i>(1) returns the required minimal size of <i>lwork</i>. For real flavors:

	If $info > 0$, $work(2:\min(m, n))$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = u * B * vt$, so it has the same singular values as A, and singular vectors related by u and vt.
<i>rwork</i>	On exit (for complex flavors), if $info > 0$, $rwork(1:\min(m, n)-1)$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = u * B * vt$, so it has the same singular values as A, and singular vectors related by u and vt.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value. If $info = i$, then if <code>?bdsqr</code> did not converge, i specifies how many superdiagonals of the intermediate bidiagonal form B did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesvd` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>s</i>	Holds the vector of length $\min(m, n)$.
<i>u</i>	Holds the matrix U of size $(m, \min(m, n))$.
<i>vt</i>	Holds the matrix VT of size $(\min(m, n), n)$.
<i>ww</i>	Holds the vector of length $\min(m, n)-1$. <i>ww</i> contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in s (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A , and singular vectors related by U and VT .
<i>job</i>	Must be either 'N', or 'U', or 'V'. The default value is 'N'. If <i>job</i> = 'U', and <i>u</i> is not present, then <i>u</i> is returned in the array <i>a</i>. If <i>job</i> = 'V', and <i>vt</i> is not present, then <i>vt</i> is returned in the array <i>a</i>.

<i>jobu</i>	Restored based on the presence of the argument <i>u</i>, value of <i>job</i> and sizes of arrays <i>u</i> and <i>a</i> as follows: <i>jobu</i> = 'A', if <i>u</i> is present and the number of columns in <i>u</i> is equal to the number of rows in <i>a</i>, <i>jobu</i> = 'S', if <i>u</i> is present and the number of columns in <i>u</i> is not equal to the number of rows in <i>a</i>, <i>jobu</i> = 'O', if <i>u</i> is not present and <i>job</i> is equal to 'U', <i>jobu</i> = 'N', if <i>u</i> is not present and <i>job</i> is not equal to 'U'.
<i>jobvt</i>	Restored based on the presence of the argument <i>vt</i>, value of <i>job</i> and sizes of arrays <i>vt</i> and <i>a</i> as follows: <i>jobvt</i> = 'A', if <i>vt</i> is present and the number of columns in <i>vt</i> is equal to the number of rows in <i>a</i>, <i>jobvt</i> = 'S', if <i>vt</i> is present and the number of columns in <i>vt</i> is not equal to the number of rows in <i>a</i>, <i>jobvt</i> = 'O', if <i>vt</i> is not present and <i>job</i> is equal to 'V', <i>jobvt</i> = 'N', if <i>vt</i> is not present and <i>job</i> is not equal to 'V',

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gesdd

Computes the singular value decomposition of a general rectangular matrix using a divide and conquer method.

Syntax

FORTRAN 77:

```
call sgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, iwork, info)
call dgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, iwork, info)
call cgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, iwork, info)
call zgesdd(jobz, m, n, a, lda, s, u, ldu, vt, ldvt, work, lwork, rwork, iwork, info)
```

Fortran 95:

```
call gesdd(a, s [,u] [,vt] [,jobz] [,info])
```

Description

This routine computes the singular value decomposition (SVD) of a real/complex m -by- n matrix A , optionally computing the left and/or right singular vectors.

If singular vectors are desired, it uses a divide and conquer algorithm. The SVD is written

$$A = U \Sigma V^H,$$

where Σ is an m -by- n matrix which is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal/unitary matrix, and V is an n -by- n orthogonal/unitary matrix. The diagonal elements of Σ are the singular values of A ; they are real and non-negative, and are returned in descending order. The first $\min(m, n)$ columns of U and V are the left and right singular vectors of A .

Note that the routine returns V^H , not V .

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'A', 'S', 'O', or 'N'. Specifies options for computing all or part of the matrix U .

If $jobz = 'A'$, all m columns of U and all n rows of V^T are returned in the arrays u and vt ;
 if $jobz = 'S'$, the first $\min(m, n)$ columns of U and the first $\min(m, n)$ rows of V^T are returned in the arrays u and vt ;
 if $jobz = 'O'$, then
 if $m \geq n$, the first n columns of U are overwritten in the array a and all rows of V^T are returned in the array vt ;
 if $m < n$, all columns of U are returned in the array u and the first m rows of V^T are overwritten in the array a ;
 if $jobz = 'N'$, no columns of U or rows of V^T are computed.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for sgesdd
 DOUBLE PRECISION for dgesdd
 COMPLEX for cgesdd
 DOUBLE COMPLEX for zgesdd.
 Arrays: $a(lda,*)$ is an array containing the m -by- n matrix A .
 The second dimension of a must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array a . Must be at least $\max(1, m)$.

$ldu, ldvt$ INTEGER. The leading dimensions of the output arrays u and vt , respectively.
 Constraints:
 $ldu \geq 1; ldvt \geq 1$.
 If $jobz = 'S'$ or $'A'$, or $jobz = 'O'$ and $m < n$,
 then $ldu \geq m$;
 If $jobz = 'A'$ or $jobz = 'O'$ and $m < n$,
 then $ldvt \geq n$;
 If $jobz = 'S'$, $ldvt \geq \min(m, n)$.

$lwork$ INTEGER.
 The dimension of the array $work$; $lwork \geq 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the $work(1)$, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$rwork$

REAL for cgesdd

DOUBLE PRECISION for zgesdd

Workspace array, DIMENSION at least $\max(1, 5 \cdot \min(m, n))$ if $jobz = 'N'$.

Otherwise, the dimension of $rwork$ must be at least $\max(1, 5 \cdot (\min(m, n))^2 + 7 \cdot \min(m, n))$. This array is used in complex flavors only.

$iwork$

INTEGER. Workspace array, DIMENSION at least $\max(1, 8 \cdot \min(m, n))$.

Output Parameters

a

On exit:

If $jobz = 'O'$, then if $m \geq n$, a is overwritten with the first n columns of U (the left singular vectors, stored columnwise). If $m < n$, a is overwritten with the first m rows of V^T (the right singular vectors, stored rowwise);

If $jobz \neq 'O'$, the contents of a are destroyed.

s

REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the singular values of A sorted so that $s(i) \geq s(i+1)$.

u, vt

REAL for sgesdd

DOUBLE PRECISION for dgesdd

COMPLEX for cgesdd

DOUBLE COMPLEX for zgesdd.

Arrays:

$u(1du,*)$; the second dimension of u must be at least $\max(1, m)$ if $jobz = 'A'$ or $jobz = 'O'$ and $m < n$.

If $jobz = 'S'$, the second dimension of u must be at least $\max(1, \min(m, n))$.

If $jobz = 'A'$ or $jobz = 'O'$ and $m < n$, u contains the m -by- m orthogonal/unitary matrix U .
 If $jobz = 'S'$, u contains the first $\min(m, n)$ columns of U (the left singular vectors, stored columnwise).
 If $jobz = 'O'$ and $m \geq n$, or $jobz = 'N'$, u is not referenced.
 $vt(ldvt,*)$; the second dimension of vt must be at least $\max(1, n)$.
 If $jobz = 'A'$ or $jobz = 'O'$ and $m \geq n$, vt contains the n -by- n orthogonal/unitary matrix V^T .
 If $jobz = 'S'$, vt contains the first $\min(m, n)$ rows of V^T (the right singular vectors, stored rowwise).
 If $jobz = 'O'$ and $m < n$, or $jobz = 'N'$, vt is not referenced.

$work(1)$ On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, then $?bdsdc$ did not converge, updating process failed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesdd` interface are the following:

a	Holds the matrix A of size (m, n) .
s	Holds the vector of length $\min(m, n)$.
u	Holds the matrix U of size $(m, \min(m, n))$.
vt	Holds the matrix V^T of size $(\min(m, n), n)$.
job	Must be 'N', 'A', 'S', or 'O'. The default value is 'N'.

Application Notes

For real flavors:

If $jobz = 'N'$, $lwork \geq 3 * \min(m, n) + \max(\max(m, n), 6 * \min(m, n))$;

If $jobz = 'O'$, $lwork \geq 3 * (\min(m, n))^2 + \max(\max(m, n), 5 * (\min(m, n))^2 + 4 * \min(m, n))$;

If $jobz = 'S'$ or $'A'$, $lwork \geq 3 * (\min(m, n))^2 + \max(\max(m, n), 4 * (\min(m, n))^2 + 4 * \min(m, n))$

For complex flavors:

If $jobz = 'N'$, $lwork \geq 2 * \min(m, n) + \max(m, n)$;

If $jobz = 'O'$, $lwork \geq 2 * (\min(m, n))^2 + \max(m, n) + 2 * \min(m, n)$;

If $jobz = 'S'$ or $'A'$, $lwork \geq (\min(m, n))^2 + \max(m, n) + 2 * \min(m, n)$;

For good performance, $lwork$ should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggsvd

Computes the generalized singular value decomposition of a pair of general rectangular matrices.

Syntax

FORTRAN 77:

```
call sggsvd(jobu, jobv, jobq, m, n, p, k, l, a, lda, b, ldb, alpha, beta, u,
ldu, v, ldv, q, ldq, work, iwork, info)

call dggsvd(jobu, jobv, jobq, m, n, p, k, l, a, lda, b, ldb, alpha, beta, u,
ldu, v, ldv, q, ldq, work, iwork, info)

call cggsvd(jobu, jobv, jobq, m, n, p, k, l, a, lda, b, ldb, alpha, beta, u,
ldu, v, ldv, q, ldq, work, rwork, iwork, info)

call zggsvd(jobu, jobv, jobq, m, n, p, k, l, a, lda, b, ldb, alpha, beta, u,
ldu, v, ldv, q, ldq, work, rwork, iwork, info)
```

Fortran 95:

```
call ggsvd(a, b, alpha, beta [, k] [,l] [,u] [,v] [,q] [,iwork] [,info])
```

Description

This routine computes the generalized singular value decomposition (GSVD) of an m -by- n real/complex matrix A and p -by- n real/complex matrix B :

$$U^H A Q = D_1 \begin{pmatrix} I & R \end{pmatrix}, \quad V^H B Q = D_2 \begin{pmatrix} I & R \end{pmatrix},$$

where U , V and Q are orthogonal/unitary matrices.

Let $k+1$ = the effective numerical rank of the matrix $(A^H, B^H)^H$, then R is a $(k+1)$ -by- $(k+1)$ nonsingular upper triangular matrix, D_1 and D_2 are m -by- $(k+1)$ and p -by- $(k+1)$ "diagonal" matrices and of the following structures, respectively:

If $m-k-1 \geq 0$,

$$D_1 = \begin{matrix} & k & 1 \\ & \begin{pmatrix} I & 0 \\ 0 & C \end{pmatrix} \\ m - k - 1 & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & k & 1 \\ p - 1 & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} n - k - 1 & k & 1 \\ \begin{pmatrix} 0 & R_{11} & R_{12} \\ 0 & 0 & R_{22} \end{pmatrix} \end{matrix},$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(K+1))$

$S = \text{diag}(\beta(K+1), \dots, \beta(K+1))$

$C^2 + S^2 = I$

R is stored in $a(1:k+1, n-k-1+1:n)$ on exit.

If $m-k-1 < 0$,

$$D_1 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D_2 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \begin{pmatrix} 0 & S & 0 \\ & 0 & I \end{pmatrix} \\ p-l & \begin{pmatrix} 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$(0 \ R) = \begin{matrix} & n-k-l & k & m-k & k+l-m \\ & k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \\ 0 & 0 & R_{22} & R_{23} \\ 0 & 0 & 0 & R_{33} \end{pmatrix} \end{matrix}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(m)),$

$S = \text{diag}(\beta(K+1), \dots, \beta(m)),$

$C_2 + S_2 = I$

On exit, $\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \end{pmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The routine computes C , S , R , and optionally the orthogonal/unitary transformation matrices U , V and Q .

In particular, if B is an n -by- n nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A^*B^{-1} :

$$A^*B^{-1} = U^* (D_1 \ D_2^{-1}) * V^H.$$

If $(A^H, B^H)^H$ has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B . Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A^H * A * X = \lambda * B^H * B * X.$$

Input Parameters

<i>jobu</i>	CHARACTER*1. Must be 'U' or 'N'. If <i>jobu</i> = 'U', orthogonal/unitary matrix U is computed. If <i>jobu</i> = 'N', U is not computed.
<i>jobv</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>jobv</i> = 'V', orthogonal/unitary matrix V is computed. If <i>jobv</i> = 'N', V is not computed.
<i>jobq</i>	CHARACTER*1. Must be 'Q' or 'N'. If <i>jobq</i> = 'Q', orthogonal/unitary matrix Q is computed. If <i>jobq</i> = 'N', Q is not computed.
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
<i>p</i>	INTEGER. The number of rows of the matrix B ($p \geq 0$).
<i>a, b, work</i>	REAL for sggsvd DOUBLE PRECISION for dggsvd COMPLEX for cggsvd DOUBLE COMPLEX for zggsvd. Arrays: <i>a(lda,*)</i> contains the m -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b(lb,*)</i> contains the p -by- n matrix B . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $\max(3n, m, p) + n$.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, p)$.
<i>ldu</i>	INTEGER. The first dimension of the array <i>u</i> . $ldu \geq \max(1, m)$ if <i>jobu</i> = 'U'; $ldu \geq 1$ otherwise.
<i>ldv</i>	INTEGER. The first dimension of the array <i>v</i> . $ldv \geq \max(1, p)$ if <i>jobv</i> = 'V'; $ldv \geq 1$ otherwise.
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> . $ldq \geq \max(1, n)$ if <i>jobq</i> = 'Q'; $ldq \geq 1$ otherwise.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cggsvd DOUBLE PRECISION for zggsvd. Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>k, l</i>	INTEGER. On exit, <i>k</i> and <i>l</i> specify the dimension of the subblocks. The sum $k+l$ is equal to the effective numerical rank of $(A^H, B^H)^H$.
<i>a</i>	On exit, <i>a</i> contains the triangular matrix <i>R</i> or part of <i>R</i> .
<i>b</i>	On exit, <i>b</i> contains part of the triangular matrix <i>R</i> if $m-k-l < 0$.
<i>alpha, beta</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays, DIMENSION at least $\max(1, n)$ each. Contain the generalized singular value pairs of <i>A</i> and <i>B</i> : $\alpha(1:k) = 1$, $\beta(1:k) = 0$, and if $m-k-l \geq 0$, $\alpha(k+1:k+l) = C$, $\beta(k+1:k+l) = S$, or if $m-k-l < 0$, $\alpha(k+1:m) = C$, $\alpha(m+1:k+l) = 0$ $\beta(k+1:m) = S$, $\beta(m+1:k+l) = 1$ and

<i>u, v, q</i>	<pre> alpha(k+l+1:n) = 0 beta(k+l+1:n) = 0. REAL for sggsvd DOUBLE PRECISION for dggsvd COMPLEX for cggsvd DOUBLE COMPLEX for zggsvd. Arrays: <i>u(ldu,*)</i>; the second dimension of <i>u</i> must be at least max(1, <i>m</i>). If <i>jobu</i> = 'U', <i>u</i> contains the <i>m</i>-by-<i>m</i> orthogonal/unitary matrix <i>U</i>. If <i>jobu</i> = 'N', <i>u</i> is not referenced. <i>v(ldv,*)</i>; the second dimension of <i>v</i> must be at least max(1, <i>p</i>). If <i>jobv</i> = 'V', <i>v</i> contains the <i>p</i>-by-<i>p</i> orthogonal/unitary matrix <i>V</i>. If <i>jobv</i> = 'N', <i>v</i> is not referenced. <i>q(ldq,*)</i>; the second dimension of <i>q</i> must be at least max(1, <i>n</i>). If <i>jobq</i> = 'Q', <i>q</i> contains the <i>n</i>-by-<i>n</i> orthogonal/unitary matrix <i>Q</i>. If <i>jobq</i> = 'N', <i>q</i> is not referenced. <i>iwork</i> On exit, <i>iwork</i> stores the sorting information. <i>info</i> INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine ?tgsja. </pre>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggsvd` interface are the following:

<i>a</i> <i>b</i>	Holds the matrix <i>A</i> of size (<i>m</i>, <i>n</i>). Holds the matrix <i>B</i> of size (<i>p</i>, <i>n</i>).

<i>alpha</i>	Holds the vector of length (<i>n</i>).
<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>u</i>	Holds the matrix <i>U</i> of size (<i>m</i> , <i>m</i>).
<i>v</i>	Holds the matrix <i>V</i> of size (<i>p</i> , <i>p</i>).
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>iwork</i>	Holds the vector of length (<i>n</i>).
<i>jobu</i>	Restored based on the presence of the argument <i>u</i> as follows: <i>jobu</i> = 'U', if <i>u</i> is present, <i>jobu</i> = 'N', if <i>u</i> is omitted.
<i>jobv</i>	Restored based on the presence of the argument <i>v</i> as follows: <i>jobz</i> = 'V', if <i>v</i> is present, <i>jobz</i> = 'N', if <i>v</i> is omitted.
<i>jobq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>jobz</i> = 'Q', if <i>q</i> is present, <i>jobz</i> = 'N', if <i>q</i> is omitted.

Generalized Symmetric Definite Eigenproblems

This section describes LAPACK driver routines used for solving generalized symmetric definite eigenproblems. See also [computational routines](#) that can be called to solve these problems. [Table 4-13](#) lists all such driver routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-13 Driver Routines for Solving Generalized Symmetric Definite Eigenproblems

Routine Name	Operation performed
?sygv/?hegv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem.
?sygvd/?hegvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.
?sygvx/?hegvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem.
?spgv/?hpgv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem with matrices in packed storage.

Routine Name	Operation performed
?spgvd/?hpgvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.
?spgvx/?hpgvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem with matrices in packed storage.
?sbgv/?hbgv	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem with banded matrices.
?sbgvd/?hbgvd	Computes all eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.
?sbgvx/?hbgvx	Computes selected eigenvalues and, optionally, eigenvectors of a real / complex generalized symmetric /Hermitian definite eigenproblem with banded matrices.

?sygv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

FORTRAN 77:

```
call ssygv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, info)
call dsygv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, info)
```

Fortran 95:

```
call sygv(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B.
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for ssygv DOUBLE PRECISION for dsygv. Arrays: <i>a</i>(<i>lda</i>,*) contains the upper or lower triangle of the symmetric matrix A, as specified by <i>uplo</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i>(<i>ldb</i>,*) contains the upper or lower triangle of the symmetric positive definite matrix B, as specified by <i>uplo</i>. The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i>; at least $\max(1, n)$.

lwork INTEGER.
The dimension of the array *work*;
 $lwork \geq \max(1, 3n-1)$.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:
if *itype* = 1 or 2, $Z^T * B * Z = I$;
if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;
If *jobz* = 'N', then on exit the upper triangle (if *uplo* = 'U') or the lower triangle (if *uplo* = 'L') of *A*, including the diagonal, is destroyed.

b On exit, if *info* ≤ *n*, the part of *b* containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.

w REAL for ssygv
DOUBLE PRECISION for dsygv.
Array, DIMENSION at least max(1, *n*).
If *info* = 0, contains the eigenvalues in ascending order.

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th argument had an illegal value.
If *info* > 0, spotrf/dpotrf and ssyev/dsyev returned an error code:
If *info* = *i* ≤ *n*, ssyev/dsyev failed to converge, and *i* off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sygv` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>w</code>	Holds the vector of length (n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>jobz</code>	Must be 'N' or 'V'. The default value is 'N'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use $lwork \geq (nb+2)*n$, where nb is the blocksize for `ssytrd/dsytrd` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work, iwork$) on exit. Use this value ($work(1), iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if $work$ ($liwork$) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem.

Syntax

FORTRAN 77:

```
call chegv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, info)
call zhegv(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork, info)
```

Fortran 95:

```
call hegv(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian and B is also positive definite.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B .

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

a, *b*, *work* COMPLEX for chegv
DOUBLE COMPLEX for zhegv.

Arrays:
a(*lda*,*) contains the upper or lower triangle of the Hermitian matrix *A*, as specified by *uplo*.
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) contains the upper or lower triangle of the Hermitian positive definite matrix *B*, as specified by *uplo*.
 The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*; $lwork \geq \max(1, 2n-1)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
 See *Application Notes* for the suggested value of *lwork*.

rwork REAL for chegv
DOUBLE PRECISION for zhegv.
 Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

a On exit, if *jobz* = 'V', then if *info* = 0, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:
 if *itype* = 1 or 2, $Z^H * B * Z = I$;
 if *itype* = 3, $Z^H * \text{inv}(B) * Z = I$;
 If *jobz* = 'N', then on exit the upper triangle (if *uplo* = 'U') or the lower triangle (if *uplo* = 'L') of *A*, including the diagonal, is destroyed.

<i>b</i>	On exit, if <i>info</i> ≤ <i>n</i> , the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.
<i>w</i>	REAL for chegv DOUBLE PRECISION for zhegv. Array, DIMENSION at least max(1, <i>n</i>). If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument has an illegal value. If <i>info</i> > 0, cpotrf/zpotrf and cheev/zheev return an error code: If <i>info</i> = <i>i</i> ≤ <i>n</i> , cheev/zheev fails to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal do not converge to zero; If <i>info</i> = <i>n</i> + <i>i</i> , for 1 ≤ <i>i</i> ≤ <i>n</i> , then the leading minor of order <i>i</i> of <i>B</i> is not positive-definite. The factorization of <i>B</i> can not be completed and no eigenvalues or eigenvectors are computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegv` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where nb is the blocksize for `chetrd/zhetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sygvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call ssygvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, iwork,
liwork, info)

call dsygvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, iwork,
liwork, info)
```

Fortran 95:

```
call sygvd(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be symmetric and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a, b, work</i>	REAL for ssygvd DOUBLE PRECISION for dsygvd. Arrays: <i>a</i> (<i>lda</i> ,*) contains the upper or lower triangle of the symmetric matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the upper or lower triangle of the symmetric positive definite matrix B , as specified by <i>uplo</i> . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.

lwork

INTEGER.

The dimension of the array *work*.

Constraints:

If $n \leq 1$, $lwork \geq 1$;If $jobz = 'N'$ and $n > 1$, $lwork < 2n+1$;If $jobz = 'V'$ and $n > 1$, $lwork < 2n^2+6n+1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, its dimension $\max(1, lwork)$.*liwork*

INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

a

On exit, if $jobz = 'V'$, then if $info = 0$, *a* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^T * B * Z = I$;if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of *A*, including the diagonal, is destroyed.

<i>b</i>	On exit, if <i>info</i> ≤ <i>n</i> , the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.
<i>w</i>	REAL for ssygvd DOUBLE PRECISION for dsygvd. Array, DIMENSION at least max(1, <i>n</i>). If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0 = <i>i</i> ≤ <i>n</i> , and <i>jobz</i> = 'N', then the algorithm failed to converge; <i>i</i> off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if <i>jobz</i> = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>info</i> /(<i>n</i> +1) through mod(<i>info</i> , <i>n</i> +1); If <i>info</i> > 0 = <i>n</i> + <i>i</i> , for 1 ≤ <i>i</i> ≤ <i>n</i> , then the leading minor of order <i>i</i> of <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sygvd* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.

`jobz` Must be 'N' or 'V'. The default value is 'N'.
`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If `lwork` (or `liwork`) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`) on exit. Use this value (`work(1)`, `iwork(1)`) for subsequent runs.

If `lwork = -1` (`liwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`). This operation is called a workspace query.

Note that if `work` (`liwork`) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chegvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork,
lrwork, iwork, liwork, info)
```

```
call zhegvd(itype, jobz, uplo, n, a, lda, b, ldb, w, work, lwork, rwork,
lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hegvd(a, b, w [,itype] [,jobz] [,uplo] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of A and B; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of A and B.
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>a, b, work</i>	COMPLEX for <code>chegvd</code> DOUBLE COMPLEX for <code>zhegvd</code>. Arrays: <i>a</i>(<i>lda</i>,*) contains the upper or lower triangle of the Hermitian matrix A, as specified by <i>uplo</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i>(<i>ldb</i>,*) contains the upper or lower triangle of the Hermitian positive definite matrix B, as specified by <i>uplo</i>. The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i>; at least $\max(1, n)$.

lwork INTEGER.
The dimension of the array *work*.
Constraints:
If $n \leq 1$, $lwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $lwork \geq n+1$;
If $jobz = 'V'$ and $n > 1$, $lwork \geq n^2+2n$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork REAL for `chegvd`
DOUBLE PRECISION for `zhegvd`.
Workspace array, DIMENSION $\max(1, lrwork)$.

lrwork INTEGER.
The dimension of the array *rwork*.
Constraints:
If $n \leq 1$, $lrwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;
If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2+5n+1$.
If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.
Workspace array, DIMENSION $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*.
Constraints:
If $n \leq 1$, $liwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If `jobz = 'V'` and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the `work`, `rwork` and `iwork` arrays, returns these values as the first entries of the `work`, `rwork` and `iwork` arrays, and no error message related to `lwork` or `lrwork` or `liwork` is issued by `xerbla`. See *Application Notes* for details.

Output Parameters

<code>a</code>	On exit, if <code>jobz = 'V'</code> , then if <code>info = 0</code> , <code>a</code> contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if <code>itype = 1</code> or <code>2</code> , $Z^H * B * Z = I$; if <code>itype = 3</code> , $Z^H * \text{inv}(B) * Z = I$; If <code>jobz = 'N'</code> , then on exit the upper triangle (if <code>uplo = 'U'</code>) or the lower triangle (if <code>uplo = 'L'</code>) of A , including the diagonal, is destroyed.
<code>b</code>	On exit, if $info \leq n$, the part of <code>b</code> containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.
<code>w</code>	REAL for <code>chegvd</code> DOUBLE PRECISION for <code>zhegvd</code> . Array, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order.
<code>work(1)</code>	On exit, if $info = 0$, then <code>work(1)</code> returns the required minimal size of <code>lwork</code> .
<code>rwork(1)</code>	On exit, if $info = 0$, then <code>rwork(1)</code> returns the required minimal size of <code>lrwork</code> .
<code>iwork(1)</code>	On exit, if $info = 0$, then <code>iwork(1)</code> returns the required minimal size of <code>liwork</code> .
<code>info</code>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th argument had an illegal value.

If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;
 if $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $mod(info, n+1)$.
 If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegvd` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>w</code>	Holds the vector of length (n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>jobz</code>	Must be 'N' or 'V'. The default value is 'N'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of `lwork` (`liwork` or `lrwork`) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible `lwork` (`liwork` or `lrwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

FORTRAN 77:

```
call ssygvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu,
abstol, m, w, z, ldz, work, lwork, iwork, ifail, info)

call dsygvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu,
abstol, m, w, z, ldz, work, lwork, iwork, ifail, info)
```

Fortran 95:

```
call sygvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here *A* and *B* are assumed to be symmetric and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'.

If *jobz* = 'N', then compute eigenvalues only.
 If *jobz* = 'V', then compute eigenvalues and eigenvectors.

range CHARACTER*1. Must be 'A' or 'V' or 'I'.
 If *range* = 'A', the routine computes all eigenvalues.
 If *range* = 'V', the routine computes eigenvalues *lambda*(*i*) in the half-open interval:
 $vl < \lambda(i) \leq vu$.
 If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', arrays *a* and *b* store the upper triangles of *A* and *B*;
 If *uplo* = 'L', arrays *a* and *b* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

a, b, work REAL for ssygvx
 DOUBLE PRECISION for dsygvx.
 Arrays:
a(*lda*,*) contains the upper or lower triangle of the symmetric matrix *A*, as specified by *uplo*.
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) contains the upper or lower triangle of the symmetric positive definite matrix *B*, as specified by *uplo*.
 The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

vl, vu REAL for ssygvx
 DOUBLE PRECISION for dsygvx.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

	Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If $range = 'A'$ or $'V'$, il and iu are not referenced.
<i>abstol</i>	REAL for ssygvx DOUBLE PRECISION for dsygvx. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. Constraints: $ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>; $lwork < \max(1, 8n)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>a</i>	On exit, the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of <i>A</i> , including the diagonal, is overwritten.
<i>b</i>	On exit, if $info \leq n$, the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$.
<i>w, z</i>	REAL for ssygvx DOUBLE PRECISION for dsygvx. Arrays: <i>w</i>(*), DIMENSION at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^T B Z = I$;

if $itype = 3$, $Z^T \text{inv}(B) Z = I$;

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$work(1)$

On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i th argument had an illegal value.

If $info > 0$, $spotrf/dpotrf$ and $ssyevx/dsyevx$ returned an error code:

If $info = i \leq n$, $ssyevx/dsyevx$ failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array $ifail$;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sygvx` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>w</code>	Holds the vector of length (n) .
<code>z</code>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<code>ifail</code>	Holds the vector of length (n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>vl</code>	Default value for this element is $vl = -HUGE(vl)$.
<code>vu</code>	Default value for this element is $vu = HUGE(vl)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this element is $abstol = 0.0\_WP$.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <code>ifail</code> is present and z is omitted.
<code>range</code>	Restored based on the presence of arguments vl , vu , il , iu as follows: $range = 'V'$, if one of or both vl and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of vl , vu , il , iu is present, Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * ||T||_1$ is used as tolerance, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, set $abstol$ to $2 * \text{lamch}('S')$.

For optimum performance use $lwork \geq (nb+3)*n$, where nb is the blocksize for `ssytrd/dsytrd` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem.

Syntax

FORTRAN 77:

```
call chegvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu,
abstol, m, w, z, ldz, work, lwork, rwork, iwork, ifail, info)
```

```
call zhegvx(itype, jobz, range, uplo, n, a, lda, b, ldb, vl, vu, il, iu,
abstol, m, w, z, ldz, work, lwork, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hegvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, \quad A^*B^*x = \lambda^*x, \quad \text{or} \quad B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.
 If *range* = 'V', the routine computes eigenvalues *lambda(i)* in the half-open interval:
 $vl < \lambda(i) \leq vu$.
 If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', arrays *a* and *b* store the upper triangles of *A* and *B*;
 If *uplo* = 'L', arrays *a* and *b* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

a, b, work COMPLEX for *chegvx*
 DOUBLE COMPLEX for *zhegvx*.
Arrays:
a(lda,)* contains the upper or lower triangle of the Hermitian matrix *A*, as specified by *uplo*.
 The second dimension of *a* must be at least $\max(1, n)$.
b(ldb,)* contains the upper or lower triangle of the Hermitian positive definite matrix *B*, as specified by *uplo*.
 The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

vl, vu REAL for *chegvx*
 DOUBLE PRECISION for *zhegvx*.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.

	If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for chegvx DOUBLE PRECISION for zhegvx. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . Constraints: $ldz \geq 1$; if <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> ; $lwork \geq \max(1, 2n)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for chegvx DOUBLE PRECISION for zhegvx. Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>a</i>	On exit, the upper triangle (if <i>uplo</i> = 'U') or the lower triangle (if <i>uplo</i> = 'L') of <i>A</i> , including the diagonal, is overwritten.
<i>b</i>	On exit, if <i>info</i> ≤ <i>n</i> , the part of <i>b</i> containing the matrix is overwritten by the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.
<i>w</i>	REAL for chegvx DOUBLE PRECISION for zhegvx. Array, DIMENSION at least $\max(1, n)$.

The first m elements of w contain the selected eigenvalues in ascending order.

z
 COMPLEX for chegvx
 DOUBLE COMPLEX for zhegvx.
 Array $z(ldz,*)$. The second dimension of z must be at least $\max(1, m)$.
 If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized as follows:
 if $itype = 1$ or 2 , $Z^H * B * Z = I$;
 if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;
 If $jobz = 'N'$, then z is not referenced.
 If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.
 Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

$work(1)$
 On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.

$ifail$
 INTEGER.
 Array, DIMENSION at least $\max(1, n)$.
 If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.
 If $jobz = 'N'$, then $ifail$ is not referenced.

$info$
 INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i th argument had an illegal value.
 If $info > 0$, cpotrf/zpotrf and cheevx/zheevx returned an error code:
 If $info = i \leq n$, cheevx/zheevx failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array $ifail$;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegvx` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size (n, n) .
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix Z of size (n, n) , where the values n and m are significant.
<i>ifail</i>	Holds the vector of length (n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <i>ifail</i> is present and z is omitted.
<i>range</i>	Restored based on the presence of arguments vl , vu , il , iu as follows: $range = 'V'$, if one of or both vl and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of vl , vu , il , iu is present, Note that there will be an error condition if one of or both vl and vu are present and at the same time one of or both il and iu are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * \text{lamch}('S')$.

For optimum performance use $lwork \geq (nb+1)*n$, where nb is the blocksize for `chetrd/zhetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call sspgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, info)
call dspgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, info)
```

Fortran 95:

```
call spgv(a, b, w [,itype] [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B ;

If *uplo* = 'L', arrays *ap* and *bp* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ap, *bp*, *work* REAL for sspgv
DOUBLE PRECISION for dspgv.

Arrays:
ap(*) contains the packed upper or lower triangle of the symmetric matrix *A*, as specified by *uplo*.
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.
bp(*) contains the packed upper or lower triangle of the symmetric matrix *B*, as specified by *uplo*.
 The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.
work(*) is a workspace array, DIMENSION at least $\max(1, 3n)$.

ldz INTEGER. The leading dimension of the output array *z*; *ldz* ≥ 1 . If *jobz* = 'V', *ldz* $\geq \max(1, n)$.

Output Parameters

ap On exit, the contents of *ap* are overwritten.

bp On exit, contains the triangular factor *U* or *L* from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as *B*.

w, *z* REAL for sspgv
DOUBLE PRECISION for dspgv.

Arrays:
w(*), DIMENSION at least $\max(1, n)$.
 If *info* = 0, contains the eigenvalues in ascending order.
z(*ldz*,*).
 The second dimension of *z* must be at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:
 if *itype* = 1 or 2, $Z^T * B * Z = I$;
 if *itype* = 3, $Z^T * \text{inv}(B) * Z = I$;
 If *jobz* = 'N', then *z* is not referenced.

info INTEGER.

If $info = 0$, the execution is successful.
 If $info = -i$, the i -th argument had an illegal value.
 If $info > 0$, `sppttrf/dppttrf` and `sspev/dspev` returned an error code:
 If $info = i \leq n$, `sspev/dspev` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;
 If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgv` interface are the following:

a	Stands for argument a_p in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
b	Stands for argument b_p in Fortran 77 interface. Holds the array B of size $(n * (n+1) / 2)$.
w	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$itype$	Must be 1, 2, or 3. The default value is 1.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

?hpgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call chpgv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, rwork, info)
call zhpv(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hpgv(a, b, w [,itype] [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of A and B ;

	If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ap</i> , <i>bp</i> , <i>work</i>	COMPLEX for <i>chpgv</i> DOUBLE COMPLEX for <i>zhpgv</i> . Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>bp</i> (*) contains the packed upper or lower triangle of the Hermitian matrix <i>B</i> , as specified by <i>uplo</i> . The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> (*) is a workspace array, DIMENSION at least $\max(1, 2n-1)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>rwork</i>	REAL for <i>chpgv</i> DOUBLE PRECISION for <i>zhpgv</i> . Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H U$ or $B = L^* L^H$, in the same storage format as <i>B</i> .
<i>w</i>	REAL for <i>chpgv</i> DOUBLE PRECISION for <i>zhpgv</i> . Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for <i>chpgv</i> DOUBLE COMPLEX for <i>zhpgv</i> . Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows:

if $itype = 1$ or 2 , $Z^H * B * Z = I$;
 if $itype = 3$, $Z^H * \text{inv}(B) * Z = I$;
 If $jobz = 'N'$, then z is not referenced.
info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th argument had an illegal value.
 If $info > 0$, `cpptrf/zpptrf` and `chpev/zhpev` returned an error code:
 If $info = i \leq n$, `chpev/zhpev` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;
 If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpgv` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>b</i>	Stands for argument <i>bp</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(n * (n+1) / 2)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

?spgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call sspgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, iwork,
liwork, info)

call dspgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, iwork,
liwork, info)
```

Fortran 95:

```
call spgvd(a, b, w [,itype] [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A*x = \lambda*B*x, \quad A*B*x = \lambda*x, \quad \text{or} \quad B*A*x = \lambda*x.$$

Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i>; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ap, bp, work</i>	REAL for sspgvd DOUBLE PRECISION for dspgvd. Arrays: <i>ap</i>(*) contains the packed upper or lower triangle of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>. The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>bp</i>(*) contains the packed upper or lower triangle of the symmetric matrix <i>B</i>, as specified by <i>uplo</i>. The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints: If $n \leq 1$, $lwork \geq 1$; If <i>jobz</i> = 'N' and $n > 1$, $lwork \geq 2n$; If <i>jobz</i> = 'V' and $n > 1$, $lwork \geq 2n^2 + 6n + 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the required sizes of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, its dimension $\max(1, lwork)$.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i>. Constraints:

If $n \leq 1$, $liwork \geq 1$;
 If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
 If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as <i>B</i> .
<i>w, z</i>	REAL for sspgv DOUBLE PRECISION for dspgv. Arrays: $w(*)$, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order. $z(ldz,*)$. The second dimension of <i>z</i> must be at least $\max(1, n)$. If $jobz = 'V'$, then if $info = 0$, <i>z</i> contains the matrix <i>Z</i> of eigenvectors. The eigenvectors are normalized as follows: if $itype = 1$ or 2 , $Z^T * B * Z = I$; if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$; If $jobz = 'N'$, then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, if $info = 0$, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>iwork</i> (1)	On exit, if $info = 0$, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th argument had an illegal value.

If $info > 0$, `sppttrf/dppttrf` and `sspevd/dspevd` returned an error code:

If $info = i \leq n$, `sspevd/dspevd` failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgvd` interface are the following:

a	Stands for argument ap in Fortran 77 interface. Holds the array A of size $(n*(n+1)/2)$.
b	Stands for argument bp in Fortran 77 interface. Holds the array B of size $(n*(n+1)/2)$.
w	Holds the vector of length (n) .
z	Holds the matrix Z of size (n, n) .
$itype$	Must be 1, 2, or 3. The default value is 1.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$jobz$	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run, or set $lwork = -1$ ($liwork = -1$).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hpgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with matrices in packed storage. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)

call zhpgvd(itype, jobz, uplo, n, ap, bp, w, z, ldz, work, lwork, rwork,
lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hpgvd(a, b, w [,itype] [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here *A* and *B* are assumed to be Hermitian, stored in packed format, and *B* is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A*x = \lambda*B*x$; if <i>itype</i> = 2, the problem type is $A*B*x = \lambda*x$; if <i>itype</i> = 3, the problem type is $B*A*x = \lambda*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i>; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ap, bp, work</i>	COMPLEX for <i>chpgvd</i> DOUBLE COMPLEX for <i>zhpgvd</i>. Arrays: <i>ap</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>. The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>bp</i>(*) contains the packed upper or lower triangle of the Hermitian matrix <i>B</i>, as specified by <i>uplo</i>. The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>; <i>ldz</i> ≥ 1. If <i>jobz</i> = 'V', <i>ldz</i> $\geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. Constraints: If $n \leq 1$, <i>lwork</i> ≥ 1; If <i>jobz</i> = 'N' and $n > 1$, <i>lwork</i> $\geq n$; If <i>jobz</i> = 'V' and $n > 1$, <i>lwork</i> $\geq 2n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork

REAL for *chpgvd*

DOUBLE PRECISION for *zhpgvd*.

Workspace array, its dimension $\max(1, lrwork)$.

lrwork

INTEGER.

The dimension of the array *rwork*.

Constraints:

If $n \leq 1$, $lrwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;

If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork

INTEGER.

Workspace array, its dimension $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

Constraints:

If $n \leq 1$, $liwork \geq 1$;

If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as B .
<i>w</i>	REAL for <code>chpgvd</code> DOUBLE PRECISION for <code>zhpgvd</code> . Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for <code>chpgvd</code> DOUBLE COMPLEX for <code>zhpgvd</code> . Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, <i>z</i> contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value. If <i>info</i> > 0, <code>cpptrf/zpptrf</code> and <code>chpevd/zhpevd</code> returned an error code: If <i>info</i> = <i>i</i> ≤ <i>n</i> , <code>chpevd/zhpevd</code> failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpgvd` interface are the following:

<i>a</i>	Stands for argument <i>ap</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Stands for argument <i>bp</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set $lwork = -1$ ($liwork = -1$, $lrwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?spgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call sspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, iwork, ifail, info)

call dspgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call spgvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here *A* and *B* are assumed to be symmetric, stored in packed format, and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved:
 if *itype* = 1, the problem type is $A^*x = \lambda^*B^*x$;
 if *itype* = 2, the problem type is $A^*B^*x = \lambda^*x$;
 if *itype* = 3, the problem type is $B^*A^*x = \lambda^*x$.

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu.$ If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ap</i> and <i>bp</i> store the upper triangles of <i>A</i> and <i>B</i>; If <i>uplo</i> = 'L', arrays <i>ap</i> and <i>bp</i> store the lower triangles of <i>A</i> and <i>B</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ap, bp, work</i>	REAL for sspgvx DOUBLE PRECISION for dspgvx. Arrays: <i>ap</i>(*) contains the packed upper or lower triangle of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>. The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$. <i>bp</i>(*) contains the packed upper or lower triangle of the symmetric matrix <i>B</i>, as specified by <i>uplo</i>. The dimension of <i>bp</i> must be at least $\max(1, n*(n+1)/2)$. <i>work</i>(*) is a workspace array, DIMENSION at least $\max(1, 8n)$.
<i>vl, vu</i>	REAL for sspgvx DOUBLE PRECISION for dspgvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $vl < vu$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.

Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
 If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol REAL for sspgvx
 DOUBLE PRECISION for dspgvx.
 The absolute error tolerance for the eigenvalues. See *Application Notes* for more information.

ldz INTEGER. The leading dimension of the output array z .
 Constraints:
 $ldz \geq 1$; if $jobz = 'V'$, $ldz \geq \max(1, n)$.

iwork INTEGER.
 Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap On exit, the contents of ap are overwritten.

bp On exit, contains the triangular factor U or L from the Cholesky factorization $B = U^T * U$ or $B = L * L^T$, in the same storage format as B .

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu - il + 1$.

w, z REAL for sspgvx
 DOUBLE PRECISION for dspgvx.
 Arrays:
 $w(*)$, DIMENSION at least $\max(1, n)$.
 If $info = 0$, contains the eigenvalues in ascending order.
 $z(ldz, *)$.
 The second dimension of z must be at least $\max(1, n)$.
 If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.
 The eigenvectors are normalized as follows:
 if $itype = 1$ or 2 , $Z^T * B * Z = I$;
 if $itype = 3$, $Z^T * \text{inv}(B) * Z = I$;

If $jobz = 'N'$, then z is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, *spptrf*/*dpptf* and *sspevx*/*dspevx* returned an error code:

If $info = i \leq n$, *sspevx*/*dspevx* failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spgvx* interface are the following:

<i>a</i>	Stands for argument a_p in Fortran 77 interface. Holds the array A of size $(n * (n+1) / 2)$.
<i>b</i>	Stands for argument b_p in Fortran 77 interface. Holds the array B of size $(n * (n+1) / 2)$.

<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector of length (<i>n</i>).
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is <i>vl</i> = -HUGE(<i>vl</i>).
<i>vu</i>	Default value for this element is <i>vu</i> = HUGE(<i>vl</i>).
<i>il</i>	Default value for this argument is <i>il</i> = 1.
<i>iu</i>	Default value for this argument is <i>iu</i> = <i>n</i> .
<i>abstol</i>	Default value for this element is <i>abstol</i> = 0.0_WP.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \|T\|_1$ is used instead, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, set *abstol* to $2 * \text{lamch}('S')$.

?hpgvx

Computes selected eigenvalues and, optionally, eigenvectors of a generalized Hermitian definite eigenproblem with matrices in packed storage.

Syntax

FORTRAN 77:

```
call chpgvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, rwork, iwork, ifail, info)
```

```
call zhpgrvx(itype, jobz, range, uplo, n, ap, bp, vl, vu, il, iu, abstol, m,
w, z, ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hpgvx(a, b, w [,itype] [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$A^*x = \lambda^*B^*x, A^*B^*x = \lambda^*x, \text{ or } B^*A^*x = \lambda^*x.$$

Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>itype</i>	INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: if <i>itype</i> = 1, the problem type is $A^*x = \lambda^*B^*x$; if <i>itype</i> = 2, the problem type is $A^*B^*x = \lambda^*x$; if <i>itype</i> = 3, the problem type is $B^*A^*x = \lambda^*x$.
<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'.

If *range* = 'A', the routine computes all eigenvalues.
 If *range* = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:
 $vl < \lambda(i) \leq vu$.
 If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', arrays *ap* and *bp* store the upper triangles of *A* and *B*;
 If *uplo* = 'L', arrays *ap* and *bp* store the lower triangles of *A* and *B*.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

ap, bp, work COMPLEX for *chpgvx*
 DOUBLE COMPLEX for *zhpgvx*.
Arrays:
ap(*) contains the packed upper or lower triangle of the Hermitian matrix *A*, as specified by *uplo*.
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.
bp(*) contains the packed upper or lower triangle of the Hermitian matrix *B*, as specified by *uplo*.
 The dimension of *bp* must be at least $\max(1, n*(n+1)/2)$.
work(*) is a workspace array, DIMENSION at least $\max(1, 2n)$.

vl, vu REAL for *chpgvx*
 DOUBLE PRECISION for *zhpgvx*.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for *chpgvx*

	DOUBLE PRECISION for zhpqvx. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> ≥ 1 . If <i>jobz</i> = 'V', <i>ldz</i> $\geq \max(1, n)$.
<i>rwork</i>	REAL for chpgvx DOUBLE PRECISION for zhpqvx. Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>ap</i>	On exit, the contents of <i>ap</i> are overwritten.
<i>bp</i>	On exit, contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $B = U^H * U$ or $B = L * L^H$, in the same storage format as <i>B</i> .
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.
<i>w</i>	REAL for chpgvx DOUBLE PRECISION for zhpqvx. Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.
<i>z</i>	COMPLEX for chpgvx DOUBLE COMPLEX for zhpqvx. Array <i>z</i> (<i>ldz</i> ,*). The second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>A</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). The eigenvectors are normalized as follows: if <i>itype</i> = 1 or 2, $Z^H * B * Z = I$; if <i>itype</i> = 3, $Z^H * \text{inv}(B) * Z = I$; If <i>jobz</i> = 'N', then <i>z</i> is not referenced.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of *ifail* are zero; if $info > 0$, the *ifail* contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then *ifail* is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, *cpptrf/zpptrf* and *chpevx/zhpevx* returned an error code:

If $info = i \leq n$, *chpevx/zhpevx* failed to converge, and i eigenvectors failed to converge. Their indices are stored in the array *ifail*;

If $info = n + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hpgvx* interface are the following:

<i>a</i>	Stands for argument <i>a_p</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(n * (n+1) / 2)$.
<i>b</i>	Stands for argument <i>b_p</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(n * (n+1) / 2)$.
<i>w</i>	Holds the vector of length (n) .

<i>z</i>	Holds the matrix <i>z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector of length (n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \cdot \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon \cdot ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 \cdot \text{lamch}('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 \cdot \text{lamch}('S')$.

?sbgv

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call ssbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
call dsbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, info)
```

Fortran 95:

```
call sbgv(a, b, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
<i>ab, bb, work</i>	REAL for ssbgv

DOUBLE PRECISION for dsbgv

Arrays:

$ab(ldab,*)$ is an array containing either upper or lower triangular part of the symmetric matrix A (as specified by $uplo$) in band storage format.

The second dimension of the array ab must be at least $\max(1, n)$.

$bb(lddb,*)$ is an array containing either upper or lower triangular part of the symmetric matrix B (as specified by $uplo$) in band storage format.

The second dimension of the array bb must be at least $\max(1, n)$.

$work(*)$ is a workspace array, dimension at least $\max(1, 3n)$

$ldab$

INTEGER. The first dimension of the array ab ; must be at least $ka+1$.

$ldbb$

INTEGER. The first dimension of the array bb ; must be at least $kb+1$.

ldz

INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.

Output Parameters

ab

On exit, the contents of ab are overwritten.

bb

On exit, contains the factor S from the split Cholesky factorization $B = S^T * S$, as returned by [spbstf/dpbstf](#).

w, z

REAL for ssbgv

DOUBLE PRECISION for dsbgv

Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.

info If *jobz* = 'N', then *z* is not referenced.
 INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th argument had an illegal value.
 If *info* > 0, and
 if $i \leq n$, the algorithm failed to converge, and *i* off-diagonal
 elements of an intermediate tridiagonal did not converge to
 zero;
 if $info = n + i$, for $1 \leq i \leq n$, then [spbstf/dpbstf](#)
 returned *info* = *i* and *B* is not positive-definite. The
 factorization of *B* could not be completed and no eigenvalues
 or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sbgv* interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(ka+1, n)$.
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?hbgv

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call chbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
```

```
call zhbgv(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hbgv(a, b, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are Hermitian and banded matrices, and matrix B is also positive definite.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of A and B ; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of A and B .
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in A ($ka \geq 0$).

<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> (<i>kb</i> ≥ 0).
<i>ab, bb, work</i>	COMPLEX for <i>chbgv</i> DOUBLE COMPLEX for <i>zhbgv</i> Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least <i>ka</i> +1.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least <i>kb</i> +1.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> ≥ 1 . If <i>jobz</i> = 'V', <i>ldz</i> $\geq \max(1, n)$.
<i>rwork</i>	REAL for <i>chbgv</i> DOUBLE PRECISION for <i>zhbgv</i> . Workspace array, DIMENSION at least $\max(1, 3n)$.

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>S</i> from the split Cholesky factorization $B = S^H * S$, as returned by cpbstf/zpbstf .
<i>w</i>	REAL for <i>chbgv</i> DOUBLE PRECISION for <i>zhbgv</i> . Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues in ascending order.

z COMPLEX for chbgv
 DOUBLE COMPLEX for zhbgv
 Array *z*(*ldz*,*).
 The second dimension of *z* must be at least max(1, *n*).
 If *jobz* = 'V', then if *info* = 0, *z* contains the matrix *Z*
 of eigenvectors, with the *i*-th column of *z* holding the
 eigenvector associated with $w(i)$. The eigenvectors are
 normalized so that $Z^H * B * Z = I$.
 If *jobz* = 'N', then *z* is not referenced.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th argument had an illegal value.
 If *info* > 0, and
 if $i \leq n$, the algorithm failed to converge, and *i* off-diagonal
 elements of an intermediate tridiagonal did not converge to
 zero;
 if *info* = *n* + *i*, for $1 \leq i \leq n$, then cpbstf/zpbstf
 returned *info* = *i* and *B* is not positive-definite. The
 factorization of *B* could not be completed and no eigenvalues
 or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine hbgv interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size (<i>ka</i> +1, <i>n</i>).
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size (<i>kb</i> +1, <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present,

`jobz = 'N'`, if `z` is omitted.

?sbgvd

Computes all eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call ssbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
            iwork, liwork, info)

call dsbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
            iwork, liwork, info)
```

Fortran 95:

```
call sbgvd(a, b, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<code>jobz</code>	CHARACTER*1. Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then compute eigenvalues only. If <code>jobz = 'V'</code> , then compute eigenvalues and eigenvectors.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , arrays <code>ab</code> and <code>bb</code> store the upper triangles of A and B ; If <code>uplo = 'L'</code> , arrays <code>ab</code> and <code>bb</code> store the lower triangles of A and B .

<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).
<i>ab, bb, work</i>	REAL for ssbgvd DOUBLE PRECISION for dsbgvd Arrays: <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraints: If $n \leq 1$, $lwork \geq 1$; If <i>jobz</i> = 'N' and $n > 1$, $lwork \geq 3n$; If <i>jobz</i> = 'V' and $n > 1$, $lwork \geq 2n^2+5n+1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> and <i>iwork</i> arrays, returns these values as the first entries of the

work and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.
Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*.
Constraints:
If $n \leq 1$, $liwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;
If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.
If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ab On exit, the contents of *ab* are overwritten.

bb On exit, contains the factor *s* from the split Cholesky factorization $B = S^T * S$, as returned by [spbstf/dpbstf](#).

w, *z* REAL for [ssbgvd](#)
DOUBLE PRECISION for [dsbgvd](#)
Arrays:
w(*), DIMENSION at least $\max(1, n)$.
If *info* = 0, contains the eigenvalues in ascending order.
z(*ldz*,*).
The second dimension of *z* must be at least $\max(1, n)$.
If $jobz = 'V'$, then if *info* = 0, *z* contains the matrix *Z* of eigenvectors, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*). The eigenvectors are normalized so that $Z^T * B * Z = I$.
If $jobz = 'N'$, then *z* is not referenced.

<code>work(1)</code>	On exit, if <code>info = 0</code> , then <code>work(1)</code> returns the required minimal size of <code>lwork</code> .
<code>iwork(1)</code>	On exit, if <code>info = 0</code> , then <code>iwork(1)</code> returns the required minimal size of <code>liwork</code> .
<code>info</code>	INTEGER. If <code>info = 0</code>, the execution is successful. If <code>info = -i</code>, the <i>i</i>-th argument had an illegal value. If <code>info > 0</code>, and if $i \leq n$, the algorithm failed to converge, and <i>i</i> off-diagonal elements of an intermediate tridiagonal did not converge to zero; if <code>info = n + i</code>, for $1 \leq i \leq n$, then <code>spbstf/dpbstf</code> returned <code>info = i</code> and <i>B</i> is not positive-definite. The factorization of <i>B</i> could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgvd` interface are the following:

<code>a</code>	Stands for argument <code>ab</code> in Fortran 77 interface. Holds the array <i>A</i> of size $(ka+1, n)$.
<code>b</code>	Stands for argument <code>bb</code> in Fortran 77 interface. Holds the array <i>B</i> of size $(kb+1, n)$.
<code>w</code>	Holds the vector of length (n) .
<code>z</code>	Holds the matrix <i>Z</i> of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument <i>z</i> as follows: <code>jobz = 'V'</code>, if <i>z</i> is present, <code>jobz = 'N'</code>, if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $work$ ($liwork$) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hbgvd

Computes all eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with banded matrices. If eigenvectors are desired, it uses a divide and conquer method.

Syntax

FORTRAN 77:

```
call chbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
rwork, lrwork, iwork, liwork, info)

call zhbgvd(jobz, uplo, n, ka, kb, ab, ldab, bb, ldbb, w, z, ldz, work, lwork,
rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call hbgvd(a, b, w [,uplo] [,z] [,info])
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = \lambda^*B^*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).
<i>ab, bb, work</i>	COMPLEX for chbgvd DOUBLE COMPLEX for zhbgvd Arrays: <i>ab</i> (<i>ldab</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.

lwork INTEGER.
The dimension of the array *work*.
Constraints:
If $n \leq 1$, $lwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $lwork \geq n$;
If $jobz = 'V'$ and $n > 1$, $lwork \geq 2n^2$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork REAL for *chbgvd*
DOUBLE PRECISION for *zhbgvd*.
Workspace array, DIMENSION $\max(1, lrwork)$.

lrwork INTEGER.
The dimension of the array *rwork*.
Constraints:
If $n \leq 1$, $lrwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $lrwork \geq n$;
If $jobz = 'V'$ and $n > 1$, $lrwork \geq 2n^2 + 5n + 1$.
If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.
Workspace array, DIMENSION $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*.
Constraints:
If $n \leq 1$, $lwork \geq 1$;
If $jobz = 'N'$ and $n > 1$, $liwork \geq 1$;

If $jobz = 'V'$ and $n > 1$, $liwork \geq 5n + 3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

ab	On exit, the contents of ab are overwritten.
bb	On exit, contains the factor s from the split Cholesky factorization $B = S^H * S$, as returned by cpbstf/zpbstf .
w	REAL for chbgvd DOUBLE PRECISION for zhbgvd . Array, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order.
z	COMPLEX for chbgvd DOUBLE COMPLEX for zhbgvd Array $z(ldz, *)$. The second dimension of z must be at least $\max(1, n)$. If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^H * B * Z = I$. If $jobz = 'N'$, then z is not referenced.
$work(1)$	On exit, if $info = 0$, then $work(1)$ returns the required minimal size of $lwork$.
$rwork(1)$	On exit, if $info = 0$, then $rwork(1)$ returns the required minimal size of $lrwork$.
$iwork(1)$	On exit, if $info = 0$, then $iwork(1)$ returns the required minimal size of $liwork$.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th argument had an illegal value. If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then `cpbstf/zpbstf` returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbgvd` interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(ka+1, n)$.
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set $lwork = -1$ ($liwork = -1$, $lrwork = -1$).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call ssbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, iwork, ifail, info)

call dsbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, iwork, ifail, info)
```

Fortran 95:

```
call sbgvx(a, b, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = \lambda B^*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<code>jobz</code>	CHARACTER*1. Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then compute eigenvalues only. If <code>jobz = 'V'</code> , then compute eigenvalues and eigenvectors.
<code>range</code>	CHARACTER*1. Must be 'A' or 'V' or 'I'.

	If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu.$ If <i>range</i> = 'I', the routine computes eigenvalues in range <i>il</i> to <i>iu</i>.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).
<i>ab, bb, work</i>	REAL for <i>ssbgvx</i> DOUBLE PRECISION for <i>dsbgvx</i> Arrays: <i>ab</i> (<i>ldab</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i>,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, DIMENSION (7*n).
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>vl, vu</i>	REAL for <i>ssbgvx</i>

	DOUBLE PRECISION for dsbgvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: <i>vl</i> < <i>vu</i> . If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; <i>il</i> =1 and <i>iu</i> =0 if $n = 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	REAL for ssbgvx DOUBLE PRECISION for dsbgvx. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> ≥ 1. If <i>jobz</i> = 'V', <i>ldz</i> ≥ max(1, <i>n</i>).
<i>ldq</i>	INTEGER. The leading dimension of the output array <i>q</i> ; <i>ldq</i> < 1. If <i>jobz</i> = 'V', <i>ldq</i> < max(1, <i>n</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (5*n).

Output Parameters

<i>ab</i>	On exit, the contents of <i>ab</i> are overwritten.
<i>bb</i>	On exit, contains the factor <i>s</i> from the split Cholesky factorization $B = S^T * S$, as returned by spbstf / dpbstf .
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', <i>m</i> = <i>n</i> , and if <i>range</i> = 'I', <i>m</i> = <i>iu</i> - <i>il</i> +1.
<i>w, z, q</i>	REAL for ssbgvx DOUBLE PRECISION for dsbgvx Arrays: <i>w</i> (*), DIMENSION at least max(1, <i>n</i>) . If <i>info</i> = 0, contains the eigenvalues in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^T * B * Z = I$.

If $jobz = 'N'$, then z is not referenced.

$q(ldq,*)$.

The second dimension of q must be at least $\max(1, n)$.

If $jobz = 'V'$, then q contains the n -by- n matrix used in the reduction of $A * x = \lambda * B * x$ to standard form, that is, $C * x = \lambda * x$ and consequently C to tridiagonal form.

If $jobz = 'N'$, then q is not referenced.

$ifail$

INTEGER.

Array, DIMENSION (m).

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [spbstf/dpbstf](#) returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbgvx` interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(ka+1, n)$.
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>ifail</i>	Holds the vector of length (n) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * ||T||_1$ is used as tolerance, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * ?lamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to 2*?lamch('S').

?hbgvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem with banded matrices.

Syntax

FORTRAN 77:

```
call chbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)

call zhbgvx(jobz, range, uplo, n, ka, kb, ab, ldab, bb, ldbb, q, ldq, vl, vu,
il, iu, abstol, m, w, z, ldz, work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hbgvx(a, b, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,q]
[,abstol] [,info])
```

Description

This routine computes selected eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x = \lambda*B*x$. Here *A* and *B* are assumed to be Hermitian and banded, and *B* is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$.

	If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>ab</i> and <i>bb</i> store the upper triangles of <i>A</i> and <i>B</i>; If <i>uplo</i> = 'L', arrays <i>ab</i> and <i>bb</i> store the lower triangles of <i>A</i> and <i>B</i>.
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($kb \geq 0$).
<i>ab, bb, work</i>	COMPLEX for chbgvx DOUBLE COMPLEX for zhbgvx Arrays: <i>ab</i> (<i>ldab</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>B</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, DIMENSION at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i>; must be at least <i>ka</i>+1.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i>; must be at least <i>kb</i>+1.
<i>vl, vu</i>	REAL for chbgvx DOUBLE PRECISION for zhbgvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.

	Constraint: $vl < vu$. If $range = 'A'$ or $'I'$, vl and vu are not referenced.
il, iu	INTEGER. If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$. If $range = 'A'$ or $'V'$, il and iu are not referenced.
$abstol$	REAL for chbgvx DOUBLE PRECISION for zhbgbvx. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
ldz	INTEGER. The leading dimension of the output array z ; $ldz \geq 1$. If $jobz = 'V'$, $ldz \geq \max(1, n)$.
ldq	INTEGER. The leading dimension of the output array q ; $ldq \geq 1$. If $jobz = 'V'$, $ldq \geq \max(1, n)$.
$rwork$	REAL for chbgvx DOUBLE PRECISION for zhbgbvx. Workspace array, DIMENSION at least $\max(1, 7n)$.
$iwork$	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ab	On exit, the contents of ab are overwritten.
bb	On exit, contains the factor s from the split Cholesky factorization $B = S^H * S$, as returned by cpbstf/zpbstf .
m	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.
w	REAL for chbgvx DOUBLE PRECISION for zhbgbvx. Array $w(*)$, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues in ascending order.
z, q	COMPLEX for chbgvx

DOUBLE COMPLEX for zhbgvx

Arrays:

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, z contains the matrix Z of eigenvectors, with the i -th column of z holding the eigenvector associated with $w(i)$. The eigenvectors are normalized so that $Z^H * B * Z = I$.

If $jobz = 'N'$, then z is not referenced.

$q(ldq,*)$.

The second dimension of q must be at least $\max(1, n)$.

If $jobz = 'V'$, then q contains the n -by- n matrix used in the reduction of $Ax = \lambda Bx$ to standard form, that is, $Cx = \lambda x$ and consequently C to tridiagonal form.

If $jobz = 'N'$, then q is not referenced.

$ifail$

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices of the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th argument had an illegal value.

If $info > 0$, and

if $i \leq n$, the algorithm failed to converge, and i off-diagonal elements of an intermediate tridiagonal did not converge to zero;

if $info = n + i$, for $1 \leq i \leq n$, then [cpbstf/zpbstf](#) returned $info = i$ and B is not positive-definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbgvx` interface are the following:

<i>a</i>	Stands for argument <i>ab</i> in Fortran 77 interface. Holds the array <i>A</i> of size $(ka+1, n)$.
<i>b</i>	Stands for argument <i>bb</i> in Fortran 77 interface. Holds the array <i>B</i> of size $(kb+1, n)$.
<i>w</i>	Holds the vector of length (n) .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>ifail</i>	Holds the vector of length (n) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0\_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted. Note that there will be an error condition if <i>ifail</i> or <i>q</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>vl</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * \text{lamch}('S')$.

Generalized Nonsymmetric Eigenproblems

This section describes LAPACK driver routines used for solving generalized nonsymmetric eigenproblems. See also computational routines [computational routines](#) that can be called to solve these problems. [Table 4-14](#) lists all such driver routines for Fortran 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-14 Driver Routines for Solving Generalized Nonsymmetric Eigenproblems

Routine Name	Operation performed
?gges	Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.
?ggesx	Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.
?ggeev	Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.
?ggevx	Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

?gges

Computes the generalized eigenvalues, Schur form, and the left and/or right Schur vectors for a pair of nonsymmetric matrices.

Syntax

FORTRAN 77:

```
call sgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alphas,
alpha, beta, vsl, ldvsl, vsr, ldvsr, work, lwork, bwork, info)

call dgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alphas,
alpha, beta, vsl, ldvsl, vsr, ldvsr, work, lwork, bwork, info)

call cgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alpha, beta,
vsl, ldvsl, vsr, ldvsr, work, lwork, rwork, bwork, info)

call zgges(jobvsl, jobvsr, sort, selctg, n, a, lda, b, ldb, sdim, alpha, beta,
vsl, ldvsl, vsr, ldvsr, work, lwork, rwork, bwork, info)
```

Fortran 95:

```
call gges(a, b, alphas, alpha, beta [,vsl] [,vsr] [,select] [,sdim] [,info])
call gges(a, b, alpha, beta [, vsl] [,vsr] [,select] [,sdim] [,info])
```

Description

This routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors (vsl and vsr). This gives the generalized Schur factorization

$$(A,B) = (vsl * S * vsr^H, vsl * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T . The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver [?ggeev](#) instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A, B) is a scalar w or a ratio $\alpha / \beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero. A pair of matrices (S, T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S, T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

<i>jobvsl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvsl</i> = 'N', then the left Schur vectors are not computed. If <i>jobvsl</i> = 'V', then the left Schur vectors are computed.
<i>jobvsr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvsr</i> = 'N', then the right Schur vectors are not computed. If <i>jobvsr</i> = 'V', then the right Schur vectors are computed.
<i>sort</i>	CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>selctg</i>).
<i>selctg</i>	LOGICAL FUNCTION of three REAL arguments for real flavors. LOGICAL FUNCTION of two COMPLEX arguments for complex flavors. <i>selctg</i> must be declared EXTERNAL in the calling subroutine.

If *sort* = 'S', *selctg* is used to select eigenvalues to sort to the top left of the Schur form.

If *sort* = 'N', *selctg* is not referenced.

For real flavors:

An eigenvalue $(\text{alphan}(j) + \text{alphai}(j))/\text{betan}(j)$ is selected if *selctg*(*alphan*(*j*), *alphai*(*j*), *betan*(*j*)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy *selctg*(*alphan*(*j*), *alphai*(*j*), *betan*(*j*)) = .TRUE. after ordering. In this case *info* is set to *n*+2 .

For complex flavors:

An eigenvalue $\text{alpha}(j) / \text{beta}(j)$ is selected if *selctg*(*alpha*(*j*), *beta*(*j*)) is true.

Note that a selected complex eigenvalue may no longer satisfy *selctg*(*alpha*(*j*), *beta*(*j*)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case *info* is set to *n*+2 (see *info* below).

n INTEGER. The order of the matrices *A*, *B*, *vsl*, and *vsr* (*n* ≥ 0).

a, *b*, *work* REAL for sgges
DOUBLE PRECISION for dgges
COMPLEX for cgges
DOUBLE COMPLEX for zgges.

Arrays:

a(*lda*,*) is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).

The second dimension of *a* must be at least max(1, *n*).

b(*ldb*,*) is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).

The second dimension of *b* must be at least max(1, *n*).

work is a workspace array, its dimension max(1, *lwork*) .

lda INTEGER. The first dimension of the array *a*. Must be at least max(1, *n*).

<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> . Must be at least $\max(1, n)$.
<i>ldvsl, ldvsr</i>	INTEGER. The first dimensions of the output matrices <i>vsl</i> and <i>vsr</i> , respectively. Constraints: $ldvsl \geq 1$. If <i>jobvsl</i> = 'V', $ldvsl \geq \max(1, n)$. $ldvsr \geq 1$. If <i>jobvsr</i> = 'V', $ldvsr \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork \geq \max(1, 8n+16)$ for real flavors; $lwork \geq \max(1, 2n)$ for complex flavors. For good performance, <i>lwork</i> must generally be larger. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla .
<i>rwork</i>	REAL for <i>cgges</i> DOUBLE PRECISION for <i>zgges</i> Workspace array, DIMENSION at least $\max(1, 8n)$. This array is used in complex flavors only.
<i>bwork</i>	LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$. Not referenced if <i>sort</i> = 'N'.

Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	INTEGER. If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>selctg</i> is true. Note that for real flavors complex conjugate pairs for which <i>selctg</i> is true for either eigenvalue count as 2.
<i>alphar, alpha</i>	REAL for <i>sgges</i> ;

DOUBLE PRECISION for dgges.
 Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.
 See *beta*.

alpha COMPLEX for cgges;
 DOUBLE COMPLEX for zgges.
 Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta REAL for sgges
 DOUBLE PRECISION for dgges
 COMPLEX for cgges
 DOUBLE COMPLEX for zgges.
 Array, DIMENSION at least $\max(1, n)$.
For real flavors:
 On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.
 $\text{alphar}(j) + \text{alphai}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A, B) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{alphai}(j+1)$ negative.
For complex flavors:
 On exit, $\text{alpha}(j)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues. $\text{alpha}(j)$, $j=1, \dots, n$, and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (S, T) output by cgges/zgges. The $\text{beta}(j)$ will be non-negative real.
 See also *Application Notes* below.

vsl, vsr REAL for sgges
 DOUBLE PRECISION for dgges
 COMPLEX for cgges
 DOUBLE COMPLEX for zgges.
 Arrays:
vsl(*ldvsl*,*), the second dimension of *vsl* must be at least $\max(1, n)$.

If `jobvsl = 'V'`, this array will contain the left Schur vectors.

If `jobvsl = 'N'`, `vsl` is not referenced.

`vsr(ldvsr,*)`, the second dimension of `vsr` must be at least $\max(1, n)$.

If `jobvsr = 'V'`, this array will contain the right Schur vectors.

If `jobvsr = 'N'`, `vsr` is not referenced.

`work(1)` On exit, if `info = 0`, then `work(1)` returns the required minimal size of `lwork`.

`info` INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the *i*th parameter had an illegal value.

If `info = i`, and

$i \leq n$:

the *QZ* iteration failed. (*A*, *B*) is not in Schur form, but `alphar(j)`, `alphai(j)` (for real flavors), or `alpha(j)` (for complex flavors), and `beta(j)`, $j = \text{info} + 1, \dots, n$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n + 1$: other than *QZ* iteration failed in [?hgeqz](#);

$i = n + 2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy `selctg = .TRUE..`
This could also be caused due to scaling;

$i = n + 3$: reordering failed in [?tgsen](#).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gges` interface are the following:

<code>a</code>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<code>b</code>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<code>alphar</code>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<code>alphai</code>	Holds the vector of length (<i>n</i>). Used in real flavors only.

<i>alpha</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (<i>n</i> , <i>n</i>).
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (<i>n</i> , <i>n</i>).
<i>jobvsl</i>	Restored based on the presence of the argument <i>vsl</i> as follows: <i>jobvsl</i> = 'V', if <i>vsl</i> is present, <i>jobvsl</i> = 'N', if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows: <i>jobvsr</i> = 'V', if <i>vsr</i> is present, <i>jobvsr</i> = 'N', if <i>vsr</i> is omitted.
<i>sort</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>sort</i> = 'S', if <i>select</i> is present, <i>sort</i> = 'N', if <i>select</i> is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar*(*j*)/*beta*(*j*) and *alphai*(*j*)/*beta*(*j*) may easily over- or underflow, and *beta*(*j*) may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* will be always less than and usually comparable with *norm*(*A*) in magnitude, and *beta* always less than and usually comparable with *norm*(*B*).

sggesx

Computes the generalized eigenvalues, Schur form, and, optionally, the left and/or right matrices of Schur vectors.

Syntax

FORTRAN 77:

```
call sggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
            alphas, alphas, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork,
            iwork, liwork, bwork, info)
```

```
call dggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
            alphas, alphas, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork,
            iwork, liwork, bwork, info)
```

```
call cggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
            alpha, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, rwork,
            iwork, liwork, bwork, info)
```

```
call zggesx (jobvsl, jobvsr, sort, selctg, sense, n, a, lda, b, ldb, sdim,
            alpha, beta, vsl, ldvsl, vsr, ldvsr, rconde, rcondv, work, lwork, rwork,
            iwork, liwork, bwork, info)
```

Fortran 95:

```
call ggesx(a, b, alphas, alphas, beta [,vsl] [,vsr] [,select] [,sdim] [,rconde]
[, rcondv] [,info])
```

```
call ggesx(a, b, alpha, beta [, vsl] [,vsr] [,select] [,sdim] [,rconde]
[, rcondv] [, info])
```

Description

This routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, the generalized real/complex Schur form (S,T) , optionally, the left and/or right matrices of Schur vectors (vsl and vsr). This gives the generalized Schur factorization

$$(A,B) = (vsl * S * vsr^H, vsl * T * vsr^H)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T ; computes a reciprocal condition number for the average of the selected eigenvalues ($rconde$); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues ($rcondv$). The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha / \beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero. A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues. A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal of T are non-negative real numbers.

Input Parameters

jobvsl CHARACTER*1. Must be 'N' or 'V'.
 If *jobvsl* = 'N', then the left Schur vectors are not computed.
 If *jobvsl* = 'V', then the left Schur vectors are computed.

jobvsr CHARACTER*1. Must be 'N' or 'V'.
 If *jobvsr* = 'N', then the right Schur vectors are not computed.
 If *jobvsr* = 'V', then the right Schur vectors are computed.

<i>sort</i>	CHARACTER*1. Must be 'N' or 'S'. Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. If <i>sort</i> = 'N', then eigenvalues are not ordered. If <i>sort</i> = 'S', eigenvalues are ordered (see <i>selctg</i>).
<i>selctg</i>	LOGICAL FUNCTION of three REAL arguments for real flavors. LOGICAL FUNCTION of two COMPLEX arguments for complex flavors. <i>selctg</i> must be declared EXTERNAL in the calling subroutine. If <i>sort</i> = 'S', <i>selctg</i> is used to select eigenvalues to sort to the top left of the Schur form. If <i>sort</i> = 'N', <i>selctg</i> is not referenced. For real flavors: An eigenvalue $(\text{alphan}(j) + \text{alphai}(j))/\text{beta}(j)$ is selected if <i>selctg</i>(<i>alphan</i>(<i>j</i>), <i>alphai</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy <i>selctg</i>(<i>alphan</i>(<i>j</i>), <i>alphai</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) = .TRUE. after ordering. In this case <i>info</i> is set to <i>n</i>+2. For complex flavors: An eigenvalue $\text{alpha}(j) / \text{beta}(j)$ is selected if <i>selctg</i>(<i>alpha</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) is true. Note that a selected complex eigenvalue may no longer satisfy <i>selctg</i>(<i>alpha</i>(<i>j</i>), <i>beta</i>(<i>j</i>)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case <i>info</i> is set to <i>n</i>+2 (see <i>info</i> below).
<i>sense</i>	CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed. If <i>sense</i> = 'N', none are computed; If <i>sense</i> = 'E', computed for average of selected eigenvalues only; If <i>sense</i> = 'V', computed for selected deflating subspaces only; If <i>sense</i> = 'B', computed for both.

If *sense* is 'E', 'V', or 'B', then *sort* must equal 'S'.

n
INTEGER. The order of the matrices *A*, *B*, *vsl*, and *vsr* ($n \geq 0$).

a, *b*, *work*
REAL for sggesx
DOUBLE PRECISION for dggesx
COMPLEX for cggesx
DOUBLE COMPLEX for zggesx.
Arrays:
a(lda,)* is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).
The second dimension of *a* must be at least $\max(1, n)$.
b(ldb,)* is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).
The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda
INTEGER. The first dimension of the array *a*.
Must be at least $\max(1, n)$.

ldb
INTEGER. The first dimension of the array *b*.
Must be at least $\max(1, n)$.

ldvsl, *ldvsr*
INTEGER. The first dimensions of the output matrices *vsl* and *vsr*, respectively. Constraints:
 $ldvsl \geq 1$. If *jobvsl* = 'V', $ldvsl \geq \max(1, n)$.
 $ldvsr \geq 1$. If *jobvsr* = 'V', $ldvsr \geq \max(1, n)$.

lwork
INTEGER.
The dimension of the array *work*.
For real flavors:
If $n=0$ then $lwork \geq 1$.
If $n>0$ and *sense* = 'N', then $lwork \geq \max(8*n, 6*n+16)$.
If $n>0$ and *sense* = 'E', 'V', or 'B', then $lwork \geq \max(8*n, 6*n+16, 2*sdim*(n-sdim))$;
For complex flavors:
If $n=0$ then $lwork \geq 1$.
If $n>0$ and *sense* = 'N', then $lwork \geq \max(1, 2*n)$;

If $n > 0$ and $sense = 'E', 'V', \text{ or } 'B'$, then $lwork \geq \max(1, 2*n, 2*sdim*(n-sdim))$.

Note that $2*sdim*(n-sdim) \leq n*n/2$.

An error is only returned if $lwork < \max(8*n, 6*n+16)$ for real flavors, and $lwork < \max(1, 2*n)$ for complex flavors, but if $sense = 'E', 'V', \text{ or } 'B'$, this may not be large enough.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

rwork

REAL for cggexx

DOUBLE PRECISION for zggesx

Workspace array, DIMENSION at least $\max(1, 8n)$.

This array is used in complex flavors only.

iwork

INTEGER.

Workspace array, DIMENSION $\max(1, liwork)$.

liwork

INTEGER.

The dimension of the array *iwork*.

If $sense = 'N'$, or $n = 0$, then $liwork \geq 1$,

otherwise $liwork \geq (n+6)$ for real flavors, and $liwork \geq (n+2)$ for complex flavors.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the bound on the optimal size of the *work* array and the minimum size of the *iwork* array, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by xerbla.

bwork

LOGICAL.

Workspace array, DIMENSION at least $\max(1, n)$.

Not referenced if $sort = 'N'$.

Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	INTEGER. If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>selctg</i> is true. Note that for real flavors complex conjugate pairs for which <i>selctg</i> is true for either eigenvalue count as 2.
<i>alphar, alphas</i>	REAL for <i>sggesx</i> ; DOUBLE PRECISION for <i>dggesx</i> . Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	COMPLEX for <i>cggesx</i> ; DOUBLE COMPLEX for <i>zggesx</i> . Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	REAL for <i>sggesx</i> DOUBLE PRECISION for <i>dggesx</i> COMPLEX for <i>cggesx</i> DOUBLE COMPLEX for <i>zggesx</i> . Array, DIMENSION at least $\max(1, n)$. <i>For real flavors:</i> On exit, $(\text{alphar}(j) + \text{alphas}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$ will be the generalized eigenvalues. $\text{alphar}(j) + \text{alphas}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (<i>S</i> , <i>T</i>) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (<i>A</i> , <i>B</i>) were further reduced to triangular form using complex unitary transformations. If $\text{alphas}(j)$ is zero, then the <i>j</i> -th eigenvalue is real; if positive, then the <i>j</i> -th and (<i>j</i> +1)-st eigenvalues are a complex conjugate pair, with $\text{alphas}(j+1)$ negative. <i>For complex flavors:</i>

On exit, $\alpha(j)/\beta(j)$, $j=1,\dots, n$ will be the generalized eigenvalues. $\alpha(j)$, $j=1,\dots, n$, and $\beta(j)$, $j=1,\dots, n$ are the diagonals of the complex Schur form (S, T) output by `cggesx/zggesx`. The $\beta(j)$ will be non-negative real. See also *Application Notes* below.

vsl, vsr

REAL for `sggesx`
 DOUBLE PRECISION for `dggesx`
 COMPLEX for `cggesx`
 DOUBLE COMPLEX for `zggesx`.

Arrays:

`vsl(ldvsl,*)`, the second dimension of *vsl* must be at least $\max(1, n)$.

If `jobvsl = 'V'`, this array will contain the left Schur vectors.

If `jobvsl = 'N'`, *vsl* is not referenced.

`vsr(ldvsr,*)`, the second dimension of *vsr* must be at least $\max(1, n)$.

If `jobvsr = 'V'`, this array will contain the right Schur vectors.

If `jobvsr = 'N'`, *vsr* is not referenced.

rconde, rcondv

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION (2) each

If `sense = 'E' or 'B'`, `rconde(1)` and `rconde(2)` contain the reciprocal condition numbers for the average of the selected eigenvalues.

Not referenced if `sense = 'N' or 'V'`.

If `sense = 'V' or 'B'`, `rcondv(1)` and `rcondv(2)` contain the reciprocal condition numbers for the selected deflating subspaces.

Not referenced if `sense = 'N' or 'E'`.

work(1)

On exit, if `info = 0`, then `work(1)` returns the required minimal size of *lwork*.

iwork(1)

On exit, if `info = 0`, then `iwork(1)` returns the required minimal size of *liwork*.

info

INTEGER.

If `info = 0`, the execution is successful.

If $info = -i$, the i th parameter had an illegal value.
 If $info = i$, and
 $i \leq n$:
 the QZ iteration failed. (A, B) is not in Schur form, but $alpha_r(j)$, $alpha_i(j)$ (for real flavors), or $alpha(j)$ (for complex flavors), and $beta(j)$, $j=info+1, \dots, n$ should be correct.
 $i > n$: errors that usually indicate LAPACK problems:
 $i = n+1$: other than QZ iteration failed in `?hgeqz`;
 $i = n+2$: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy `selctg = .TRUE..`
 This could also be caused due to scaling;
 $i = n+3$: reordering failed in `?tgsen`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggesx` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>alphar</i>	Holds the vector of length (n) . Used in real flavors only.
<i>alphai</i>	Holds the vector of length (n) . Used in real flavors only.
<i>alpha</i>	Holds the vector of length (n) . Used in complex flavors only.
<i>beta</i>	Holds the vector of length (n) .
<i>vsl</i>	Holds the matrix <i>VSL</i> of size (n, n) .
<i>vsr</i>	Holds the matrix <i>VSR</i> of size (n, n) .
<i>rconde</i>	Holds the vector of length (2) .
<i>rcondv</i>	Holds the vector of length (2) .
<i>jobvsl</i>	Restored based on the presence of the argument <i>vsl</i> as follows: <code>jobvsl = 'V'</code> , if <i>vsl</i> is present, <code>jobvsl = 'N'</code> , if <i>vsl</i> is omitted.
<i>jobvsr</i>	Restored based on the presence of the argument <i>vsr</i> as follows:

	$jobvsr = 'V',$ if vsr is present, $jobvsr = 'N',$ if vsr is omitted.
$sort$	Restored based on the presence of the argument $select$ as follows: $sort = 'S',$ if $select$ is present, $sort = 'N',$ if $select$ is omitted.
$sense$	Restored based on the presence of arguments $rconde$ and $rcondv$ as follows: $sense = 'B',$ if both $rconde$ and $rcondv$ are present, $sense = 'E',$ if $rconde$ is present and $rcondv$ omitted, $sense = 'V',$ if $rconde$ is omitted and $rcondv$ present, $sense = 'N',$ if both $rconde$ and $rcondv$ are omitted.

Note that there will be an error condition if $rconde$ or $rcondv$ are present and $select$ is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If you choose the first option and set any of admissible $lwork$ (or $liwork$) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work, iwork$) on exit. Use this value ($work(1), iwork(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work, iwork$). This operation is called a workspace query.

Note that if you set $lwork$ ($liwork$) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients $\alpha(j)/\beta(j)$ and $\alpha_{\text{hi}}(j)/\beta(j)$ may easily over- or underflow, and $\beta(j)$ may even be zero. Thus, you should avoid simply computing the ratio. However, α and α_{hi} will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and β always less than and usually comparable with $\text{norm}(B)$.

?ggeev

Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.

Syntax

FORTRAN 77:

```
call sggev(jobvl, jobvr, n, a, lda, b, ldb, alphas, alphas, beta, vl, ldvl,
vr, ldvr, work, lwork, info)

call dggev(jobvl, jobvr, n, a, lda, b, ldb, alphas, alphas, beta, vl, ldvl,
vr, ldvr, work, lwork, info)

call cggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr,
work, lwork, rwork, info)

call zggev(jobvl, jobvr, n, a, lda, b, ldb, alpha, beta, vl, ldvl, vr, ldvr,
work, lwork, rwork, info)
```

Fortran 95:

```
call ggev(a, b, alphas, alphas, beta [,vl] [,vr] [,info])
call ggev(a, b, alpha, beta [, vl] [,vr] [,info])
```

Description

This routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta = 0$ and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^H A = \lambda(j) * u(j)^H B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

<i>jobvl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.
<i>jobvr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>n</i>	INTEGER. The order of the matrices <i>A</i>, <i>B</i>, <i>vl</i>, and <i>vr</i> ($n \geq 0$).
<i>a</i> , <i>b</i> , <i>work</i>	REAL for sggev DOUBLE PRECISION for dggev COMPLEX for cggev DOUBLE COMPLEX for zggev. Arrays: <i>a</i>(<i>lda</i>,*) is an array containing the <i>n</i>-by-<i>n</i> matrix <i>A</i> (first of the pair of matrices). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i>(<i>ldb</i>,*) is an array containing the <i>n</i>-by-<i>n</i> matrix <i>B</i> (second of the pair of matrices). The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i>. Must be at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i>. Must be at least $\max(1, n)$.
<i>ldvl</i> , <i>ldvr</i>	INTEGER. The first dimensions of the output matrices <i>vl</i> and <i>vr</i>, respectively. Constraints:

$ldvl \geq 1$. If $jobvl = 'V'$, $ldvl \geq \max(1, n)$.
 $ldvr \geq 1$. If $jobvr = 'V'$, $ldvr \geq \max(1, n)$.
lwork INTEGER.
 The dimension of the array *work*.
 $lwork \geq \max(1, 8n+16)$ for real flavors;
 $lwork \geq \max(1, 2n)$ for complex flavors.
 For good performance, *lwork* must generally be larger.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
rwork REAL for *cggev*
 DOUBLE PRECISION for *zggev*
 Workspace array, DIMENSION at least $\max(1, 8n)$.
 This array is used in complex flavors only.

Output Parameters

a, b On exit, these arrays have been overwritten.
alphar, alphas REAL for *sggev*;
 DOUBLE PRECISION for *dggev*.
 Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.
 See *beta*.
alpha COMPLEX for *cggev*;
 DOUBLE COMPLEX for *zggev*.
 Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.
beta REAL for *sggev*
 DOUBLE PRECISION for *dggev*
 COMPLEX for *cggev*
 DOUBLE COMPLEX for *zggev*.
 Array, DIMENSION at least $\max(1, n)$.
 For real flavors:
 On exit, $(\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, are the generalized eigenvalues.

vl, vr

If $\alpha_i(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\alpha_i(j+1)$ negative.

For complex flavors:

On exit, $\alpha(j)/\beta(j)$, $j=1, \dots, n$, are the generalized eigenvalues.

See also *Application Notes* below.

REAL for sggev
DOUBLE PRECISION for dggev
COMPLEX for cggev
DOUBLE COMPLEX for zggev.

Arrays:

$vl(ldvl,*)$; the second dimension of vl must be at least $\max(1, n)$.

If $jobvl = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of vl , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvl = 'N'$, vl is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = vl(:, j)$, the j -th column of vl .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = vl(:, j) + i*vl(:, j+1)$ and $u(j+1) = vl(:, j) - i*vl(:, j+1)$, where $i = \text{sqrt}(-1)$.

For complex flavors:

$u(j) = vl(:, j)$, the j -th column of vl .

$vr(ldvr,*)$; the second dimension of vr must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:,j) + i*vr(:,j+1)$ and $v(j+1) = vr(:,j) - i*vr(:,j+1)$.
For complex flavors:
 $v(j) = vr(:,j)$, the j -th column of vr .

work(1) On exit, if *info* = 0, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, and
 i ≤ *n*: the QZ iteration failed. No eigenvectors have been calculated, but *alphar*(*j*), *alphai*(*j*) (for real flavors), or *alpha*(*j*) (for complex flavors), and *beta*(*j*), *j*=*info*+1, ..., *n* should be correct.
 i > *n*: errors that usually indicate LAPACK problems:
 i = *n*+1: other than QZ iteration failed in ?hgeqz;
 i = *n*+2: error return from ?tgevc.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggeev* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alphai</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alpha</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>n</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>n</i>).
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present,

jobvl = 'N', if *vl* is omitted.

jobvr Restored based on the presence of the argument *vr* as follows:

jobvr = 'V', if *vr* is present,

jobvr = 'N', if *vr* is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar*(j)/*beta*(j) and *alphai*(j)/*beta*(j) may easily over- or underflow, and *beta*(j) may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with *norm(A)* in magnitude, and *beta* always less than and usually comparable with *norm(B)*.

?ggev

Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

Syntax

call ggev(a, b, alpha, beta [, vl] [,vr] [,balanc] [,ilo] [,ihi] [,lscale]
[, rscale] [,abnrm] [,bbnrm] [,rconde] [,rcondv] [,info])
```

Description

This routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (*ilo*, *ihi*, *lscale*, *rscale*, *abnrm*, and *bbnrm*), reciprocal condition numbers for the eigenvalues (*rconde*), and reciprocal condition numbers for the right eigenvectors (*rcondv*).

A generalized eigenvalue for a pair of matrices (A, B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$ and even for both being zero. The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A, B) satisfies

$$u(j)^H * A = \lambda(j) * u(j)^H * B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

<i>balanc</i>	CHARACTER*1. Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed. If <i>balanc</i> = 'N', do not diagonally scale or permute; If <i>balanc</i> = 'P', permute only; If <i>balanc</i> = 'S', scale only; If <i>balanc</i> = 'B', both permute and scale. Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.
<i>jobvl</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.
<i>jobvr</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>sense</i>	CHARACTER*1. Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed. If <i>sense</i> = 'N', none are computed;

If *sense* = 'E', computed for eigenvalues only;
 If *sense* = 'V', computed for eigenvectors only;
 If *sense* = 'B', computed for eigenvalues and eigenvectors.

n INTEGER. The order of the matrices *A*, *B*, *vl*, and *vr* ($n \geq 0$).

a, *b*, *work* REAL for sggevx
 DOUBLE PRECISION for dggevx
 COMPLEX for cggevx
 DOUBLE COMPLEX for zggevx.

Arrays:
a(*lda*,*) is an array containing the *n*-by-*n* matrix *A* (first of the pair of matrices).
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) is an array containing the *n*-by-*n* matrix *B* (second of the pair of matrices).
 The second dimension of *b* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of the array *a*.
 Must be at least $\max(1, n)$.

ldb INTEGER. The first dimension of the array *b*.
 Must be at least $\max(1, n)$.

ldvl, *ldvr* INTEGER. The first dimensions of the output matrices *vl* and *vr*, respectively.

Constraints:
 $ldvl \geq 1$. If *jobvl* = 'V', $ldvl \geq \max(1, n)$.
 $ldvr \geq 1$. If *jobvr* = 'V', $ldvr \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*. $lwork \geq \max(1, 2*n)$;
For real flavors:
 If *balanc* = 'S', or 'B', or *jobvl* = 'V', or *jobvr* = 'V', then $lwork \geq \max(1, 6*n)$;
 if *sense* = 'E', or 'B', then $lwork \geq \max(1, 10*n)$;
 if *sense* = 'V', or 'B', $lwork \geq (2n^2 + 8*n + 16)$.
For complex flavors:

if *sense* = 'E', *lwork* $\geq \max(1, 4*n)$;
 if *sense* = 'V', or 'B', *lwork* $\geq \max(1, 2*n^2 + 2*n)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).

rwork REAL for *cggev*x
 DOUBLE PRECISION for *zggev*x
 Workspace array, DIMENSION at least $\max(1, 6*n)$ if *balanc* = 'S', or 'B', and at least $\max(1, 2*n)$ otherwise.
 This array is used in complex flavors only.

iwork INTEGER.
 Workspace array, DIMENSION at least $(n+6)$ for real flavors and at least $(n+2)$ for complex flavors.
 Not referenced if *sense* = 'E'.

bwork LOGICAL. Workspace array, DIMENSION at least $\max(1, n)$.
 Not referenced if *sense* = 'N'.

Output Parameters

a, b On exit, these arrays have been overwritten.
 If *jobvl* = 'V' or *jobvr* = 'V' or both, then *a* contains the first part of the real Schur form of the “balanced” versions of the input *A* and *B*, and *b* contains its second part.

alphas, *alphai* REAL for *sggev*x;
 DOUBLE PRECISION for *dggev*x.
 Arrays, DIMENSION at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors.
 See *beta*.

alpha COMPLEX for *cggev*x;
 DOUBLE COMPLEX for *zggev*x.
 Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See *beta*.

beta REAL for *sggev*x
 DOUBLE PRECISION for *dggev*x
 COMPLEX for *cggev*x

v_l, v_r

DOUBLE COMPLEX for zggevz.

Array, DIMENSION at least $\max(1, n)$.

For real flavors:

On exit, $(\alpha(j) + \beta(j)i)/\gamma(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

If $\beta(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\beta(j+1)$ negative.

For complex flavors:

On exit, $\alpha(j)/\gamma(j)$, $j=1, \dots, n$, will be the generalized eigenvalues.

See also *Application Notes* below.

REAL for sggevz

DOUBLE PRECISION for dggevz

COMPLEX for cggevz

DOUBLE COMPLEX for zggevz.

Arrays:

$v_l(ldv_l, *)$; the second dimension of v_l must be at least $\max(1, n)$.

If $jobv_l = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of v_l , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobv_l = 'N'$, v_l is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $u(j) = v_l(:, j)$, the j -th column of v_l .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = v_l(:, j) + i*v_l(:, j+1)$ and $u(j+1) = v_l(:, j) - i*v_l(:, j+1)$, where $i = \text{sqrt}(-1)$.

For complex flavors:

$u(j) = v_l(:, j)$, the j -th column of v_l .

$v_r(ldv_r, *)$; the second dimension of v_r must be at least $\max(1, n)$.

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $abs(Re) + abs(Im) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then $v(j) = vr(:, j)$, the j -th column of vr .

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = vr(:, j) + i*vr(:, j+1)$ and $v(j+1) = vr(:, j) - i*vr(:, j+1)$.

For complex flavors:

$v(j) = vr(:, j)$, the j -th column of vr .

ilo, ihi

INTEGER. *ilo* and *ihi* are integer values such that on exit $A(i, j) = 0$ and $B(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

lscale, rscale

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays, DIMENSION at least $\max(1, n)$ each.

lscale contains details of the permutations and scaling factors applied to the left side of A and B .

If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then

$lscale(j) = PL(j)$, for $j = 1, \dots, ilo-1$
 $= DL(j)$, for $j = ilo, \dots, ihi$
 $= PL(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

rscale contains details of the permutations and scaling factors applied to the right side of A and B .

If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then

$rscale(j) = PR(j)$, for $j = 1, \dots, ilo-1$
 $= DR(j)$, for $j = ilo, \dots, ihi$
 $= PR(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

abnrm, bbnrm REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.
The one-norms of the balanced matrices A and B , respectively.

rconde, rcondv REAL for single precision flavors DOUBLE PRECISION for double precision flavors.
Arrays, DIMENSION at least $\max(1, n)$ each.
If $sense = 'E'$, or $'B'$, *rconde* contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of *rconde* are set to the same value. Thus *rconde*(j), *rcondv*(j), and the j -th columns of v_l and v_r all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected).
If $sense = 'N'$, or $'V'$, *rconde* is not referenced.
If $sense = 'V'$, or $'B'$, *rcondv* contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of *rcondv* are set to the same value.
If the eigenvalues cannot be reordered to compute *rcondv*(j), *rcondv*(j) is set to 0; this can only occur when the true value would be very small anyway.
If $sense = 'N'$, or $'E'$, *rcondv* is not referenced.

work(1) On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

info INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, and
 $i \leq n$:

the *QZ* iteration failed. No eigenvectors have been calculated, but *alphar*(*j*), *alphai*(*j*) (for real flavors), or *alpha*(*j*) (for complex flavors), and *beta*(*j*), *j*=*info*+1, ..., *n* should be correct.

i > *n*: errors that usually indicate LAPACK problems:

i = *n*+1: other than *QZ* iteration failed in ?*hgeqz*;

i = *n*+2: error return from ?*tgevc*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggevx* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>alphar</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alphai</i>	Holds the vector of length (<i>n</i>). Used in real flavors only.
<i>alpha</i>	Holds the vector of length (<i>n</i>). Used in complex flavors only.
<i>beta</i>	Holds the vector of length (<i>n</i>).
<i>vl</i>	Holds the matrix <i>VL</i> of size (<i>n</i> , <i>n</i>).
<i>vr</i>	Holds the matrix <i>VR</i> of size (<i>n</i> , <i>n</i>).
<i>lscale</i>	Holds the vector of length (<i>n</i>).
<i>rscale</i>	Holds the vector of length (<i>n</i>).
<i>rconde</i>	Holds the vector of length (<i>n</i>).
<i>rcondv</i>	Holds the vector of length (<i>n</i>).
<i>balanc</i>	Must be 'N', 'B', or 'P'. The default value is 'N'.
<i>jobvl</i>	Restored based on the presence of the argument <i>vl</i> as follows: <i>jobvl</i> = 'V', if <i>vl</i> is present, <i>jobvl</i> = 'N', if <i>vl</i> is omitted.
<i>jobvr</i>	Restored based on the presence of the argument <i>vr</i> as follows: <i>jobvr</i> = 'V', if <i>vr</i> is present, <i>jobvr</i> = 'N', if <i>vr</i> is omitted.

sense Restored based on the presence of arguments *rconde* and *rcondv* as follows:

sense = 'B', if both *rconde* and *rcondv* are present,
sense = 'E', if *rconde* is present and *rcondv* omitted,
sense = 'V', if *rconde* is omitted and *rcondv* present,
sense = 'N', if both *rconde* and *rcondv* are omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The quotients *alphar*(j)/*beta*(j) and *alphai*(j)/*beta*(j) may easily over- or underflow, and *beta*(j) may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with *norm*(A) in magnitude, and *beta* always less than and usually comparable with *norm*(B).

LAPACK Auxiliary and Utility Routines

5

This chapter describes the Intel® Math Kernel Library implementation of LAPACK [auxiliary](#) and [utility routines](#). The library includes auxiliary routines for both real and complex data.

Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

The table below summarizes information about the available LAPACK auxiliary routines.

Table 5-1 LAPACK Auxiliary Routines

Routine Name	Data Types	Description
?lacgv	c, z	Conjugates a complex vector.
?lacrm	c, z	Multiplies a complex matrix by a square real matrix.
?lacrt	c, z	Performs a linear transformation of a pair of complex vectors.
?laesy	c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix.
?rot	c, z	Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.
?spmv	c, z	Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix
?spr	c, z	Performs the symmetrical rank-1 update of a complex symmetric packed matrix.
?symv	c, z	Computes a matrix-vector product for a complex symmetric matrix.
?syr	c, z	Performs the symmetric rank-1 update of a complex symmetric matrix.
i?max1	c, z	Finds the index of the vector element whose real part has maximum absolute value.

Routine Name	Data Types	Description
?sum1	s, d, dz	Forms the 1-norm of the complex vector using the true absolute value.
?gbtf2	s, d, c, z	Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.
?gebd2	s, d, c, z	Reduces a general matrix to bidiagonal form using an unblocked algorithm.
?gehd2	s, d, c, z	Reduces a general square matrix to upper Hessenberg form using an unblocked algorithm.
?gelq2	s, d, c, z	Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.
?geql2	s, d, c, z	Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.
?geqr2	s, d, c, z	Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.
?gerq2	s, d, c, z	Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.
?gesc2	s, d, c, z	Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2 .
?getc2	s, d, c, z	Computes the LU factorization with complete pivoting of the general n-by-n matrix.
?getf2	s, d, c, z	Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).
?gtts2	s, d, c, z	Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf .
?isnan	s, d,	Tests input for NaN.
?laisnan	s, d,	Tests input for NaN by comparing it two arguments for inequality.

Routine Name	Data Types	Description
?labrd	s, d, c, z	Reduces the first nb rows and columns of a general matrix to a bidiagonal form.
?laln2	s, d, c, z	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.
?lacpy	s, d, c, z	Copies all or part of one two-dimensional array to another.
?ladiv	s, d, c, z	Performs complex division in real arithmetic, avoiding unnecessary overflow.
?lae2	s, d	Computes the eigenvalues of a 2-by-2 symmetric matrix.
?laebz	s, d	Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz .
?laed0	s, d, c, z	Used by ?stedc . Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.
?laed1	s, d	Used by sstedc / dstedc . Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.
?laed2	s, d	Used by sstedc / dstedc . Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.
?laed3	s, d	Used by sstedc / dstedc . Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.
?laed4	s, d	Used by sstedc / dstedc . Finds a single root of the secular equation.
?laed5	s, d	Used by sstedc / dstedc . Solves the 2-by-2 secular equation.

Routine Name	Data Types	Description
?laed6	s, d	Used by <code>sstedc/dstedc</code> . Computes one Newton step in solution of the secular equation.
?laed7	s, d, c, z	Used by <code>?stedc</code> . Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.
?laed8	s, d, c, z	Used by <code>?stedc</code> . Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.
?laed9	s, d	Used by <code>sstedc/dstedc</code> . Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.
?laeda	s, d	Used by <code>?stedc</code> . Computes the z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.
?laein	s, d, c, z	Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.
?laev2	s, d, c, z	Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.
?laexc	s, d	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
?lag2	s, d	Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.
?lags2	s, d	Computes 2-by-2 orthogonal matrices U , V , and Q , and applies them to matrices A and B such that the rows of the transformed A and B are parallel.
?lagtf	s, d	Computes an LU factorization of a matrix $T-\lambda I$, where T is a general tridiagonal matrix, and λ a scalar, using partial pivoting with row interchanges.

Routine Name	Data Types	Description
?lagtm	s, d, c, z	Performs a matrix-matrix product of the form $C = \alpha ab + \beta C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.
?lagts	s, d	Solves the system of equations $(T - \lambda I)x = y$ or $(T - \lambda I)^T x = y$, where T is a general tridiagonal matrix and λ a scalar, using the LU factorization computed by ?lagtf .
?lagv2	s, d	Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A, B) where B is upper triangular.
?lahqr	s, d, c, z	Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.
?lahrd	s, d, c, z	Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?lahr2	s, d, c, z	Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .
?laic1	s, d, c, z	Applies one step of incremental condition estimation.
?laln2	s, d	Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.
?lals0	s, d, c, z	Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd .
?lalsa	s, d, c, z	Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd .
?lalsd	s, d, c, z	Uses the singular value decomposition of A to solve the least squares problem.

Routine Name	Data Types	Description
?lamrg	s, d	Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.
?laneg	s, d	Computes the Sturm count.
?langb	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.
?lange	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.
?langt	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.
?lanhs	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.
?lansb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.
?lanhb	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.
?lansp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.
?lanhp	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.
?lanst/?lanht	s, d/c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.

Routine Name	Data Types	Description
?lansy	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.
?lanhe	c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.
?lantb	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.
?lantp	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.
?lantr	s, d, c, z	Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.
?lanv2	s, d	Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.
?lap11	s, d, c, z	Measures the linear dependence of two vectors.
?lapmt	s, d, c, z	Performs a forward or backward permutation of the columns of a matrix.
?lapy2	s, d	Returns $\sqrt{x^2+y^2}$.
?lapy3	s, d	Returns $\sqrt{x^2+y^2+z^2}$.
?laqgb	s, d, c, z	Scales a general band matrix, using row and column scaling factors computed by ?gbequ .
?laqge	s, d, c, z	Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ .
?laqhb	c, z	Scales a Hermetian band matrix, using scaling factors computed by ?pbequ .

Routine Name	Data Types	Description
?laqp2	s, d, c, z	Computes a QR factorization with column pivoting of the matrix block.
?laqps	s, d, c, z	Computes a step of QR factorization with column pivoting of a real m-by-n matrix <i>A</i> by using BLAS level 3.
?laqr0	s, d, c, z	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr1	s, d, c, z	Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix <i>H</i> and specified shifts.
?laqr2	s, d, c, z	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr3	s, d, c, z	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
?laqr4	s, d, c, z	Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.
?laqr5	s, d, c, z	Performs a single small-bulge multi-shift QR sweep.
?laqsb	s, d, c, z	Scales a symmetric/Hermitian band matrix, using scaling factors computed by ?pbequ .
?laqsp	s, d, c, z	Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ .
?laqsy	s, d, c, z	Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ .
?laqtr	s, d	Solves a real quasi-triangular system of equations, or a complex quasi-triangular system of special form, in real arithmetic.

Routine Name	Data Types	Description
?lar1v	s, d, c, z	Computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $1dL^T - \sigma I$.
?lar2v	s, d, c, z	Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.
?larf	s, d, c, z	Applies an elementary reflector to a general rectangular matrix.
?larfb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
?larfg	s, d, c, z	Generates an elementary reflector (Householder matrix).
?larft	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - vtv^H$.
?larfx	s, d, c, z	Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order ≤ 10 .
?largv	s, d, c, z	Generates a vector of plane rotations with real cosines and real/complex sines.
?larnv	s, d, c, z	Returns a vector of random numbers from a uniform or normal distribution.
?larra	s, d	Computes the splitting points with the specified threshold.
?larrb	s, d	Provides limited bisection to locate eigenvalues for more accuracy.
?larrc	s, d	Computes the number of eigenvalues of the symmetric tridiagonal matrix.
?larrd	s, d	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.
?larre	s, d	Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.

Routine Name	Data Types	Description
?larrf	s, d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrj	s, d	Performs refinement of the initial estimates of the eigenvalues of the matrix T .
?larrk	s, d	Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.
?larrrr	s, d	Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.
?larrv	s, d, c, z	Computes the eigenvectors of the tridiagonal matrix $T = L D L^T$ given L , D and the eigenvalues of $L D L^T$.
?lartg	s, d, c, z	Generates a plane rotation with real cosine and real/complex sine.
?lartv	s, d, c, z	Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.
?laruv	s, d	Returns a vector of n random real numbers from a uniform distribution.
?larz	s, d, c, z	Applies an elementary reflector (as returned by ?tzzrf) to a general matrix.
?larzb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general matrix.
?larzt	s, d, c, z	Forms the triangular factor T of a block reflector $H = I - vtv^H$.
?las2	s, d	Computes singular values of a 2-by-2 triangular matrix.
?lascl	s, d, c, z	Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .
?lasd0	s, d	Computes the singular values of a real upper bidiagonal n-by-m matrix B with diagonal d and off-diagonal e . Used by ?bdsdc .

Routine Name	Data Types	Description
?lasd1	s, d	Computes the SVD of an upper bidiagonal matrix B of the specified size. Used by ?bdsdc .
?lasd2	s, d	Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc .
?lasd3	s, d	Finds all square roots of the roots of the secular equation, as defined by the values in D and Z , and then updates the singular vectors by matrix multiplication. Used by ?bdsdc .
?lasd4	s, d	Computes the square root of the i -th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc .
?lasd5	s, d	Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc .
?lasd6	s, d	Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc .
?lasd7	s, d	Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc .
?lasd8	s, d	Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc .
?lasd9	s, d	Finds the square roots of the roots of the secular equation, and stores, for each element in D , the distance to its two nearest poles. Used by ?bdsdc .
?lasda	s, d	Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc .
?lasdq	s, d	Computes the SVD of a real bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc .

Routine Name	Data Types	Description
<code>?lasdt</code>	<code>s, d</code>	Creates a tree of subproblems for bidiagonal divide and conquer. Used by <code>?bdsdc</code> .
<code>?laset</code>	<code>s, d, c, z</code>	Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.
<code>?lasq1</code>	<code>s, d</code>	Computes the singular values of a real square bidiagonal matrix. Used by <code>?bdsqr</code> .
<code>?lasq2</code>	<code>s, d</code>	Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the <code>qd</code> Array <code>z</code> to high relative accuracy. Used by <code>?bdsqr</code> and <code>?stegr</code> .
<code>?lasq3</code>	<code>s, d</code>	Checks for deflation, computes a shift and calls <code>dqds</code> . Used by <code>?bdsqr</code> .
<code>?lasq4</code>	<code>s, d</code>	Computes an approximation to the smallest eigenvalue using values of <code>d</code> from the previous transform. Used by <code>?bdsqr</code> .
<code>?lasq5</code>	<code>s, d</code>	Computes one <code>dqds</code> transform in ping-pong form. Used by <code>?bdsqr</code> and <code>?stegr</code> .
<code>?lasq6</code>	<code>s, d</code>	Computes one <code>dqd</code> transform in ping-pong form. Used by <code>?bdsqr</code> and <code>?stegr</code> .
<code>?lasr</code>	<code>s, d, c, z</code>	Applies a sequence of plane rotations to a general rectangular matrix.
<code>?lasrt</code>	<code>s, d</code>	Sorts numbers in increasing or decreasing order.
<code>?lassq</code>	<code>s, d, c, z</code>	Updates a sum of squares represented in scaled form.
<code>?lasv2</code>	<code>s, d</code>	Computes the singular value decomposition of a 2-by-2 triangular matrix.
<code>?laswp</code>	<code>s, d, c, z</code>	Performs a series of row interchanges on a general rectangular matrix.
<code>?lasy2</code>	<code>s, d</code>	Solves the Sylvester matrix equation where the matrices are of order 1 or 2.

Routine Name	Data Types	Description
?lasyf	s, d, c, z	Computes a partial factorization of a real/complex symmetric matrix, using the diagonal pivoting method.
?lahef	c, z	Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.
?latbs	s, d, c, z	Solves a triangular banded system of equations.
?latdf	s, d, c, z	Uses the LU factorization of the n-by-n matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.
?latps	s, d, c, z	Solves a triangular system of equations with the matrix held in packed storage.
?latrd	s, d, c, z	Reduces the first <i>nb</i> rows and columns of a symmetric/Hermitian matrix <i>A</i> to real tridiagonal form by an orthogonal/unitary similarity transformation.
?latrs	s, d, c, z	Solves a triangular system of equations with the scale factor set to prevent overflow.
?latrz	s, d, c, z	Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.
?lauu2	s, d, c, z	Computes the product UU^H or L^HL , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (unblocked algorithm).
?lauum	s, d, c, z	Computes the product UU^H or L^HL , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (blocked algorithm).
?lazq3	s, d,	Checks for deflation, computes a shift and calls <i>dqds</i>
?lazq4	s, d,	Computes an approximation to the smallest eigenvalue using values of d from the previous transform.
?org2l/?ung2l	s, d/c, z	Generates all or part of the orthogonal/unitary matrix <i>Q</i> from a QL factorization determined by ?geqlf (unblocked algorithm).

Routine Name	Data Types	Description
?org2r/?ung2r	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by ?geqrf (unblocked algorithm).
?orgl2/?ungl2	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by ?gelqf (unblocked algorithm).
?org2r/?ungr2	s, d/c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by ?gerqf (unblocked algorithm).
?orm2l/?unm2l	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).
?orm2r/?unm2r	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).
?orml2/?unml2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).
?ormr2/?unmr2	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RQ factorization determined by ?gerqf (unblocked algorithm).
?ormr3/?unmr3	s, d/c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzzrf (unblocked algorithm).
?pbt2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite band matrix (unblocked algorithm).
?pot2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (unblocked algorithm).
?ptts2	s, d, c, z	Solves a tridiagonal system of the form $AX=B$ using the $L D L^H$ factorization computed by ?pttrf .

Routine Name	Data Types	Description
?rscl	s, d, cs, zd	Multiplies a vector by the reciprocal of a real scalar.
?sygs2/?hegs2	s, d/c, z	Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).
?sytd2/?hetd2	s, d/c, z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (unblocked algorithm).
?sytf2	s, d, c, z	Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).
?hetf2	c, z	Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).
?tgex2	s, d, c, z	Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.
?tgsy2	s, d, c, z	Solves the generalized Sylvester equation (unblocked algorithm).
?trti2	s, d, c, z	Computes the inverse of a triangular matrix (unblocked algorithm).
clag2z	c $\rightarrow$ z	Converts a complex single precision matrix to a complex double precision matrix.
dlag2s	d $\rightarrow$ s	Converts a double precision matrix to a single precision matrix.
slag2d	s $\rightarrow$ d	Converts a single precision matrix to a double precision matrix.
zlag2c	z $\rightarrow$ c	Converts a complex double precision matrix to a complex single precision matrix.

?lacgv

Conjugates a complex vector.

Syntax

```
call clacgv( n, x, incx )
```

```
call zlacgv( n, x, incx )
```

Description

This routine conjugates a complex vector x of length n and increment $incx$ (see “[Vector Arguments in BLAS](#)” in Appendix B).

Input Parameters

n	INTEGER. The length of the vector x ($n \geq 0$).
x	COMPLEX for clacgv COMPLEX*16 for zlacgv. Array, dimension $(1+(n-1) * incx)$. Contains the vector of length n to be conjugated.
$incx$	INTEGER. The spacing between successive elements of x .

Output Parameters

x	On exit, overwritten with <code>conjg(x)</code> .

?lacrm

Multiplies a complex matrix by a square real matrix.

Syntax

```
call clacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

```
call zlacrm( m, n, a, lda, b, ldb, c, ldc, rwork )
```

Description

This routine performs a simple matrix-matrix multiplication of the form

$$C = A*B,$$

where A is m -by- n and complex, B is n -by- n and real, C is m -by- n and complex.

Input Parameters

m	INTEGER. The number of rows of the matrix A and of the matrix C ($m \geq 0$).
n	INTEGER. The number of columns and rows of the matrix B and the number of columns of the matrix C ($n \geq 0$).
a	COMPLEX for <code>clacrm</code> COMPLEX*16 for <code>zlacrm</code> Array, DIMENSION (lda, n). Contains the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a , $lda \geq \max(1, m)$.
b	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Array, DIMENSION (ldb, n). Contains the n -by- n matrix B .
ldb	INTEGER. The leading dimension of the array b , $ldb \geq \max(1, n)$.
ldc	INTEGER. The leading dimension of the output array c , $ldc \geq \max(1, n)$.
$rwork$	REAL for <code>clacrm</code> DOUBLE PRECISION for <code>zlacrm</code> Workspace array, DIMENSION ($2*m*n$).

Output Parameters

c	COMPLEX for <code>clacrm</code> COMPLEX*16 for <code>zlacrm</code> Array, DIMENSION (ldc, n). Contains the m -by- n matrix C .

zlacrt

Performs a linear transformation of a pair of complex vectors.

Syntax

```
call clacrt( n, cx, incx, cy, incy, c, s )
```

```
call zlacrt( n, cx, incx, cy, incy, c, s )
```

Description

This routine performs the following transformation

$$\begin{pmatrix} c & s \\ -s & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \Rightarrow \begin{pmatrix} x \\ y \end{pmatrix},$$

where c, s are complex scalars and x, y are complex vectors.

Input Parameters

n	INTEGER. The number of elements in the vectors cx and cy ($n \geq 0$).
cx, cy	COMPLEX for clacrt COMPLEX*16 for zlacrt Arrays, dimension (n). Contain input vectors x and y , respectively.
$incx$	INTEGER. The increment between successive elements of cx .
$incy$	INTEGER. The increment between successive elements of cy .
c, s	COMPLEX for clacrt COMPLEX*16 for zlacrt Complex scalars that define the transform matrix

$$\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$$

Output Parameters

<i>cx</i>	On exit, overwritten with $c*x + s*y$.
<i>cy</i>	On exit, overwritten with $-s*x + c*y$.

?laesy

Computes the eigenvalues and eigenvectors of a 2-by-2 complex symmetric matrix, and checks that the norm of the matrix of eigenvectors is larger than a threshold value.

Syntax

```
call claesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
call zlaesy( a, b, c, rt1, rt2, evscal, cs1, sn1 )
```

Description

This routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix},$$

provided the norm of the matrix of eigenvectors is larger than some threshold value.

rt1 is the eigenvalue of larger absolute value, and *rt2* of smaller absolute value. If the eigenvectors are computed, then on return (*cs1*, *sn1*) is the unit eigenvector for *rt1*, hence

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -sn1 \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

Input Parameters

a, b, c COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 Elements of the input matrix.

Output Parameters

rt1, rt2 COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 Eigenvalues of larger and smaller modulus, respectively.

evscal COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 The complex value by which the eigenvector matrix was scaled to make it orthonormal. If *evscal* is zero, the eigenvectors were not computed. This means one of two things: the 2-by-2 matrix could not be diagonalized, or the norm of the matrix of eigenvectors before scaling was larger than the threshold value `thresh` (set to 0.1E0).

cs1, sn1 COMPLEX for `claesy`
 COMPLEX*16 for `zlaesy`
 If *evscal* is not zero, then (*cs1, sn1*) is the unit right eigenvector for *rt1*.

?rot

Applies a plane rotation with real cosine and complex sine to a pair of complex vectors.

Syntax

```
call crot( n, cx, incx, cy, incy, c, s )
call zrot( n, cx, incx, cy, incy, c, s )
```

Description

This routine applies a plane rotation, where the cosine (c) is real and the sine (s) is complex, and the vectors cx and cy are complex. This routine has its real equivalents in BLAS (see [?rot](#) in Chapter 2).

Input Parameters

n	INTEGER. The number of elements in the vectors cx and cy .
cx, cy	COMPLEX for <code>crot</code> COMPLEX*16 for <code>zrot</code> Arrays of dimension (n), contain input vectors x and y , respectively.
$incx$	INTEGER. The increment between successive elements of cx .
$incy$	INTEGER. The increment between successive elements of cy .
c	REAL for <code>crot</code> DOUBLE PRECISION for <code>zrot</code>
s	COMPLEX for <code>crot</code> COMPLEX*16 for <code>zrot</code> Values that define a rotation

$$\begin{bmatrix} c & s \\ -\text{conjg}(s) & c \end{bmatrix}$$

where $c*c + s*\text{conjg}(s) = 1.0$.

Output Parameters

cx	On exit, overwritten with $c*x + s*y$.
cy	On exit, overwritten with $-\text{conjg}(s)*x + c*y$.

?spmv

Computes a matrix-vector product for complex vectors using a complex symmetric packed matrix.

Syntax

```
call cspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
call zspmv( uplo, n, alpha, ap, x, incx, beta, y, incy )
```

Description

These routines perform a matrix-vector operation defined as

$$y := \alpha * a * x + \beta * y,$$

where:

alpha and *beta* are complex scalars,

x and *y* are *n*-element complex vectors

a is an *n*-by-*n* complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see [?spmv](#) in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>a</i> is supplied in the packed array <i>ap</i>. If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>. If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i>. The value of <i>n</i> must be at least zero.
<i>alpha, beta</i>	COMPLEX for cspmv COMPLEX*16 for zspmv Specify complex scalars <i>alpha</i> and <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>ap</i>	COMPLEX for cspmv

	COMPLEX*16 for <code>zspmv</code> Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry, with <code>uplo = 'U'</code> or <code>'u'</code>, the array <code>ap</code> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <code>ap(1)</code> contains $A(1, 1)$, <code>ap(2)</code> and <code>ap(3)</code> contain $A(1, 2)$ and $A(2, 2)$ respectively, and so on. Before entry, with <code>uplo = 'L'</code> or <code>'l'</code>, the array <code>ap</code> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <code>ap(1)</code> contains $a(1, 1)$, <code>ap(2)</code> and <code>ap(3)</code> contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.
<code>x</code>	COMPLEX for <code>cspmv</code> COMPLEX*16 for <code>zspmv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <code>x</code> must contain the n-element vector <code>x</code>.
<code>incx</code>	INTEGER. Specifies the increment for the elements of <code>x</code>. The value of <code>incx</code> must not be zero.
<code>y</code>	COMPLEX for <code>cspmv</code> COMPLEX*16 for <code>zspmv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <code>y</code> must contain the n-element vector <code>y</code>.
<code>incy</code>	INTEGER. Specifies the increment for the elements of <code>y</code>. The value of <code>incy</code> must not be zero.

Output Parameters

<code>y</code>	Overwritten by the updated vector <code>y</code> .

?spr

Performs the symmetrical rank-1 update of a complex symmetric packed matrix.

Syntax

```
call cspr( uplo, n, alpha, x, incx, ap )
```

```
call zspr( uplo, n, alpha, x, incx, ap )
```

Description

The ?spr routines perform a matrix-vector operation defined as

$$a := \alpha * x * \text{conjg}(x') + a,$$

where:

alpha is a complex scalar

x is an *n*-element complex vector

a is an *n*-by-*n* complex symmetric matrix, supplied in packed form.

These routines have their real equivalents in BLAS (see ?spr in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>a</i> is supplied in the packed array <i>ap</i>, as follows: If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>. If <i>uplo</i> = 'L' or 'l', the lower triangular part of the matrix <i>a</i> is supplied in the array <i>ap</i>.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i>. The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for cspr COMPLEX*16 for zspr Specifies the scalar <i>alpha</i>.
<i>x</i>	COMPLEX for cspr COMPLEX*16 for zspr

Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n -element vector x .

incx INTEGER. Specifies the increment for the elements of x . The value of *incx* must not be zero.

ap COMPLEX for *cspr*
COMPLEX*16 for *zspr*
Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry, with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that *ap*(1) contains $A(1, 1)$, *ap*(2) and *ap*(3) contain $A(1, 2)$ and $A(2, 2)$ respectively, and so on.
Before entry, with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1, 1)$, *ap*(2) and *ap*(3) contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on.
Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.

?symv

Computes a matrix-vector product for a complex symmetric matrix.

Syntax

```
call csymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
call zsymv( uplo, n, alpha, a, lda, x, incx, beta, y, incy )
```

Description

These routines perform the matrix-vector operation defined as

$$y := \alpha * a * x + \beta * y,$$

where:

α and β are complex scalars

x and y are n -element complex vectors

a is an n -by- n symmetric complex matrix.

These routines have their real equivalents in BLAS (see [?symv](#) in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i>. The value of <i>n</i> must be at least zero.
<i>alpha, beta</i>	COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Specify the scalars <i>alpha</i> and <i>beta</i>. When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>a</i>	COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading n-by-n upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n-by-n lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.

<i>lda</i>	INTEGER. Specifies the first dimension of <i>A</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <i>csymv</i> COMPLEX*16 for <i>zsymv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

?syr

Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

```
call csyr( uplo, n, alpha, x, incx, a, lda )
call zsyr( uplo, n, alpha, x, incx, a, lda )
```

Description

These routines perform the symmetric rank 1 operation defined as

$$a := \alpha x x^* + a,$$

where:

alpha is a complex scalar

x is an n -element complex vector

a is an n -by- n complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter 2).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array a is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array a is used. If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array a is used.
<i>n</i>	INTEGER. Specifies the order of the matrix a. The value of n must be at least zero.
<i>alpha</i>	COMPLEX for csyr COMPLEX*16 for zsyrr Specifies the scalar <i>alpha</i>.
<i>x</i>	COMPLEX for csyr COMPLEX*16 for zsyrr Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n-element vector x.
<i>incx</i>	INTEGER. Specifies the increment for the elements of x. The value of <i>incx</i> must not be zero.
<i>a</i>	COMPLEX for csyr COMPLEX*16 for zsyrr Array, DIMENSION (<i>lda</i>, n). Before entry with <i>uplo</i> = 'U' or 'u', the leading n-by-n upper triangular part of the array a must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n-by-n lower triangular part of the array a must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of a is not referenced.

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, n)$.

Output Parameters

a With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.
With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.

i?max1

Finds the index of the vector element whose real part has maximum absolute value.

Syntax

```
index = icmax1( n, cx, incx )
```

```
index = izmax1( n, cx, incx )
```

Description

Given a complex vector *cx*, the i?max1 functions return the index of the vector element whose real part has maximum absolute value. These functions are based on the BLAS functions icamax/izamax, but using the absolute value of the real part. They are designed for use with clacon/zlacon.

Input Parameters

n INTEGER. Specifies the number of elements in the vector *cx*.

cx COMPLEX for icmax1
COMPLEX*16 for izmax1
Array, DIMENSION at least $(1 + (n-1) * \text{abs}(incx))$.
Contains the input vector.

incx INTEGER. Specifies the spacing between successive elements of *cx*.

Output Parameters

<i>index</i>	INTEGER. Contains the index of the vector element whose real part has maximum absolute value.

?sum1

Forms the 1-norm of the complex vector using the true absolute value.

Syntax

```
res = scsum1( n, cx, incx )
res = dzsum1( n, cx, incx )
```

Description

Given a complex vector *cx*, *scsum1*/*dzsum1* functions take the sum of the absolute values of vector elements and return a single/DOUBLE PRECISION result, respectively. These functions are based on *scasum*/*dzasum* from Level 1 BLAS, but use the true absolute value and were designed for use with *clacon*/*zlacon*.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in the vector <i>cx</i> .
<i>cx</i>	COMPLEX for <i>scsum1</i> COMPLEX*16 for <i>dzsum1</i> Array, DIMENSION at least $(1+(n-1)*abs(incx))$. Contains the input vector whose elements will be summed.
<i>incx</i>	INTEGER. Specifies the spacing between successive elements of <i>cx</i> (<i>incx</i> > 0).

Output Parameters

<i>res</i>	REAL for <i>scsum1</i> DOUBLE PRECISION for <i>dzsum1</i> Contains the sum of absolute values.

?gbtf2

Computes the LU factorization of a general band matrix using the unblocked version of the algorithm.

Syntax

```
call sgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbtf2( m, n, kl, ku, ab, ldab, ipiv, info )
```

Description

The routine forms the *LU* factorization of a general real/complex *m*-by-*n* band matrix *A* with *kl* sub-diagonals and *ku* super-diagonals. The routine uses partial pivoting with row interchanges and implements the unblocked version of the algorithm, calling Level 2 BLAS. See also [?gbtrf](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab</i>	REAL for sgbtf2 DOUBLE PRECISION for dgbtf2 COMPLEX for cgbtf2 COMPLEX*16 for zgbtf2. Array, DIMENSION (<i>ldab</i> ,*). The array <i>ab</i> contains the matrix <i>A</i> in band storage (see Matrix Arguments). The second dimension of <i>ab</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> .

$$(ldab \geq 2kl + ku + 1)$$

Output Parameters

<i>ab</i>	Overwritten by details of the factorization. The diagonal and $kl + ku$ super-diagonals of U are stored in the first $1 + kl + ku$ rows of <i>ab</i> . The multipliers used during the factorization are stored in the next kl rows.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices: row i was interchanged with row $ipiv(i)$.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

?gebd2

Reduces a general matrix to bidiagonal form using an unblocked algorithm.

Syntax

```
call sgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call dgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call cgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
call zgebd2( m, n, a, lda, d, e, tauq, taup, work, info )
```

Description

The routine reduces a general m -by- n matrix A to upper or lower bidiagonal form B by an orthogonal (unitary) transformation: $Q'^*A^*P = B$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. if $m \geq n$,

$Q = H(1) * H(2) * \dots * H(n)$, and $P = G(1) * G(2) * \dots * G(n-1)$

if $m < n$,

$Q = H(1) * H(2) * \dots * H(m-1)$, and $P = G(1) * G(2) * \dots * G(m)$

Each $H(i)$ and $G(i)$ has the form

$H(i) = I - \text{tauq} * v * v'$ and $G(i) = I - \text{taup} * u * u'$

where tauq and taup are scalars (real for sgebd2/dgebd2, complex for cgebd2/zgebd2), and v and u are vectors (real for sgebd2/dgebd2, complex for cgebd2/zgebd2).

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgebd2
DOUBLE PRECISION for dgebd2
COMPLEX for cgebd2
COMPLEX*16 for zgebd2.
Arrays:
 $a(\text{lda}, *)$ contains the m -by- n general matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.
 $\text{work}(*)$ is a workspace array, the dimension of work must be at least $\max(1, m, n)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a if $m \geq n$, the diagonal and first super-diagonal of a are overwritten with the upper bidiagonal matrix B . Elements below the diagonal, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the first superdiagonal, with the array taup , represent the orthogonal/unitary matrix P as a product of elementary reflectors.
if $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . Elements below the first subdiagonal, with the array tauq , represent

the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements above the diagonal, with the array τ_{aup} , represent the orthogonal/unitary matrix P as a product of elementary reflectors.

d	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the diagonal elements of the bidiagonal matrix B: $d(i) = a(i, i)$.
e	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of the bidiagonal matrix B: if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$.
τ_{auq}, τ_{aup}	REAL for sgebd2 DOUBLE PRECISION for dgebd2 COMPLEX for cgebd2 COMPLEX*16 for zgebd2. Arrays, DIMENSION at least $\max(1, \min(m, n))$. Contain scalar factors of the elementary reflectors which represent orthogonal/unitary matrices Q and P, respectively.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the ith parameter had an illegal value.

?gehd2

*Reduces a general square matrix to upper
Hessenberg form using an unblocked algorithm.*

Syntax

```
call sgehd2( n, ilo, ihi, a, lda, tau, work, info )
call dgehd2( n, ilo, ihi, a, lda, tau, work, info )
call cgehd2( n, ilo, ihi, a, lda, tau, work, info )
call zgehd2( n, ilo, ihi, a, lda, tau, work, info )
```

Description

The routine reduces a real/complex general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $Q^* A Q = H$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*.

Input Parameters

n	INTEGER The order of the matrix A ($n \geq 0$).
ilo, ihi	INTEGER. It is assumed that A is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$. If A has been output by ?gebal, then ilo and ihi must contain the values returned by that routine. Otherwise they should be set to $ilo = 1$ and $ihi = n$. Constraint: $1 \leq ilo \leq ihi \leq \max(1, n)$.
$a, work$	REAL for sgehd2 DOUBLE PRECISION for dgehd2 COMPLEX for cgehd2 COMPLEX*16 for zgehd2. Arrays: $a(lda, *)$ contains the n -by- n matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$. $work(n)$ is a workspace array.
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the upper triangle and the first subdiagonal of <i>A</i> are overwritten with the upper Hessenberg matrix <i>H</i> and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. See <i>Application Notes</i> below.
<i>tau</i>	REAL for sgehd2 DOUBLE PRECISION for dgehd2 COMPLEX for cgehd2 COMPLEX*16 for zgehd2. Array, DIMENSION at least $\max(1, n-1)$. Contains the scalar factors of elementary reflectors. See <i>Application Notes</i> below.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Application Notes

The matrix *Q* is represented as a product of (*ihi* - *ilo*) elementary reflectors

$$Q = H(ilo) * H(ilo + 1) * \dots * H(ihi - 1)$$

Each *H*(*i*) has the form

$$H(i) = I - tau * v * v'$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with *v*(1:*i*) = 0, *v*(*i*+1) = 1 and *v*(*ihi*+1:*n*) = 0.

On exit, *v*(*i*+2:*ihi*) is stored in *a*(*i*+2:*ihi*, *i*) and *tau* in *tau*(*i*).

The contents of *a* are illustrated by the following example, with *n* = 7, *ilo* = 2 and *ihi* = 6:

$$\begin{array}{cc}
 \text{on entry} & \text{on exit} \\
 \left[\begin{array}{cccccc} a & a & a & a & a & a \\ & a & a & a & a & a \\ & & a & a & a & a \\ & & & a & a & a \\ & & & & a & a \\ & & & & & a \end{array} \right] & \left[\begin{array}{cccccc} a & a & h & h & h & h \\ & a & h & h & h & h \\ & & h & h & h & h \\ & & & v_2 & h & h \\ & & & v_2 & v_3 & h \\ & & & v_2 & v_3 & v_4 \end{array} \right] \\
 & \left[\begin{array}{cccccc} & & & & & a \end{array} \right]
 \end{array}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?gelq2

Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgelq2( m, n, a, lda, tau, work, info )
call dgelq2( m, n, a, lda, tau, work, info )
call cgelq2( m, n, a, lda, tau, work, info )
call zgelq2( m, n, a, lda, tau, work, info )
```

Description

The routine computes an LQ factorization of a real/complex m -by- n matrix A as $A = L^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$Q = H(k) \dots H(2) H(1)$ (or $Q = H(k)' \dots H(2)' H(1)'$ for complex flavors), where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:n)$ is stored in $a(i, i+1:n)$.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgelq2</code> DOUBLE PRECISION for <code>dgelq2</code> COMPLEX for <code>cgelq2</code> COMPLEX*16 for <code>zgelq2</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $work(m)$ is a workspace array.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a	Overwritten by the factorization data as follows: on exit, the elements on and below the diagonal of the array a contain the m -by- $\min(n, m)$ lower trapezoidal matrix L (L is lower triangular if $n \geq m$); the elements above the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors.
τ	REAL for <code>sgelq2</code> DOUBLE PRECISION for <code>dgelq2</code> COMPLEX for <code>cgelq2</code> COMPLEX*16 for <code>zgelq2</code> . Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

?geql2

Computes the QL factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeql2( m, n, a, lda, tau, work, info )
call dgeql2( m, n, a, lda, tau, work, info )
call cgeql2( m, n, a, lda, tau, work, info )
call zgeql2( m, n, a, lda, tau, work, info )
```

Description

The routine computes a QL factorization of a real/complex m -by- n matrix A as $A = Q^*L$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(k)^* \dots ^*H(2)^*H(1)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v^*$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$.

On exit, $v(1:m-k+i-1)$ is stored in $a(1:m-k+i-1, n-k+i)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for sgeql2
DOUBLE PRECISION for dgeql2
COMPLEX for cgeql2
COMPLEX*16 for zgeql2.

Arrays:

$a(lda, *)$ contains the m -by- n matrix A .

The second dimension of a must be at least $\max(1, n)$.

work(*m*) is a workspace array.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
on exit, if $m \geq n$, the lower triangle of the subarray
 $a(m-n+1:m, 1:n)$ contains the n -by- n lower triangular
matrix L ; if $m < n$, the elements on and below the $(n-m)$ th
superdiagonal contain the m -by- n lower trapezoidal matrix
 L ; the remaining elements, with the array *tau*, represent
the orthogonal/unitary matrix Q as a product of elementary
reflectors.

tau REAL for sgeql2
DOUBLE PRECISION for dgeql2
COMPLEX for cgeql2
COMPLEX*16 for zgeql2.
Array, DIMENSION at least $\max(1, \min(m, n))$.
Contains scalar factors of the elementary reflectors.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

?geqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgeqr2( m, n, a, lda, tau, work, info )
call dgeqr2( m, n, a, lda, tau, work, info )
call cgeqr2( m, n, a, lda, tau, work, info )
call zgeqr2( m, n, a, lda, tau, work, info )
```

Description

The routine computes a QR factorization of a real/complex m -by- n matrix A as $A = Q * R$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$$Q = H(1) * H(2) * \dots * H(k), \text{ where } k = \min(m, n)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$.

On exit, $v(i+1:m)$ is stored in $a(i+1:m, i)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

$a, work$ REAL for sgeqr2
DOUBLE PRECISION for dgeqr2
COMPLEX for cgeqr2
COMPLEX*16 for zgeqr2.
Arrays:
 $a(lda, *)$ contains the m -by- n matrix A .
The second dimension of a must be at least $\max(1, n)$.
 $work(n)$ is a workspace array.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
on exit, the elements on and above the diagonal of the array
 a contain the $\min(n, m)$ -by- n upper trapezoidal matrix R (R
is upper triangular if $m \geq n$); the elements below the
diagonal, with the array τ , represent the
orthogonal/unitary matrix Q as a product of elementary
reflectors.

τ REAL for sgeqr2
DOUBLE PRECISION for dgeqr2
COMPLEX for cgeqr2

COMPLEX*16 for zgeqr2.
 Array, DIMENSION at least $\max(1, \min(m, n))$.
 Contains scalar factors of the elementary reflectors.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?gerq2

Computes the RQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
call sgerq2( m, n, a, lda, tau, work, info )
call dgerq2( m, n, a, lda, tau, work, info )
call cgerq2( m, n, a, lda, tau, work, info )
call zgerq2( m, n, a, lda, tau, work, info )
```

Description

The routine computes a RQ factorization of a real/complex m -by- n matrix A as $A = R^*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(1) * H(2) * \dots * H(k)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$.

On exit, $v(1:n-k+i-1)$ is stored in $a(m-k+i, 1:n-k+i-1)$.

Input Parameters

m INTEGER. The number of rows in the matrix A ($m \geq 0$).

n INTEGER. The number of columns in A ($n \geq 0$).

a, work REAL for sgerq2
 DOUBLE PRECISION for dgerq2
 COMPLEX for cgerq2
 COMPLEX*16 for zgerq2.
Arrays:
a(lda,)* contains the m -by- n matrix A .
 The second dimension of a must be at least $\max(1, n)$.
work(m) is a workspace array.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

a Overwritten by the factorization data as follows:
 on exit, if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the m -by- m upper triangular matrix R ;
 if $m > n$, the elements on and above the $(m-n)$ -th
 subdiagonal contain the m -by- n upper trapezoidal matrix R ;
 the remaining elements, with the array *tau*, represent the
 orthogonal/unitary matrix Q as a product of elementary
 reflectors.

tau REAL for sgerq2
 DOUBLE PRECISION for dgerq2
 COMPLEX for cgerq2
 COMPLEX*16 for zgerq2.
Array, DIMENSION at least $\max(1, \min(m, n))$.
 Contains scalar factors of the elementary reflectors.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = $-i$, the i -th parameter had an illegal value.

?gesc2

Solves a system of linear equations using the LU factorization with complete pivoting computed by ?getc2.

Syntax

```
call sgesc2( n, a, lda, rhs, ipiv, jpiv, scale )
call dgesec2( n, a, lda, rhs, ipiv, jpiv, scale )
call cgesec2( n, a, lda, rhs, ipiv, jpiv, scale )
call zgesec2( n, a, lda, rhs, ipiv, jpiv, scale )
```

Description

This routine solves a system of linear equations

$$A * X = scale * RHS$$

with a general n -by- n matrix A using the LU factorization with complete pivoting computed by [?getc2](#).

Input Parameters

n	INTEGER. The order of the matrix A .
a, rhs	REAL for <code>sgesc2</code> DOUBLE PRECISION for <code>dgesec2</code> COMPLEX for <code>cgesec2</code> COMPLEX*16 for <code>zgesec2</code> . Arrays: $a(lda, *)$ contains the LU part of the factorization of the n -by- n matrix A computed by <code>?getc2</code> : $A = P * L * U * Q$. The second dimension of a must be at least $\max(1, n)$; $rhs(n)$ contains on entry the right hand side vector for the system of equations.
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, n)$.

jpiv The pivot indices: for $1 \leq i \leq n$, row i of the matrix has been interchanged with row $ipiv(i)$.
 INTEGER.
 Array, DIMENSION at least $\max(1, n)$.
 The pivot indices: for $1 \leq j \leq n$, column j of the matrix has been interchanged with column $jpiv(j)$.

Output Parameters

rhs On exit, overwritten with the solution vector x .
scale REAL for sgesc2/cgesc2
 DOUBLE PRECISION for dgesc2/zgesc2
 Contains the scale factor. *scale* is chosen in the range $0 \leq scale \leq 1$ to prevent overflow in the solution.

?getc2

Computes the LU factorization with complete pivoting of the general n -by- n matrix.

Syntax

```
call sgetc2( n, a, lda, ipiv, jpiv, info )
call dgetc2( n, a, lda, ipiv, jpiv, info )
call cgetc2( n, a, lda, ipiv, jpiv, info )
call zgetc2( n, a, lda, ipiv, jpiv, info )
```

Description

This routine computes an LU factorization with complete pivoting of the n -by- n matrix A . The factorization has the form $A = P^*L^*U^*Q$, where P and Q are permutation matrices, L is lower triangular with unit diagonal elements and U is upper triangular.

The LU factorization computed by this routine is used by [?latdf](#) to compute a contribution to the reciprocal Dif-estimate.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	REAL for sgetc2 DOUBLE PRECISION for dgetc2 COMPLEX for cgetc2 COMPLEX*16 for zgetc2. Array <i>a</i> (<i>lda</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix <i>A</i> to be factored. The second dimension of <i>a</i> must be at least $\max(1, n)$;
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the factors <i>L</i> and <i>U</i> from the factorization $A = P^*L^*U^*Q$; the unit diagonal elements of <i>L</i> are not stored. If <i>U</i> (<i>k</i> , <i>k</i>) appears to be less than <i>smin</i> , <i>U</i> (<i>k</i> , <i>k</i>) is given the value of <i>smin</i> , that is giving a nonsingular perturbed system.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq i \leq n$, row <i>i</i> of the matrix has been interchanged with row <i>ipiv</i> (<i>i</i>).
<i>jpiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: for $1 \leq j \leq n$, column <i>j</i> of the matrix has been interchanged with column <i>jpiv</i> (<i>j</i>).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>k</i> > 0, <i>U</i> (<i>k</i> , <i>k</i>) is likely to produce overflow if we try to solve for <i>x</i> in $A*x = b$. So <i>U</i> is perturbed to avoid the overflow.

?getf2

Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).

Syntax

```
call sgetf2( m, n, a, lda, ipiv, info )
call dgetf2( m, n, a, lda, ipiv, info )
call cgetf2( m, n, a, lda, ipiv, info )
call zgetf2( m, n, a, lda, ipiv, info )
```

Description

The routine computes the LU factorization of a general m -by- n matrix A using partial pivoting with row interchanges. The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
a	REAL for sgetf2 DOUBLE PRECISION for dgetf2 COMPLEX for cgetf2 COMPLEX*16 for zgetf2. Array, DIMENSION ($lda, *$). Contains the matrix A to be factored. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.

Output Parameters

<i>a</i>	Overwritten by <i>L</i> and <i>U</i> . The unit diagonal elements of <i>L</i> are not stored.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices: for $1 \leq i \leq n$, row <i>i</i> was interchanged with row <i>ipiv</i> (<i>i</i>).
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> > 0, <i>u</i> _{<i>ii</i>} is 0. The factorization has been completed, but <i>U</i> is exactly singular. Division by 0 will occur if you use the factor <i>U</i> for solving a system of linear equations.

?gtts2

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf.

Syntax

```
call sgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call dgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call cgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
call zgtts2( itrans, n, nrhs, dl, d, du, du2, ipiv, b, ldb )
```

Description

This routine solves for *x* one of the following systems of linear equations with multiple right hand sides:

$A * X = B$, $A^T * X = B$, or $A^H * X = B$ (for complex matrices only), with a tridiagonal matrix *A* using the *LU* factorization computed by [?gttrf](#).

Input Parameters

<i>itrans</i>	INTEGER. Must be 0, 1, or 2.

	Indicates the form of the equations to be solved: If $itrans = 0$, then $A * X = B$ (no transpose). If $itrans = 1$, then $A^T * X = B$ (transpose). If $itrans = 2$, then $A^H * X = B$ (conjugate transpose).
n	INTEGER. The order of the matrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right-hand sides, i.e., the number of columns in B ($nrhs \geq 0$).
$dl, d, du, du2, b$	REAL for <code>sgtts2</code> DOUBLE PRECISION for <code>dgtts2</code> COMPLEX for <code>cgtts2</code> COMPLEX*16 for <code>zgtts2</code> . Arrays: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $du2(n - 2)$, $b(ldb, nrhs)$. The array dl contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A . The array d contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A . The array du contains the $(n - 1)$ elements of the first super-diagonal of U . The array $du2$ contains the $(n - 2)$ elements of the second super-diagonal of U . The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.
ldb	INTEGER. The leading dimension of b ; must be $ldb \geq \max(1, n)$.
$ipiv$	INTEGER. Array, DIMENSION (n) . The pivot indices array, as returned by <code>?gttrf</code> .

Output Parameters

b	Overwritten by the solution matrix X .

?isnan

Tests input for NaN.

Syntax

```
val = sisnan( sin )
```

```
val = disnan( din )
```

Description

This logical routine returns `.TRUE.` if its argument is NaN, and `.FALSE.` otherwise.

Input Parameters

<i>sin</i>	REAL for <code>sisnan</code> Input to test for NaN.
<i>din</i>	DOUBLE PRECISION for <code>disnan</code> Input to test for NaN.

Output Parameters

<i>val</i>	Logical. Result of the test.

?laisnan

Tests input for NaN.

Syntax

```
val = slaisnan( sin1, sin2 )
```

```
val = dlaisnan( din1, din2 )
```

Description

This logical routine checks for NaNs (NaN stands for 'Not A Number') by comparing its two arguments for inequality. NaN is the only floating-point value where `NaN ≠ NaN` returns `.TRUE.` To check for NaNs, pass the same variable as both arguments.

This routine is not for general use. It exists solely to avoid over-optimization in `?isnan`.

Input Parameters

sin1, sin2 REAL for *sisnan*
Two numbers to compare for inequality.

din2, din2 DOUBLE PRECISION for *disnan*
Two numbers to compare for inequality.

Output Parameters

val Logical. Result of the comparison.

?labrd

Reduces the first nb rows and columns of a general matrix to a bidiagonal form.

Syntax

```
call slabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call dlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call clabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
call zlabrd( m, n, nb, a, lda, d, e, tauq, taup, x, ldx, y, ldy )
```

Description

The routine reduces the first nb rows and columns of a general m -by- n matrix A to upper or lower bidiagonal form by an orthogonal/unitary transformation Q'^*A^*P , and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A .

if $m \geq n$, A is reduced to upper bidiagonal form; if $m < n$, to lower bidiagonal form.

The matrices Q and P are represented as products of elementary reflectors: $Q = H(1) * (2) * \dots * H(nb)$, and $P = G(1) * G(2) * \dots * G(nb)$

Each $H(i)$ and $G(i)$ has the form

$$H(i) = I - \tau v v' \text{ and } G(i) = I - \tau u u'$$

where τ and τ are scalars, and v and u are vectors.

The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are needed, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $A := A - V*Y' - X*U'$.

This is an auxiliary routine called by `?gebrd`.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
nb	INTEGER. The number of leading rows and columns of A to be reduced.
a	REAL for <code>slabrd</code> DOUBLE PRECISION for <code>dlabrd</code> COMPLEX for <code>clabrd</code> COMPLEX*16 for <code>zlabrd</code> . Array $a(lda,*)$ contains the matrix A to be reduced. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
ldx	INTEGER. The first dimension of the output array x ; must beat least $\max(1, m)$.
ldy	INTEGER. The first dimension of the output array y ; must beat least $\max(1, n)$.

Output Parameters

a	On exit, the first nb rows and columns of the matrix are overwritten; the rest of the array is unchanged. if $m \geq n$, elements on and below the diagonal in the first nb columns, with the array τ_{auq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array τ_{aup} , represent the orthogonal/unitary matrix P as a product of elementary reflectors. if $m < n$, elements below the diagonal in the first nb columns, with the array τ_{auq} , represent the orthogonal/unitary matrix Q as a product of elementary

reflectors, and elements on and above the diagonal in the first nb rows, with the array *taup*, represent the orthogonal/unitary matrix p as a product of elementary reflectors.

d, *e* REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors. Arrays, DIMENSION (nb) each. The array *d* contains the diagonal elements of the first nb rows and columns of the reduced matrix:
 $d(i) = a(i, i)$.
 The array *e* contains the off-diagonal elements of the first nb rows and columns of the reduced matrix.

tauq, *taup* REAL for slabrd
 DOUBLE PRECISION for dlabrd
 COMPLEX for clabrd
 COMPLEX*16 for zlabrd.
 Arrays, DIMENSION (nb) each. Contain scalar factors of the elementary reflectors which represent the orthogonal/unitary matrices Q and P , respectively.

x, *y* REAL for slabrd
 DOUBLE PRECISION for dlabrd
 COMPLEX for clabrd
 COMPLEX*16 for zlabrd.
 Arrays, dimension $x(ldx, nb)$, $y(ldy, nb)$.
 The array *x* contains the m -by- nb matrix X required to update the unreduced part of A .
 The array *y* contains the n -by- nb matrix Y required to update the unreduced part of A .

Application Notes

if $m \geq n$, then for the elementary reflectors $H(i)$ and $G(i)$,

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in $a(i:m, i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $a(i, i+1:n)$;

tauq is stored in *tauq*(*i*) and *taup* in *taup*(*i*).

if $m < n$,

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in $a(i+2:m, i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $a(i, i+1:n)$; τ_{auq} is stored in $\tau_{auq}(i)$ and τ_{aup} in $\tau_{aup}(i)$.

The contents of a on exit are illustrated by the following examples with $nb = 2$:

$m=6, n=5$ ($m>n$)

$$\begin{bmatrix} 1 & 1 & u_1 & u_1 & u_1 \\ v_1 & 1 & 1 & u_2 & u_2 \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

$m=5, n=6$ ($m<n$)

$$\begin{bmatrix} 1 & u_1 & u_1 & u_1 & u_1 & u_1 \\ 1 & 1 & u_2 & u_2 & u_2 & u_2 \\ v_1 & 1 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \\ v_1 & v_2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

?lacn2

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacn2( n, v, x, isgn, est, kase, isave )
call dlacn2( n, v, x, isgn, est, kase, isave )
call clacn2( n, v, x, est, kase, isave )
call zlacn2( n, v, x, est, kase, isave )
```

Description

This routine estimates the 1-norm of a square, real or complex matrix A . Reverse communication is used for evaluating matrix-vector products.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 1$).
v, x	REAL for <code>slacn2</code> DOUBLE PRECISION for <code>dlacn2</code> COMPLEX for <code>clacn2</code> COMPLEX*16 for <code>zlacn2</code> . Arrays, DIMENSION (n) each. v is a workspace array. x is used as input after an intermediate return.
$isgn$	INTEGER. Workspace array, DIMENSION (n), used with real flavors only.
est	REAL for <code>slacn2/clacn2</code> DOUBLE PRECISION for <code>dlacn2/zlacn2</code> On entry with $kase$ set to 1 or 2, and $isave(1) = 1$, est must be unchanged from the previous call to the routine.
$kase$	INTEGER. On the initial call to the routine, $kase$ must be set to 0.
$isave$	INTEGER. Array, DIMENSION (3). Contains variables from the previous call to the routine.

Output Parameters

est	An estimate (a lower bound) for $\text{norm}(A)$.
$kase$	On an intermediate return, $kase$ is set to 1 or 2, indicating whether x is overwritten by $A*x$ or $A'*x$. On the final return, $kase$ is set to 0.
v	On the final return, $v = A*w$, where $est = \text{norm}(v) / \text{norm}(w)$ (w is not returned).
x	On an intermediate return, x is overwritten by $A*x$, if $kase = 1$, $A'*x$, if $kase = 2$,

isave (A' is the conjugate transpose of A), and the routine must be re-called with all the other parameters unchanged.

This parameter is used to save variables between calls to the routine.

slacon

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

```
call slacon( n, v, x, isgn, est, kase )
call dlacon( n, v, x, isgn, est, kase )
call clacon( n, v, x, est, kase )
call zlacon( n, v, x, est, kase )
```

Description

This routine estimates the 1-norm of a square, real/complex matrix A. Reverse communication is used for evaluating matrix-vector products.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 1$).
<i>v, x</i>	REAL for slacon DOUBLE PRECISION for dlacon COMPLEX for clacon COMPLEX*16 for zlacon. Arrays, DIMENSION (<i>n</i>) each. <i>v</i> is a workspace array. <i>x</i> is used as input after an intermediate return.
<i>isgn</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>), used with real flavors only.
<i>est</i>	REAL for slacon/clacon DOUBLE PRECISION for dlacon/zlacon

An estimate that with $kase=1$ or 2 should be unchanged from the previous call to `?lacon`.

kase INTEGER.
On the initial call to `?lacon`, *kase* should be 0 .

Output Parameters

est REAL for `slacon/clacon`
DOUBLE PRECISION for `dlacon/zlacon`
An estimate (a lower bound) for $\text{norm}(A)$.

kase On an intermediate return, *kase* will be 1 or 2 , indicating whether x should be overwritten by A^*x or A'^*x . On the final return from `?lacon`, *kase* will again be 0 .

v On the final return, $v = A^*w$, where $est = \text{norm}(v) / \text{norm}(w)$ (w is not returned).

x On an intermediate return, x should be overwritten by A^*x , if $kase = 1$,
 A'^*x , if $kase = 2$,
(where for complex flavors A' is the conjugate transpose of A), and `?lacon` must be re-called with all the other parameters unchanged.

?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call slacpy( uplo, m, n, a, lda, b, ldb )
call dlacpy( uplo, m, n, a, lda, b, ldb )
call clacpy( uplo, m, n, a, lda, b, ldb )
call zlacpy( uplo, m, n, a, lda, b, ldb )
```

Description

This routine copies all or part of a two-dimensional matrix A to another matrix B .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies the part of the matrix <i>A</i> to be copied to <i>B</i>. If <i>uplo</i> = 'U', the upper triangular part of ; if <i>uplo</i> = 'L', the lower triangular part of <i>A</i>. Otherwise, all of the matrix <i>A</i> is copied.
<i>m</i>	INTEGER. The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i>	REAL for slacpy DOUBLE PRECISION for dlacpy COMPLEX for clacpy COMPLEX*16 for zlacpy. Array <i>a</i>(<i>lda</i>,*), contains the <i>m</i>-by-<i>n</i> matrix <i>A</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. If <i>uplo</i> = 'U', only the upper triangle or trapezoid is accessed; if <i>uplo</i> = 'L', only the lower triangle or trapezoid is accessed.
<i>lda</i>	INTEGER. The first dimension of <i>a</i>; $lda \geq \max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of the output array <i>b</i>; $ldb \geq \max(1, m)$.

Output Parameters

<i>b</i>	REAL for slacpy DOUBLE PRECISION for dlacpy COMPLEX for clacpy COMPLEX*16 for zlacpy. Array <i>b</i>(<i>ldb</i>,*), contains the <i>m</i>-by-<i>n</i> matrix <i>B</i>. The second dimension of <i>b</i> must be at least $\max(1, n)$. On exit, $B = A$ in the locations specified by <i>uplo</i>.

?ladiv

Performs complex division in real arithmetic, avoiding unnecessary overflow.

Syntax

```
call sladiv( a, b, c, d, p, q )
call dladiv( a, b, c, d, p, q )
res = cladiv( x, y )
res = zladiv( x, y )
```

Description

The routines `sladiv/dladiv` perform complex division in real arithmetic as

$$p + iq = \frac{a + ib}{c + id}$$

Complex functions `cladiv/zladiv` compute the result as

$res = x/y$,

where x and y are complex. The computation of x/y will not overflow on an intermediary step unless the results overflows.

Input Parameters

a, b, c, d	REAL for <code>sladiv</code> DOUBLE PRECISION for <code>dladiv</code> The scalars a, b, c , and d in the above expression (for real flavors only).
x, y	COMPLEX for <code>cladiv</code> COMPLEX*16 for <code>zladiv</code> The complex scalars x and y (for complex flavors only).

Output Parameters

p, q	REAL for <code>sladiv</code>

	DOUBLE PRECISION for <code>dladiv</code>
	The scalars p and q in the above expression (for real flavors only).
<code>res</code>	COMPLEX for <code>cladiv</code>
	DOUBLE COMPLEX for <code>zladiv</code>
	Contains the result of division x / y .

?lae2

Computes the eigenvalues of a 2-by-2 symmetric matrix.

Syntax

```
call sla2( a, b, c, rt1, rt2 )
call dla2( a, b, c, rt1, rt2 )
```

Description

The routines `sla2/dla2` compute the eigenvalues of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix}$$

On return, `rt1` is the eigenvalue of larger absolute value, and `rt2` is the eigenvalue of smaller absolute value.

Input Parameters

a, b, c	REAL for <code>sla2</code>
	DOUBLE PRECISION for <code>dla2</code>
	The elements a , b , and c of the 2-by-2 matrix above.

Output Parameters

<code>rt1, rt2</code>	REAL for <code>sla2</code>
	DOUBLE PRECISION for <code>dla2</code>

The computed eigenvalues of larger and smaller absolute value, respectively.

Application Notes

$rt1$ is accurate to a few ulps barring over/underflow. $rt2$ may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute $rt2$ accurately in all cases.

Overflow is possible only if $rt1$ is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds

$underflow\_threshold / macheps$.

?laebz

Computes the number of eigenvalues of a real symmetric tridiagonal matrix which are less than or equal to a given value, and performs other tasks required by the routine ?stebz.

Syntax

```
call slaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d,
e, e2, nval, ab, c, mout, nab, work, iwork, info )
```

```
call dlaebz( ijob, nitmax, n, mmax, minp, nbmin, abstol, reltol, pivmin, d,
e, e2, nval, ab, c, mout, nab, work, iwork, info )
```

Description

The routine ?laebz contains the iteration loops which compute and use the function $n(w)$, which is the count of eigenvalues of a symmetric tridiagonal matrix T less than or equal to its argument w . It performs a choice of two types of loops:

$ijob$	=1, followed by
$ijob$	=2: It takes as input a list of intervals and returns a list of sufficiently small intervals whose union contains the same eigenvalues as the union of the original intervals. The input intervals are $(ab(j,1), ab(j,2)]$, $j=1, \dots, minp$. The output interval $(ab(j,1), ab(j,2)]$ will contain eigenvalues $nab(j,1)+1, \dots, nab(j,2)$, where $1 \leq j \leq mout$.

ijob =3: It performs a binary search in each input interval $(ab(j, 1), ab(j, 2)]$ for a point $w(j)$ such that $n(w(j)) = nval(j)$, and uses $c(j)$ as the starting point of the search. If such a $w(j)$ is found, then on output $ab(j, 1) = ab(j, 2) = w$. If no such $w(j)$ is found, then on output $(ab(j, 1), ab(j, 2)]$ will be a small interval containing the point where $n(w)$ jumps through $nval(j)$, unless that point lies outside the initial interval.

Note that the intervals are in all cases half-open intervals, that is, of the form $(a, b]$, which includes b but not a .

To avoid underflow, the matrix should be scaled so that its largest element is no greater than $overflow^{1/2} * overflow^{1/4}$ in absolute value. To assure the most accurate computation of small eigenvalues, the matrix should be scaled to be not much smaller than that, either.

NOTE. In general, the arguments are not checked for unreasonable values.

Input Parameters

ijob INTEGER. Specifies what is to be done:
 = 1: Compute *nab* for the initial intervals.
 = 2: Perform bisection iteration to find eigenvalues of *T*.
 = 3: Perform bisection iteration to invert $n(w)$, i.e., to find a point which has a specified number of eigenvalues of *T* to its left. Other values will cause ?laebz to return with *info*=-1.

nitmax INTEGER. The maximum number of "levels" of bisection to be performed, i.e., an interval of width *w* will not be made smaller than $2^{-nitmax} * w$. If not all intervals have converged after *nitmax* iterations, then *info* is set to the number of non-converged intervals.

n INTEGER. The dimension *n* of the tridiagonal matrix *T*. It must be at least 1.

mmax INTEGER. The maximum number of intervals. If more than *mmax* intervals are generated, then ?laebz will quit with *info*=*mmax*+1.

<i>minp</i>	INTEGER. The initial number of intervals. It may not be greater than <i>mmax</i> .
<i>nbmin</i>	INTEGER. The smallest number of intervals that should be processed using a vector loop. If zero, then only the scalar loop will be used.
<i>abstol</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. The minimum (absolute) width of an interval. When an interval is narrower than <i>abstol</i> , or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. This must be at least zero.
<i>reltol</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. The minimum relative width of an interval. When an interval is narrower than <i>abstol</i> , or than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least <i>radix*machine epsilon</i> .
<i>pivmin</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. The minimum absolute value of a "pivot" in the Sturm sequence loop. This value must be at least ($\max e(j)**2 * safe\_min$) and at least <i>safe_min</i> , where <i>safe_min</i> is at least the smallest number that can divide one without overflow.
<i>d, e, e2</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. Arrays, dimension (<i>n</i>) each. The array <i>d</i> contains the diagonal elements of the tridiagonal matrix <i>T</i> . The array <i>e</i> contains the off-diagonal elements of the tridiagonal matrix <i>T</i> in positions 1 through <i>n</i> -1. <i>e</i> (<i>n</i>) is arbitrary. The array <i>e2</i> contains the squares of the off-diagonal elements of the tridiagonal matrix <i>T</i> . <i>e2</i> (<i>n</i>) is ignored.
<i>nval</i>	INTEGER. Array, dimension (<i>minp</i>). If <i>ijob</i> =1 or 2, not referenced.

	If $ijob=3$, the desired values of $n(w)$.
<i>ab</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. Array, dimension ($mmax, 2$) The endpoints of the intervals. $ab(j,1)$ is $a(j)$, the left endpoint of the j-th interval, and $ab(j,2)$ is $b(j)$, the right endpoint of the j-th interval.
<i>c</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. Array, dimension ($mmax$) If $ijob=1$, ignored. If $ijob=2$, workspace. If $ijob=3$, then on input $c(j)$ should be initialized to the first search point in the binary search.
<i>nab</i>	INTEGER. Array, dimension ($mmax, 2$) If $ijob=2$, then on input, $nab(i,j)$ should be set. It must satisfy the condition: $n(ab(i,1)) \leq nab(i,1) \leq nab(i,2) \leq n(ab(i,2))$, which means that in interval i only eigenvalues $nab(i,1)+1, \dots, nab(i,2)$ are considered. Usually, $nab(i,j)=n(ab(i,j))$, from a previous call to ?laebz with $ijob=1$. If $ijob=3$, normally, nab should be set to some distinctive value(s) before ?laebz is called.
<i>work</i>	REAL for slaebz DOUBLE PRECISION for dlaebz. Workspace array, dimension ($mmax$).
<i>iwork</i>	INTEGER. Workspace array, dimension ($mmax$).

Output Parameters

<i>nval</i>	The elements of <i>nval</i> will be reordered to correspond with the intervals in <i>ab</i>. Thus, $nval(j)$ on output will not, in general be the same as $nval(j)$ on input, but it will correspond with the interval $(ab(j,1), ab(j,2)]$ on output.

<i>ab</i>	The input intervals will, in general, be modified, split, and reordered by the calculation.
<i>mout</i>	INTEGER. If <i>ijob</i> =1, the number of eigenvalues in the intervals. If <i>ijob</i> =2 or 3, the number of intervals output. If <i>ijob</i> =3, <i>mout</i> will equal <i>minp</i> .
<i>nab</i>	If <i>ijob</i> =1, then on output <i>nab</i> (<i>i,j</i>) will be set to $N(ab(i,j))$. If <i>ijob</i> =2, then on output, <i>nab</i> (<i>i,j</i>) will contain $\max(na(k), \min(nb(k), N(ab(i,j))))$, where <i>k</i> is the index of the input interval that the output interval (<i>ab</i> (<i>j</i> ,1), <i>ab</i> (<i>j</i> ,2)] came from, and <i>na</i> (<i>k</i>) and <i>nb</i> (<i>k</i>) are the input values of <i>nab</i> (<i>k</i> ,1) and <i>nab</i> (<i>k</i> ,2). If <i>ijob</i> =3, then on output, <i>nab</i> (<i>i,j</i>) contains $N(ab(i,j))$, unless $N(w) > nval(i)$ for all search points <i>w</i> , in which case <i>nab</i> (<i>i</i> ,1) will not be modified, i.e., the output value will be the same as the input value (modulo reorderings, see <i>nval</i> and <i>ab</i>), or unless $N(w) < nval(i)$ for all search points <i>w</i> , in which case <i>nab</i> (<i>i</i> ,2) will not be modified.
<i>info</i>	INTEGER. If <i>info</i> = 0 - all intervals converged If <i>info</i> = 1-- <i>mmax</i> - the last <i>info</i> interval did not converge. If <i>info</i> = <i>mmax</i> +1 - more than <i>mmax</i> intervals were generated

Application Notes

This routine is intended to be called only by other LAPACK routines, thus the interface is less user-friendly. It is intended for two purposes:

(a) finding eigenvalues. In this case, *?laebz* should have one or more initial intervals set up in *ab*, and *?laebz* should be called with *ijob*=1. This sets up *nab*, and also counts the eigenvalues. Intervals with no eigenvalues would usually be thrown out at this point. Also, if not all the eigenvalues in an interval *i* are desired, *nab*(*i*,1) can be increased or *nab*(*i*,2) decreased. For example, set *nab*(*i*,1)=*nab*(*i*,2)-1 to get the largest eigenvalue. *?laebz* is then called with *ijob*=2 and *mmax* no smaller than the value of *mout* returned by the call with *ijob*=1. After this (*ijob*=2) call, eigenvalues *nab*(*i*,1)+1 through *nab*(*i*,2) are approximately *ab*(*i*,1) (or *ab*(*i*,2)) to the tolerance specified by *abstol* and *reltol*.

(b) finding an interval $(a', b']$ containing eigenvalues $w(f), \dots, w(l)$. In this case, start with a Gershgorin interval (a, b) . Set up ab to contain 2 search intervals, both initially (a, b) . One $nval$ element should contain $f-1$ and the other should contain l , while c should contain a and b , respectively. $nab(i, 1)$ should be -1 and $nab(i, 2)$ should be $n+1$, to flag an error if the desired interval does not lie in (a, b) . `?laebz` is then called with $ijob=3$. On exit, if $w(f-1) < w(f)$, then one of the intervals -- j -- will have $ab(j, 1)=ab(j, 2)$ and $nab(j, 1)=nab(j, 2)=f-1$, while if, to the specified tolerance, $w(f-k) = \dots = w(f+r)$, $k > 0$ and $r \geq 0$, then the interval will have $n(ab(j, 1))=nab(j, 1)=f-k$ and $n(ab(j, 2))=nab(j, 2)=f+r$. The cases $w(l) < w(l+1)$ and $w(l-r) = \dots = w(l+k)$ are handled similarly.

?laed0

Used by ?stedc. Computes all eigenvalues and corresponding eigenvectors of an unreduced symmetric tridiagonal matrix using the divide and conquer method.

Syntax

```
call slaed0( icompg, qsiz, n, d, e, q, ldq, qstore, ldqs, work, iwork, info
)
call dlaed0( icompg, qsiz, n, d, e, q, ldq, qstore, ldqs, work, iwork, info
)
call claed0( qsiz, n, d, e, q, ldq, qstore, ldqs, rwork, iwork, info )
call zlaed0( qsiz, n, d, e, q, ldq, qstore, ldqs, rwork, iwork, info )
```

Description

Real flavors of this routine compute all eigenvalues and (optionally) corresponding eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Complex flavors `claed0/zlaed0` compute all eigenvalues of a symmetric tridiagonal matrix which is one diagonal block of those from reducing a dense or band Hermitian matrix and corresponding eigenvectors of the dense or band matrix.

Input Parameters

<i>icompg</i>	INTEGER. Used with real flavors only. If <i>icompg</i> = 0, compute eigenvalues only.

If $icompg = 1$, compute eigenvectors of original dense symmetric matrix also.
 On entry, the array q must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
 If $icompg = 2$, compute eigenvalues and eigenvectors of the tridiagonal matrix.

$qsiz$ INTEGER.
 The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if $icompg = 1$).

n INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).

$d, e, rwork$ REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors. Arrays:
 $d(*)$ contains the main diagonal of the tridiagonal matrix. The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of the tridiagonal matrix. The dimension of e must be at least $\max(1, n-1)$.
 $rwork(*)$ is a workspace array used in complex flavors only. The dimension of $rwork$ must be at least $(1 + 3n + 2n \lg(n) + 3n^2)$, where $\lg(n)$ = smallest integer k such that $2^k \geq n$.

$q, qstore$ REAL for slaed0
 DOUBLE PRECISION for dlaed0
 COMPLEX for claed0
 COMPLEX*16 for zlaed0.
 Arrays: $q(ldq, *)$, $qstore(ldqs, *)$. The second dimension of these arrays must be at least $\max(1, n)$.
For real flavors:
 If $icompg = 0$, array q is not referenced.
 If $icompg = 1$, on entry, q is a subset of the columns of the orthogonal matrix used to reduce the full matrix to tridiagonal form corresponding to the subset of the full matrix which is being decomposed at this time.

If $icompq = 2$, on entry, q will be the identity matrix. The array $qstore$ is a workspace array referenced only when $icompq = 1$. Used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

For complex flavors:

On entry, q must contain an $qsiz$ -by- n matrix whose columns are unitarily orthonormal. It is a part of the unitary matrix that reduces the full dense Hermitian matrix to a (reducible) symmetric tridiagonal matrix. The array $qstore$ is a workspace array used to store parts of the eigenvector matrix when the updating matrix multiplies take place.

ldq	INTEGER. The first dimension of the array q ; $ldq \geq \max(1, n)$.
$ldqs$	INTEGER. The first dimension of the array $qstore$; $ldqs \geq \max(1, n)$.
$work$	REAL for slaed0 DOUBLE PRECISION for dlaed0. Workspace array, used in real flavors only. If $icompq = 0$ or 1 , the dimension of $work$ must be at least $(1 + 3n + 2n \lg(n) + 2n^2)$, where $\lg(n) =$ smallest integer k such that $2^k \geq n$. If $icompq = 2$, the dimension of $work$ must be at least $(4n + n^2)$.
$iwork$	INTEGER. Workspace array. For real flavors, if $icompq = 0$ or 1 , and for complex flavors, the dimension of $iwork$ must be at least $(6 + 6n + 5n \lg(n))$. For real flavors, if $icompq = 2$, the dimension of $iwork$ must be at least $(3 + 5n)$.

Output Parameters

d	On exit, contains eigenvalues in ascending order.
e	On exit, the array is destroyed.
q	If $icompq = 2$, on exit, q contains the eigenvectors of the tridiagonal matrix.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i* > 0, the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns *i*/(*n*+1) through mod(*i*, *n*+1).

?laed1

Used by sstedc/dstedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is tridiagonal.

Syntax

```
call slaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
call dlaed1( n, d, q, ldq, indxq, rho, cutpnt, work, iwork, info )
```

Description

The routine ?laed1 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and eigenvectors of a tridiagonal matrix. ?laed7 handles the case in which eigenvalues only or eigenvalues and eigenvectors of a full symmetric matrix (which was reduced to tridiagonal form) are desired.

$$T = Q(\text{in}) * (D(\text{in}) + \text{rho} * Z * Z') * Q'(\text{in}) = Q(\text{out}) * D(\text{out}) * Q'(\text{out})$$

where $Z = Q'u$, u is a vector of length n with ones in the *cutpnt* and (*cutpnt*+1) -th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine ?laed2.

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine ?laed4 (as called by ?laed3). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>d, q, work</i>	REAL for slaed1 DOUBLE PRECISION for dlaed1. Arrays: <i>d</i> (*) contains the eigenvalues of the rank-1-perturbed matrix. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>q</i> (ldq, *) contains the eigenvectors of the rank-1-perturbed matrix. The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $(4n+n^2)$.
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). On entry, the permutation which separately sorts the two subproblems in <i>d</i> into ascending order.
<i>rho</i>	REAL for slaed1 DOUBLE PRECISION for dlaed1. The subdiagonal entry used to create the rank-1 modification. This parameter can be modified by ?laed2, where it is input/output.
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq cutpnt \leq n/2$.
<i>iwork</i>	INTEGER. Workspace array, dimension $(4n)$.

Output Parameters

<i>d</i>	On exit, contains the eigenvalues of the repaired matrix.

<i>q</i>	On exit, <i>q</i> contains the eigenvectors of the repaired tridiagonal matrix.
<i>indxq</i>	On exit, contains the permutation which will reintegrate the subproblems back into sorted order, that is, <i>d</i> (<i>indxq</i> (<i>i</i> = 1, <i>n</i>)) will be in ascending order.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, an eigenvalue did not converge.

?laed2

Used by sstedc/dstedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is tridiagonal.

Syntax

```
call slaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc,
            indxpr, coltyp, info )
```

```
call dlaed2( k, n, n1, d, q, ldq, indxq, rho, z, dlamda, w, q2, indx, indxc,
            indxpr, coltyp, info )
```

Description

The routine ?laed2 merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny entry in the *z* vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

<i>k</i>	INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation ($0 \leq k \leq n$).
<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>n1</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.

<i>d, q, z</i>	REAL for slaed2 DOUBLE PRECISION for dlaed2. Arrays: <i>d</i>(*) contains the eigenvalues of the two submatrices to be combined. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>q</i>(ldq, *) contains the eigenvectors of the two submatrices in the two square blocks with corners at (1,1), (n1,n1) and (n1+1,n1+1), (n,n). The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>z</i>(*) contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i>; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (n). On entry, the permutation which separately sorts the two subproblems in <i>d</i> into ascending order. Note that elements in the second half of this permutation must first have <i>n1</i> added to their values.
<i>rho</i>	REAL for slaed2 DOUBLE PRECISION for dlaed2. On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.
<i>indx, indxp</i>	INTEGER. Workspace arrays, dimension (n) each. Array <i>indx</i> contains the permutation used to sort the contents of <i>dlamda</i> into ascending order. Array <i>indxp</i> contains the permutation used to place deflated values of <i>d</i> at the end of the array. <i>indxp</i>(1:k) points to the nondeflated <i>d</i>-values and <i>indxp</i>(k+1:n) points to the deflated eigenvalues.
<i>coltyp</i>	INTEGER. Workspace array, dimension (n). During execution, a label which will indicate which of the following types a column in the <i>q2</i> matrix is: 1 : non-zero in the upper half only;

2 : dense;
 3 : non-zero in the lower half only;
 4 : deflated.

Output Parameters

d On exit, *d* contains the trailing $(n-k)$ updated eigenvalues (those which were deflated) sorted into increasing order.

q On exit, *q* contains the trailing $(n-k)$ updated eigenvectors (those which were deflated) in its last $n-k$ columns.

z On exit, *z* content is destroyed by the updating process.

indxq Destroyed on exit.

rho On exit, *rho* has been modified to the value required by ?laed3.

dlamda, *w*, *q2* REAL for slaed2
 DOUBLE PRECISION for dlaed2.
 Arrays: *dlamda*(*n*), *w*(*n*), *q2*($n1^2 + (n-n1)^2$).
 The array *dlamda* contains a copy of the first *k* eigenvalues which is used by ?laed3 to form the secular equation.
 The array *w* contains the first *k* values of the final deflation-altered *z*-vector which is passed to ?laed3.
 The array *q2* contains a copy of the first *k* eigenvectors which is used by ?laed3 in a matrix multiply (sgemm/dgemm) to solve for the new eigenvectors.

indx INTEGER. Array, dimension (*n*).
 The permutation used to arrange the columns of the deflated *q* matrix into three groups: the first group contains non-zero elements only at and above *n1*, the second contains non-zero elements only below *n1*, and the third is dense.

coltyp On exit, *coltyp*(*i*) is the number of columns of type *i*, for *i*=1 to 4 only (see the definition of types in the description of *coltyp* in *Input Parameters*).

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?laed3

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is tridiagonal.

Syntax

```
call slaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
call dlaed3( k, n, n1, d, q, ldq, rho, dlamda, q2, indx, ctot, w, s, info )
```

Description

The routine ?laed3 finds the roots of the secular equation, as defined by the values in *d*, *w*, and *rho*, between 1 and *k*.

It makes the appropriate calls to ?laed4 and then updates the eigenvectors by multiplying the matrix of eigenvectors of the pair of eigensystems being combined by the matrix of eigenvectors of the *k*-by-*k* system which is solved here.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but none are known.

Input Parameters

<i>k</i>	INTEGER. The number of terms in the rational function to be solved by ?laed4 ($k \geq 0$).
<i>n</i>	INTEGER. The number of rows and columns in the <i>q</i> matrix. $n \geq k$ (deflation may result in $n > k$).
<i>n1</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix; $\min(1, n) \leq n1 \leq n/2$.
<i>q</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. Array <i>q</i> (<i>ldq</i> , *). The second dimension of <i>q</i> must be at least $\max(1, n)$. Initially, the first <i>k</i> columns of this array are used as workspace.

<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>rho</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
<i>dlambda, q2, w</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. Arrays: <i>dlambda(k)</i> , <i>q2(ldq2, *)</i> , <i>w(k)</i> . The first <i>k</i> elements of the array <i>dlambda</i> contain the old roots of the deflated updating problem. These are the poles of the secular equation. The first <i>k</i> columns of the array <i>q2</i> contain the non-deflated eigenvectors for the split problem. The second dimension of <i>q2</i> must be at least $\max(1, n)$. The first <i>k</i> elements of the array <i>w</i> contain the components of the deflation-adjusted updating vector.
<i>indx</i>	INTEGER. Array, dimension (<i>n</i>). The permutation used to arrange the columns of the deflated <i>q</i> matrix into three groups (see ?laed2). The rows of the eigenvectors found by ?laed4 must be likewise permuted before the matrix multiply can take place.
<i>ctot</i>	INTEGER. Array, dimension (4). A count of the total number of the various types of columns in <i>q</i> , as described in <i>indx</i> . The fourth column type is any column which has been deflated.
<i>s</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3. Workspace array, dimension $(n1+1)*k$. Will contain the eigenvectors of the repaired matrix which will be multiplied by the previously accumulated eigenvectors to update the system.

Output Parameters

<i>d</i>	REAL for slaed3 DOUBLE PRECISION for dlaed3.

	Array, dimension at least $\max(1, n)$.
	$d(i)$ contains the updated eigenvalues for $1 \leq i \leq k$.
q	On exit, the columns 1 to k of q contain the updated eigenvectors.
$d\lambda mda$	May be changed on output by having lowest order bit set to zero on Cray X-MP, Cray Y-MP, Cray-2, or Cray C-90, as described above.
w	Destroyed on exit.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, an eigenvalue did not converge.

?laed4

Used by sstedc/dstedc. Finds a single root of the secular equation.

Syntax

```
call slaed4( n, i, d, z, delta, rho, dlam, info )
call dlaed4( n, i, d, z, delta, rho, dlam, info )
```

Description

This subroutine computes the i -th updated eigenvalue of a symmetric rank-one modification to a diagonal matrix whose elements are given in the array d , and that

$$D(i) < D(j) \text{ for } i < j$$

and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(D) + \rho * Z * \text{transpose}(Z).$$

where we assume the Euclidean norm of Z is 1.

The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

<i>n</i>	INTEGER. The length of all arrays.
<i>i</i>	INTEGER. The index of the eigenvalue to be computed; $1 \leq i \leq n$.
<i>d</i> , <i>z</i>	REAL for slaed4 DOUBLE PRECISION for dlaed4 Arrays, dimension (<i>n</i>) each. The array <i>d</i> contains the original eigenvalues. It is assumed that they are in order, $d(i) < d(j)$ for $i < j$. The array <i>z</i> contains the components of the updating vector <i>Z</i> .
<i>rho</i>	REAL for slaed4 DOUBLE PRECISION for dlaed4 The scalar in the symmetric updating formula.

Output Parameters

<i>delta</i>	REAL for slaed4 DOUBLE PRECISION for dlaed4 Array, dimension (<i>n</i>). If $n \neq 1$, <i>delta</i> contains $(d(j) - \lambda_i)$ in its <i>j</i> -th component. If $n = 1$, then $delta(1) = 1$. The vector <i>delta</i> contains the information necessary to construct the eigenvectors.
<i>diam</i>	REAL for slaed4 DOUBLE PRECISION for dlaed4 The computed λ_i , the <i>i</i> -th updated eigenvalue.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = 1, the updating process failed.

slaed5

Used by sstedc/dstedc. Solves the 2-by-2 secular equation.

Syntax

```
call slaed5( i, d, z, delta, rho, dlam )
call dlaed5( i, d, z, delta, rho, dlam )
```

Description

This subroutine computes the i -th eigenvalue of a symmetric rank-one modification of a 2-by-2 diagonal matrix

$$\text{diag}(D) + \rho * Z * \text{transpose}(Z).$$

The diagonal elements in the array D are assumed to satisfy

$$D(i) < D(j) \text{ for } i < j.$$

We also assume $\rho > 0$ and that the Euclidean norm of the vector Z is one.

Input Parameters

i	INTEGER. The index of the eigenvalue to be computed; $1 \leq i \leq 2$.
d, z	REAL for slaed5 DOUBLE PRECISION for dlaed5 Arrays, dimension (2) each. The array d contains the original eigenvalues. It is assumed that $d(1) < d(2)$. The array z contains the components of the updating vector.
ρ	REAL for slaed5 DOUBLE PRECISION for dlaed5 The scalar in the symmetric updating formula.

Output Parameters

δ	REAL for slaed5 DOUBLE PRECISION for dlaed5 Array, dimension (2).

The vector *delta* contains the information necessary to construct the eigenvectors.

diam REAL for slaed5
 DOUBLE PRECISION for dlaed5
 The computed *lambda_i*, the *i*-th updated eigenvalue.

?laed6

Used by sstedc/dstedc. Computes one Newton step in solution of the secular equation.

Syntax

```
call slaed6( kniter, orgati, rho, d, z, finit, tau, info )
call dlaed6( kniter, orgati, rho, d, z, finit, tau, info )
```

Description

This routine computes the positive or negative root (closest to the origin) of

$$f(x) = rho + \frac{z(1)}{d(1) - x} + \frac{z(2)}{d(2) - x} + \frac{z(3)}{d(3) - x}$$

It is assumed that if *orgati* = .TRUE. the root is between *d*(2) and *d*(3); otherwise it is between *d*(1) and *d*(2). This routine is called by ?laed4 when necessary. In most cases, the root sought is the smallest in magnitude, though it might not be in some extremely rare situations.

Input Parameters

kniter INTEGER.
 Refer to ?laed4 for its significance.

orgati LOGICAL.
 If *orgati* = .TRUE., the needed root is between *d*(2) and *d*(3); otherwise it is between *d*(1) and *d*(2). See ?laed4 for further details.

rho REAL for slaed6
 DOUBLE PRECISION for dlaed6

<i>d, z</i>	Refer to the equation for $f(x)$ above. REAL for slaed6 DOUBLE PRECISION for dlaed6 Arrays, dimension (3) each. The array <i>d</i> satisfies $d(1) < d(2) < d(3)$. Each of the elements in the array <i>z</i> must be positive.
<i>finit</i>	REAL for slaed6 DOUBLE PRECISION for dlaed6 The value of $f(x)$ at 0. It is more accurate than the one evaluated inside this routine (if someone wants to do so).

Output Parameters

<i>tau</i>	REAL for slaed6 DOUBLE PRECISION for dlaed6 The root of the equation for $f(x)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = 1, failure to converge.

?laed7

Used by ?stedc. Computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. Used when the original matrix is dense.

Syntax

```
call slaed7( icompg, n, qsiz, tlvl, curlvl, curpbm, d, q, ldq, indxq, rho,
cutpnt, qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info
)

call dlaed7( icompg, n, qsiz, tlvl, curlvl, curpbm, d, q, ldq, indxq, rho,
cutpnt, qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, iwork, info
)

call claed7( n, cutpnt, qsiz, tlvl, curlvl, curpbm, d, q, ldq, rho, indxq,
qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info
)

call zlaed7( n, cutpnt, qsiz, tlvl, curlvl, curpbm, d, q, ldq, rho, indxq,
qstore, qptr, prmptr, perm, givptr, givcol, givnum, work, rwork, iwork, info
)
```

Description

The routine ?laed7 computes the updated eigensystem of a diagonal matrix after modification by a rank-one symmetric matrix. This routine is used only for the eigenproblem which requires all eigenvalues and optionally eigenvectors of a dense symmetric/Hermitian matrix that has been reduced to tridiagonal form. For real flavors, slaed1/dlaed1 handles the case in which all eigenvalues and eigenvectors of a symmetric tridiagonal matrix are desired.

$$T = Q(\text{in}) * (D(\text{in}) + \rho * Z * Z') * Q'(\text{in}) = Q(\text{out}) * D(\text{out}) * Q'(\text{out})$$

where $Z = Q' * u$, u is a vector of length n with ones in the cutpnt and $(\text{cutpnt} + 1)$ -th elements and zeros elsewhere. The eigenvectors of the original matrix are stored in Q , and the eigenvalues are in D . The algorithm consists of three stages:

The first stage consists of deflating the size of the problem when there are multiple eigenvalues or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine slaed8/dlaed8 (for real flavors) or by the routine slaed2/dlaed2 (for complex flavors).

The second stage consists of calculating the updated eigenvalues. This is done by finding the roots of the secular equation via the routine ?laed4 (as called by ?laed9 or ?laed3). This routine also calculates the eigenvectors of the current problem.

The final stage consists of computing the updated eigenvectors directly using the updated eigenvalues. The eigenvectors for the current problem are multiplied with the eigenvectors from the overall problem.

Input Parameters

<i>icompg</i>	INTEGER. Used with real flavors only. If <i>icompg</i> = 0, compute eigenvalues only. If <i>icompg</i> = 1, compute eigenvectors of original dense symmetric matrix also. On entry, the array <i>q</i> must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>cutpnt</i>	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq \text{cutpnt} \leq n$.
<i>qsiz</i>	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if <i>icompg</i> = 1).
<i>tlvls</i>	INTEGER. The total number of merging levels in the overall divide and conquer tree.
<i>curlvl</i>	INTEGER. The current level in the overall merge routine, $0 \leq \text{curlvl} \leq \text{tlvls}$.
<i>curpbm</i>	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
<i>d</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension at least $\max(1, n)$. Array <i>d</i>(*) contains the eigenvalues of the rank-1-perturbed matrix.

<i>q, work</i>	REAL for slaed7 DOUBLE PRECISION for dlaed7 COMPLEX for claed7 COMPLEX*16 for zlaed7. Arrays: <i>q(ldq, *)</i> contains the the eigenvectors of the rank-1-perturbed matrix. The second dimension of <i>q</i> must be at least $\max(1, n)$. <i>work(*)</i> is a workspace array, dimension at least $(3n+qsiz*n)$ for real flavors and at least $(qsiz*n)$ for complex flavors.
<i>ldq</i>	INTEGER. The first dimension of the array <i>q</i> ; $ldq \geq \max(1, n)$.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). Contains the permutation that separately sorts the two sub-problems in <i>d</i> into ascending order.
<i>rho</i>	REAL for slaed7 /claed7 DOUBLE PRECISION for dlaed7/zlaed7. The subdiagonal element used to create the rank-1 modification.
<i>qstore</i>	REAL for slaed7/claed7 DOUBLE PRECISION for dlaed7/zlaed7. Array, dimension (n^2+1). Serves also as output parameter. Stores eigenvectors of submatrices encountered during divide and conquer, packed together. <i>qp</i><i>tr</i> points to beginning of the submatrices.
<i>qp</i> <i>tr</i>	INTEGER. Array, dimension $(n+2)$. Serves also as output parameter. List of indices pointing to beginning of submatrices stored in <i>qstore</i>. The submatrices are numbered starting at the bottom left of the divide and conquer tree, from left to right and bottom to top.
<i>prmp</i> <i>tr</i> , <i>perm</i> , <i>givp</i> <i>tr</i>	INTEGER. Arrays, dimension $(n \lg n)$ each. The array <i>prmp</i><i>tr</i>(*) contains a list of pointers which indicate where in <i>perm</i> a level's permutation is stored. <i>prmp</i><i>tr</i>(<i>i</i>+1) - <i>prmp</i><i>tr</i>(<i>i</i>) indicates the size of the permutation and also the size of the full, non-deflated problem.

The array *perm*(*) contains the permutations (from deflation and sorting) to be applied to each eigenblock. This parameter can be modified by *?laed8*, where it is output. The array *givptr*(*) contains a list of pointers which indicate where in *givcol* a level's Givens rotations are stored. *givptr*(i+1) - *givptr*(i) indicates the number of Givens rotations.

<i>givcol</i>	INTEGER. Array, dimension (2, <i>n lg n</i>). Each pair of numbers indicates a pair of columns to take place in a Givens rotation.
<i>givnum</i>	REAL for <i>slaed7/claed7</i> DOUBLE PRECISION for <i>dlaed7/zlaed7</i> . Array, dimension (2, <i>n lg n</i>). Each number indicates the <i>s</i> value to be used in the corresponding Givens rotation.
<i>iwork</i>	INTEGER. Workspace array, dimension (4 <i>n</i>).
<i>rwork</i>	REAL for <i>claed7</i> DOUBLE PRECISION for <i>zlaed7</i> . Workspace array, dimension (3 <i>n</i> +2 <i>qsiz</i> * <i>n</i>). Used in complex flavors only.

Output Parameters

<i>d</i>	On exit, contains the eigenvalues of the repaired matrix.
<i>q</i>	On exit, <i>q</i> contains the eigenvectors of the repaired tridiagonal matrix.
<i>indxq</i>	INTEGER. Array, dimension (<i>n</i>). Contains the permutation that reintegrates the subproblems back into a sorted order, that is, <i>d</i> (<i>indxq</i> (i = 1, <i>n</i>)) will be in the ascending order.
<i>rho</i>	This parameter can be modified by <i>?laed8</i> , where it is input/output.
<i>prmptr, perm, givptr</i>	INTEGER. Arrays, dimension (<i>n lg n</i>) each. The array <i>prmptr</i> contains an updated list of pointers. The array <i>perm</i> contains an updated permutation. The array <i>givptr</i> contains an updated list of pointers.

<i>givcol</i>	This parameter can be modified by <code>?laed8</code> , where it is output.
<i>givnum</i>	This parameter can be modified by <code>?laed8</code> , where it is output.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, an eigenvalue did not converge.

?laed8

Used by ?stedc. Merges eigenvalues and deflates secular equation. Used when the original matrix is dense.

Syntax

```
call slaed8( icompg, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda,
q2, ldq2, w, perm, givptr, givcol, givnum, indxp, indx, info )
call dlaed8( icompg, k, n, qsiz, d, q, ldq, indxq, rho, cutpnt, z, dlamda,
q2, ldq2, w, perm, givptr, givcol, givnum, indxp, indx, info )
call claed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indxp,
indx, indxq, perm, givptr, givcol, givnum, info )
call zlaed8( k, n, qsiz, q, ldq, d, rho, cutpnt, z, dlamda, q2, ldq2, w, indxp,
indx, indxq, perm, givptr, givcol, givnum, info )
```

Description

This routine merges the two sets of eigenvalues together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more eigenvalues are close together or if there is a tiny element in the *z* vector. For each such occurrence the order of the related secular equation problem is reduced by one.

Input Parameters

<i>icompg</i>	INTEGER. Used with real flavors only. If <i>icompg</i> = 0, compute eigenvalues only. If <i>icompg</i> = 1, compute eigenvectors of original dense symmetric matrix also.

	On entry, the array q must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form.
n	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
$cutpnt$	INTEGER. The location of the last eigenvalue in the leading sub-matrix. $\min(1, n) \leq cutpnt \leq n$.
$qsiz$	INTEGER. The dimension of the orthogonal/unitary matrix used to reduce the full matrix to tridiagonal form; $qsiz \geq n$ (for real flavors, $qsiz \geq n$ if $icompg = 1$).
d, z	REAL for slaed8/claed8 DOUBLE PRECISION for dlaed8/zlaed8. Arrays, dimension at least $\max(1, n)$ each. The array $d(*)$ contains the eigenvalues of the two submatrices to be combined. On entry, $z(*)$ contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix). The contents of z are destroyed by the updating process.
q	REAL for slaed8 DOUBLE PRECISION for dlaed8 COMPLEX for claed8 COMPLEX*16 for zlaed8. Array $q(ldq, *)$. The second dimension of q must be at least $\max(1, n)$. On entry, q contains the eigenvectors of the partially solved system which has been previously updated in matrix multiplies with other partially solved eigensystems. For real flavors, If $icompg = 0$, q is not referenced.
ldq	INTEGER. The first dimension of the array q ; $ldq \geq \max(1, n)$.
$ldq2$	INTEGER. The first dimension of the output array $q2$; $ldq2 \geq \max(1, n)$.
$indxq$	INTEGER. Array, dimension (n).

The permutation that separately sorts the two sub-problems in d into ascending order. Note that elements in the second half of this permutation must first have *cutpnt* added to their values in order to be accurate.

rho

REAL for slaed8/claed8

DOUBLE PRECISION for dlaed8/zlaed8.

On entry, the off-diagonal element associated with the rank-1 cut which originally split the two submatrices which are now being recombined.

Output Parameters

k

INTEGER. The number of non-deflated eigenvalues, and the order of the related secular equation.

d

On exit, contains the trailing $(n-k)$ updated eigenvalues (those which were deflated) sorted into increasing order.

z

On exit, the updating process destroys the contents of *z*.

q

On exit, *q* contains the trailing $(n-k)$ updated eigenvectors (those which were deflated) in its last $(n-k)$ columns.

indxq

INTEGER. Array, dimension (n) .

The permutation of merged eigenvalues set.

rho

On exit, *rho* has been modified to the value required by ?laed3.

dlamda, w

REAL for slaed8/claed8

DOUBLE PRECISION for dlaed8/zlaed8.

Arrays, dimension (n) each. The array *dlamda*(*) contains a copy of the first k eigenvalues which will be used by ?laed3 to form the secular equation.

The array *w*(*) will hold the first k values of the final deflation-altered *z*-vector and will be passed to ?laed3.

q2

REAL for slaed8

DOUBLE PRECISION for dlaed8

COMPLEX for claed8

COMPLEX*16 for zlaed8.

Array

q2(*ldq2*, *). The second dimension of *q2* must be at least $\max(1, n)$.

	Contains a copy of the first k eigenvectors which will be used by <code>slaed7/dlaed7</code> in a matrix multiply (<code>sgemm/dgemm</code>) to update the new eigenvectors. For real flavors, If <code>icompg</code> = 0, <code>q2</code> is not referenced.
<code>indxp, indx</code>	INTEGER. Workspace arrays, dimension (n) each. The array <code>indxp(*)</code> will contain the permutation used to place deflated values of d at the end of the array. On output, <code>indxp(1:k)</code> points to the nondeflated d -values and <code>indxp(k+1:n)</code> points to the deflated eigenvalues. The array <code>indx(*)</code> will contain the permutation used to sort the contents of d into ascending order.
<code>perm</code>	INTEGER. Array, dimension (n). Contains the permutations (from deflation and sorting) to be applied to each eigenblock.
<code>givptr</code>	INTEGER. Contains the number of Givens rotations which took place in this subproblem.
<code>givcol</code>	INTEGER. Array, dimension (2, n). Each pair of numbers indicates a pair of columns to take place in a Givens rotation.
<code>givnum</code>	REAL for <code>slaed8/claed8</code> DOUBLE PRECISION for <code>dlaed8/zlaed8</code> . Array, dimension (2, n). Each number indicates the s value to be used in the corresponding Givens rotation.
<code>info</code>	INTEGER. If <code>info</code> = 0, the execution is successful. If <code>info</code> = $-i$, the i -th parameter had an illegal value.

slaed9

Used by sstedc/dstedc. Finds the roots of the secular equation and updates the eigenvectors. Used when the original matrix is dense.

Syntax

```
call slaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
call dlaed9( k, kstart, kstop, n, d, q, ldq, rho, dlamda, w, s, lds, info )
```

Description

This routine finds the roots of the secular equation, as defined by the values in d , z , and ρ , between $kstart$ and $kstop$. It makes the appropriate calls to slaed4/dlaed4 and then stores the new matrix of eigenvectors for use in calculating the next level of z vectors.

Input Parameters

k	INTEGER. The number of terms in the rational function to be solved by slaed4/dlaed4 ($k \geq 0$).
$kstart, kstop$	INTEGER. The updated eigenvalues $\lambda(i)$, $kstart \leq i \leq kstop$ are to be computed. $1 \leq kstart \leq kstop \leq k$.
n	INTEGER. The number of rows and columns in the Q matrix. $n \geq k$ (deflation may result in $n > k$).
q	REAL for slaed9 DOUBLE PRECISION for dlaed9. Workspace array, dimension ($ldq, *$). The second dimension of q must be at least $\max(1, n)$.
ldq	INTEGER. The first dimension of the array q ; $ldq \geq \max(1, n)$.
ρ	REAL for slaed9 DOUBLE PRECISION for dlaed9 The value of the parameter in the rank one update equation. $\rho \geq 0$ required.
$dlamda, w$	REAL for slaed9

DOUBLE PRECISION for dlaed9

Arrays, dimension (k) each. The first k elements of the array $d\lambda mda(*)$ contain the old roots of the deflated updating problem. These are the poles of the secular equation. The first k elements of the array $w(*)$ contain the components of the deflation-adjusted updating vector.

lds

INTEGER. The first dimension of the output array s ; $lds \geq \max(1, k)$.

Output Parameters

d

REAL for slaed9

DOUBLE PRECISION for dlaed9

Array, dimension (n). Elements in $d(i)$ are not referenced for $1 \leq i < kstart$ or $kstop < i \leq n$.

s

REAL for slaed9

DOUBLE PRECISION for dlaed9.

Array, dimension ($lds, *$).

The second dimension of s must be at least $\max(1, k)$. Will contain the eigenvectors of the repaired matrix which will be stored for subsequent z vector calculation and multiplied by the previously accumulated eigenvectors to update the system.

$d\lambda mda$

On exit, the value is modified to make sure all $d\lambda mda(i) - d\lambda mda(j)$ can be computed with high relative accuracy, barring overflow and underflow.

w

Destroyed on exit.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, the eigenvalue did not converge.

?laeda

Used by ?stedc. Computes the Z vector determining the rank-one modification of the diagonal matrix. Used when the original matrix is dense.

Syntax

```
call slaeda( n, tlvl, curlvl, curpbm, prmptr, perm, givptr, givcol, givnum,
q, qptr, z, ztemp, info )
call dlaeda( n, tlvl, curlvl, curpbm, prmptr, perm, givptr, givcol, givnum,
q, qptr, z, ztemp, info )
```

Description

The routine ?laeda computes the Z vector corresponding to the merge step in the *curlvl*-th step of the merge process with *tlvl* steps for the *curpbm*-th problem.

Input Parameters

<i>n</i>	INTEGER. The dimension of the symmetric tridiagonal matrix ($n \geq 0$).
<i>tlvl</i>	INTEGER. The total number of merging levels in the overall divide and conquer tree.
<i>curlvl</i>	INTEGER. The current level in the overall merge routine, $0 \leq \text{curlvl} \leq \text{tlvl}$.
<i>curpbm</i>	INTEGER. The current problem in the current level in the overall merge routine (counting from upper left to lower right).
<i>prmptr</i> , <i>perm</i> , <i>givptr</i>	INTEGER. Arrays, dimension $(n \lg n)$ each. The array <i>prmptr</i> (*) contains a list of pointers which indicate where in <i>perm</i> a level's permutation is stored. <i>prmptr</i> (<i>i</i> +1) - <i>prmptr</i> (<i>i</i>) indicates the size of the permutation and also the size of the full, non-deflated problem. The array <i>perm</i> (*) contains the permutations (from deflation and sorting) to be applied to each eigenblock.

	The array <i>givptr</i>(*) contains a list of pointers which indicate where in <i>givcol</i> a level's Givens rotations are stored. <i>givptr</i>(i+1) - <i>givptr</i>(i) indicates the number of Givens rotations.
<i>givcol</i>	INTEGER. Array, dimension (2, <i>n lg n</i>). Each pair of numbers indicates a pair of columns to take place in a Givens rotation.
<i>givnum</i>	REAL for slaeda DOUBLE PRECISION for dlaeda. Array, dimension (2, <i>n lg n</i>). Each number indicates the <i>s</i> value to be used in the corresponding Givens rotation.
<i>q</i>	REAL for slaeda DOUBLE PRECISION for dlaeda. Array, dimension (<i>n</i>²). Contains the square eigenblocks from previous levels, the starting positions for blocks are given by <i>qptr</i>.
<i>qptr</i>	INTEGER. Array, dimension (<i>n</i>+2). Contains a list of pointers which indicate where in <i>q</i> an eigenblock is stored. <i>sqrt</i>(<i>qptr</i>(i+1) - <i>qptr</i>(i)) indicates the size of the block.
<i>ztemp</i>	REAL for slaeda DOUBLE PRECISION for dlaeda. Workspace array, dimension (<i>n</i>).

Output Parameters

<i>z</i>	REAL for slaeda DOUBLE PRECISION for dlaeda. Array, dimension (<i>n</i>). Contains the updating vector (the last row of the first sub-eigenvector matrix and the first row of the second sub-eigenvector matrix).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.

?laein

Computes a specified right or left eigenvector of an upper Hessenberg matrix by inverse iteration.

Syntax

```
call slaein( rightv, noinit, n, h, ldh, wr, wi, vr, vi, b, ldb, work, eps3,
smlnum, bignum, info )

call dlaein( rightv, noinit, n, h, ldh, wr, wi, vr, vi, b, ldb, work, eps3,
smlnum, bignum, info )

call claein( rightv, noinit, n, h, ldh, w, v, b, ldb, rwork, eps3, smlnum,
info )

call zlaein( rightv, noinit, n, h, ldh, w, v, b, ldb, rwork, eps3, smlnum,
info )
```

Description

The routine ?laein uses inverse iteration to find a right or left eigenvector corresponding to the eigenvalue (wr, wi) of a real upper Hessenberg matrix H (for real flavors slaein/dlaein) or to the eigenvalue w of a complex upper Hessenberg matrix H (for complex flavors claein/zlaein).

Input Parameters

<i>rightv</i>	LOGICAL. If <i>rightv</i> = .TRUE., compute right eigenvector; if <i>rightv</i> = .FALSE., compute left eigenvector.
<i>noinit</i>	LOGICAL. If <i>noinit</i> = .TRUE., no initial vector is supplied in (<i>vr</i> , <i>vi</i>) or in <i>v</i> (for complex flavors); if <i>noinit</i> = .FALSE., initial vector is supplied in (<i>vr</i> , <i>vi</i>) or in <i>v</i> (for complex flavors).
<i>n</i>	INTEGER. The order of the matrix H ($n \geq 0$).
<i>h</i>	REAL for slaein DOUBLE PRECISION for dlaein COMPLEX for claein COMPLEX*16 for zlaein.

	Array $h(ldh, *)$. The second dimension of h must be at least $\max(1, n)$. Contains the upper Hessenberg matrix H.
ldh	INTEGER. The first dimension of the array h; $ldh \geq \max(1, n)$.
wr, wi	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code>. The real and imaginary parts of the eigenvalue of H whose corresponding right or left eigenvector is to be computed (for real flavors of the routine).
w	COMPLEX for <code>claein</code> COMPLEX*16 for <code>zlaein</code>. The eigenvalue of H whose corresponding right or left eigenvector is to be computed (for complex flavors of the routine).
vr, vi	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code>. Arrays, dimension (n) each. Used for real flavors only. On entry, if <code>noinit</code> = <code>.FALSE.</code> and $wi = 0.0$, vr must contain a real starting vector for inverse iteration using the real eigenvalue wr; if <code>noinit</code> = <code>.FALSE.</code> and $wi \neq 0.0$, vr and vi must contain the real and imaginary parts of a complex starting vector for inverse iteration using the complex eigenvalue (wr, wi); otherwise vr and vi need not be set.
v	COMPLEX for <code>claein</code> COMPLEX*16 for <code>zlaein</code>. Array, dimension (n). Used for complex flavors only. On entry, if <code>noinit</code> = <code>.FALSE.</code>, v must contain a starting vector for inverse iteration; otherwise v need not be set.
b	REAL for <code>slaein</code> DOUBLE PRECISION for <code>dlaein</code> COMPLEX for <code>claein</code> COMPLEX*16 for <code>zlaein</code>. Workspace array $b(l db, *)$. The second dimension of b must be at least $\max(1, n)$.

<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i>; $ldb \geq n+1$ for real flavors; $ldb \geq \max(1, n)$ for complex flavors.
<i>work</i>	REAL for slaein DOUBLE PRECISION for dlaein. Workspace array, dimension (<i>n</i>). Used for real flavors only.
<i>rwork</i>	REAL for claein DOUBLE PRECISION for zlaein. Workspace array, dimension (<i>n</i>). Used for complex flavors only.
<i>eps3, smlnum</i>	REAL for slaein/claein DOUBLE PRECISION for dlaein/zlaein. <i>eps3</i> is a small machine-dependent value which is used to perturb close eigenvalues, and to replace zero pivots. <i>smlnum</i> is a machine-dependent value close to underflow threshold.
<i>bignum</i>	REAL for slaein DOUBLE PRECISION for dlaein. <i>bignum</i> is a machine-dependent value close to overflow threshold. Used for real flavors only.

Output Parameters

<i>vr, vi</i>	On exit, if $w_i = 0.0$ (real eigenvalue), <i>vr</i> contains the computed real eigenvector; if $w_i \neq 0.0$ (complex eigenvalue), <i>vr</i> and <i>vi</i> contain the real and imaginary parts of the computed complex eigenvector. The eigenvector is normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (<i>x,y</i>) is taken to be $x + y$. <i>vi</i> is not referenced if $w_i = 0.0$.
<i>v</i>	On exit, <i>v</i> contains the computed eigenvector, normalized so that the component of largest magnitude has magnitude 1; here the magnitude of a complex number (<i>x,y</i>) is taken to be $x + y$.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = 1, inverse iteration did not converge. For real flavors, *vr* is set to the last iterate, and so is *vi*, if *wi* ≠ 0.0. For complex flavors, *v* is set to the last iterate.

?laev2

Computes the eigenvalues and eigenvectors of a 2-by-2 symmetric/Hermitian matrix.

Syntax

call slaev2(*a*, *b*, *c*, *rt1*, *rt2*, *cs1*, *sn1*)

call dlaev2(*a*, *b*, *c*, *rt1*, *rt2*, *cs1*, *sn1*)

call claev2(*a*, *b*, *c*, *rt1*, *rt2*, *cs1*, *sn1*)

call zlaev2(*a*, *b*, *c*, *rt1*, *rt2*, *cs1*, *sn1*)

Description

This routine performs the eigendecomposition of a 2-by-2 symmetric matrix

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix} \text{ (for slaev2/dlaev2) or Hermitian matrix } \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix}$$

(for claev2/zlaev2).

On return, *rt1* is the eigenvalue of larger absolute value, *rt2* of smaller absolute value, and (*cs1*, *sn1*) is the unit right eigenvector for *rt1*, giving the decomposition

$$\begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ b & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for slaev2/dlaev2),

or

$$\begin{bmatrix} cs1 & \text{conjg}(sn1) \\ -sn1 & cs1 \end{bmatrix} \cdot \begin{bmatrix} a & b \\ \text{conjg}(b) & c \end{bmatrix} \cdot \begin{bmatrix} cs1 & -\text{conjg}(sn1) \\ sn1 & cs1 \end{bmatrix} = \begin{bmatrix} rt1 & 0 \\ 0 & rt2 \end{bmatrix}$$

(for `claev2/zlaev2`).

Input Parameters

a, b, c REAL for `slaev2`
 DOUBLE PRECISION for `dlaev2`
 COMPLEX for `claev2`
 COMPLEX*16 for `zlaev2`.
 Elements of the input matrix.

Output Parameters

rt1, rt2 REAL for `slaev2/claev2`
 DOUBLE PRECISION for `dlaev2/zlaev2`.
 Eigenvalues of larger and smaller absolute value,
 respectively.

cs1 REAL for `slaev2/claev2`
 DOUBLE PRECISION for `dlaev2/zlaev2`.

sn1 REAL for `slaev2`
 DOUBLE PRECISION for `dlaev2`
 COMPLEX for `claev2`
 COMPLEX*16 for `zlaev2`.
 The vector (*cs1, sn1*) is the unit right eigenvector for *rt1*.

Application Notes

rt1 is accurate to a few ulps barring over/underflow. *rt2* may be inaccurate if there is massive cancellation in the determinant $a*c-b*b$; higher precision or correctly rounded or correctly truncated arithmetic would be needed to compute *rt2* accurately in all cases. *cs1* and *sn1* are accurate to a few ulps barring over/underflow. Overflow is possible only if *rt1* is within a factor of 5 of overflow. Underflow is harmless if the input data is 0 or exceeds *underflow_threshold* / *macheps*.

?laexc
