Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.

Syntax

```
call slaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
call dlaexc( wantq, n, t, ldt, q, ldq, j1, n1, n2, work, info )
```

Description

This routine swaps adjacent diagonal blocks T_{11} and T_{22} of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

Input Parameters

<i>wantq</i>	LOGICAL. If <i>wantq</i> = .TRUE., accumulate the transformation in the matrix Q ; If <i>wantq</i> = .FALSE., do not accumulate the transformation.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>t, q</i>	REAL for slaexc DOUBLE PRECISION for dlaexc Arrays: <i>t</i> (<i>ldt</i> ,*) contains on entry the upper quasi-triangular matrix T , in Schur canonical form. The second dimension of <i>t</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq</i> ,*) contains on entry, if <i>wantq</i> = .TRUE., the orthogonal matrix Q . If <i>wantq</i> = .FALSE., <i>q</i> is not referenced. The second dimension of <i>q</i> must be at least $\max(1, n)$.
<i>ldt</i>	INTEGER. The first dimension of <i>t</i> ; at least $\max(1, n)$.
<i>ldq</i>	INTEGER. The first dimension of <i>q</i> ;

If `wantq = .FALSE.`, then $ldq \geq 1$.
 If `wantq = .TRUE.`, then $ldq \geq \max(1, n)$.

`j1` INTEGER. The index of the first row of the first block T_{11} .

`n1` INTEGER. The order of the first block T_{11}
 ($n1 = 0, 1$, or 2).

`n2` INTEGER. The order of the second block T_{22}
 ($n2 = 0, 1$, or 2).

`work` REAL for slaexc;
 DOUBLE PRECISION for dlaexc.
 Workspace array, DIMENSION (n).

Output Parameters

`t` On exit, the updated matrix T , again in Schur canonical form.

`q` On exit, if `wantq = .TRUE.`, the updated matrix Q .

`info` INTEGER.
 If `info = 0`, the execution is successful.
 If `info = 1`, the transformed matrix T would be too far from Schur form; the blocks are not swapped and T and Q are unchanged.

?lag2

Computes the eigenvalues of a 2-by-2 generalized eigenvalue problem, with scaling as necessary to avoid over-/underflow.

Syntax

```
call slag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
call dlag2( a, lda, b, ldb, safmin, scale1, scale2, wr1, wr2, wi )
```

Description

This routine computes the eigenvalues of a 2×2 generalized eigenvalue problem $A - w * B$, with scaling as necessary to avoid over-/underflow. The scaling factor, s , results in a modified eigenvalue equation

$$s^*A - w^*B,$$

where s is a non-negative scaling factor chosen so that w , w^*B , and s^*A do not overflow and, if possible, do not underflow, either.

Input Parameters

a, b	REAL for <code>slag2</code> DOUBLE PRECISION for <code>dlag2</code> Arrays: $a(lda, 2)$ contains, on entry, the 2 x 2 matrix A. It is assumed that its 1-norm is less than $1/safmin$. Entries less than $\text{sqrt}(safmin) * \text{norm}(A)$ are subject to being treated as zero. $b(l db, 2)$ contains, on entry, the 2 x 2 upper triangular matrix B. It is assumed that the one-norm of B is less than $1/safmin$. The diagonals should be at least $\text{sqrt}(safmin)$ times the largest element of B (in absolute value); if a diagonal is smaller than that, then $\pm \text{sqrt}(safmin)$ will be used instead of that diagonal.
lda	INTEGER. The first dimension of a ; $lda \geq 2$.
ldb	INTEGER. The first dimension of b ; $ldb \geq 2$.
$safmin$	REAL for <code>slag2</code>; DOUBLE PRECISION for <code>dlag2</code>. The smallest positive number such that $1/safmin$ does not overflow. (This should always be <code>?lamch('S')</code> - it is an argument in order to avoid having to call <code>?lamch</code> frequently.)

Output Parameters

$scale1$	REAL for <code>slag2</code>; DOUBLE PRECISION for <code>dlag2</code>. A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the first eigenvalue. If the eigenvalues are complex, then the eigenvalues are $(wr1 \pm wii)/scale1$ (which may lie outside the exponent range of the machine), $scale1 = scale2$, and $scale1$ will always be positive.

If the eigenvalues are real, then the first (real) eigenvalue is $wr1/scale1$, but this may overflow or underflow, and in fact, $scale1$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

scale2

REAL for *slag2*;

DOUBLE PRECISION for *dlag2*.

A scaling factor used to avoid over-/underflow in the eigenvalue equation which defines the second eigenvalue. If the eigenvalues are complex, then $scale2=scale1$. If the eigenvalues are real, then the second (real) eigenvalue is $wr2/scale2$, but this may overflow or underflow, and in fact, $scale2$ may be zero or less than the underflow threshold if the exact eigenvalue is sufficiently large.

wr1

REAL for *slag2*;

DOUBLE PRECISION for *dlag2*.

If the eigenvalue is real, then $wr1$ is $scale1$ times the eigenvalue closest to the (2,2) element of $A \cdot \text{inv}(B)$. If the eigenvalue is complex, then $wr1=wr2$ is $scale1$ times the real part of the eigenvalues.

wr2

REAL for *slag2*;

DOUBLE PRECISION for *dlag2*.

If the eigenvalue is real, then $wr2$ is $scale2$ times the other eigenvalue. If the eigenvalue is complex, then $wr1=wr2$ is $scale1$ times the real part of the eigenvalues.

wi

REAL for *slag2*;

DOUBLE PRECISION for *dlag2*.

If the eigenvalue is real, then wi is zero. If the eigenvalue is complex, then wi is $scale1$ times the imaginary part of the eigenvalues. wi will always be non-negative.

slags2

Computes 2-by-2 orthogonal matrices U , V , and Q , and applies them to matrices A and B such that the rows of the transformed A and B are parallel.

Syntax

```
call slags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq )
call dlags2( upper, a1, a2, a3, b1, b2, b3, csu, snu, csv, snv, csq, snq )
```

Description

This routine computes 2-by-2 orthogonal matrices U , V and Q , such that if $upper = .TRUE.$, then

$$U^* A Q = U^* \begin{bmatrix} A_1 & A_2 \\ 0 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

and

$$V^* B Q = V^* \begin{bmatrix} B_1 & B_2 \\ 0 & B_3 \end{bmatrix} * Q = \begin{bmatrix} x & 0 \\ x & x \end{bmatrix}$$

or if $upper = .FALSE.$, then

$$U^* A Q = U^* \begin{bmatrix} A_1 & 0 \\ A_2 & A_3 \end{bmatrix} * Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

and

$$V^* B Q = U^* \begin{bmatrix} B_1 & 0 \\ B_2 & B_3 \end{bmatrix} Q = \begin{bmatrix} x & x \\ 0 & x \end{bmatrix}$$

The rows of the transformed A and B are parallel, where

$$U = \begin{bmatrix} csu & snu \\ -snu & csu \end{bmatrix}, V = \begin{bmatrix} csv & snv \\ -snv & csv \end{bmatrix}, Q = \begin{bmatrix} csq & snq \\ -snq & csq \end{bmatrix}$$

Here Z' denotes the transpose of Z .

Input Parameters

<i>upper</i>	LOGICAL. If <i>upper</i> = .TRUE., the input matrices A and B are upper triangular; If <i>upper</i> = .FALSE., the input matrices A and B are lower triangular.
<i>a1, a2, a3</i>	REAL for slags2 DOUBLE PRECISION for dlags2 On entry, <i>a1</i> , <i>a2</i> and <i>a3</i> are elements of the input 2-by-2 upper (lower) triangular matrix A .
<i>b1, b2, b3</i>	REAL for slags2 DOUBLE PRECISION for dlags2 On entry, <i>b1</i> , <i>b2</i> and <i>b3</i> are elements of the input 2-by-2 upper (lower) triangular matrix B .

Output Parameters

<i>csu, snu</i>	REAL for slags2 DOUBLE PRECISION for dlags2 The desired orthogonal matrix U .
<i>csv, snv</i>	REAL for slags2 DOUBLE PRECISION for dlags2 The desired orthogonal matrix V .
<i>csq, snq</i>	REAL for slags2 DOUBLE PRECISION for dlags2

The desired orthogonal matrix Q .

?lagtf

Computes an LU factorization of a matrix $T - \lambda * I$, where T is a general tridiagonal matrix, and λ is a scalar, using partial pivoting with row interchanges.

Syntax

```
call slagtf( n, a, lambda, b, c, tol, d, in, info )
call dlagtf( n, a, lambda, b, c, tol, d, in, info )
```

Description

This routine factorizes the matrix $(T - \lambda * I)$, where T is an n -by- n tridiagonal matrix and λ is a scalar, as

$$T - \lambda * I = P * L * U,$$

where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column. The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling. The parameter λ is included in the routine so that ?lagtf may be used, in conjunction with ?lagts, to obtain eigenvectors of T by inverse iteration.

Input Parameters

n	INTEGER. The order of the matrix T ($n \geq 0$).
a, b, c	REAL for slagtf DOUBLE PRECISION for dlagtf Arrays, dimension $a(n), b(n-1), c(n-1)$: On entry, $a(*)$ must contain the diagonal elements of the matrix T . On entry, $b(*)$ must contain the $(n-1)$ super-diagonal elements of T . On entry, $c(*)$ must contain the $(n-1)$ sub-diagonal elements of T .
tol	REAL for slagtf

DOUBLE PRECISION for `dlagtf`

On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. `tol` should normally be chosen as approximately the largest relative error in the elements of T . For example, if the elements of T are correct to about 4 significant figures, then `tol` should be set to about 5×10^{-4} . If `tol` is supplied as less than `eps`, where `eps` is the relative machine precision, then the value `eps` is used in place of `tol`.

Output Parameters

<i>a</i>	On exit, <i>a</i> is overwritten by the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> of the factorization of <i>T</i> .
<i>b</i>	On exit, <i>b</i> is overwritten by the <i>n</i> -1 super-diagonal elements of the matrix <i>U</i> of the factorization of <i>T</i> .
<i>c</i>	On exit, <i>c</i> is overwritten by the <i>n</i> -1 sub-diagonal elements of the matrix <i>L</i> of the factorization of <i>T</i> .
<i>d</i>	REAL for <code>slagtf</code> DOUBLE PRECISION for <code>dlagtf</code> Array, dimension (<i>n</i> -2). On exit, <i>d</i> is overwritten by the <i>n</i> -2 second super-diagonal elements of the matrix <i>U</i> of the factorization of <i>T</i> .
<i>in</i>	INTEGER. Array, dimension (<i>n</i>). On exit, <i>in</i> contains details of the permutation matrix <i>p</i> . If an interchange occurred at the <i>k</i> -th step of the elimination, then <i>in</i> (<i>k</i>) = 1, otherwise <i>in</i> (<i>k</i>) = 0. The element <i>in</i> (<i>n</i>) returns the smallest positive integer <i>j</i> such that $\text{abs}(u(j,j)) \leq \text{norm}((T - \lambda I)(j)) * \text{tol},$ where $\text{norm}(A(j))$ denotes the sum of the absolute values of the <i>j</i> -th row of the matrix <i>A</i> . If no such <i>j</i> exists then <i>in</i> (<i>n</i>) is returned as zero. If <i>in</i> (<i>n</i>) is returned as positive, then a diagonal element of <i>U</i> is small, indicating that $(T - \lambda I)$ is singular or nearly singular.
<i>info</i>	INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*k*, the *k*-th parameter had an illegal value.

?lagtm

Performs a matrix-matrix product of the form $C = \alpha * A * B + \beta * C$, where A is a tridiagonal matrix, B and C are rectangular matrices, and α and β are scalars, which may be 0, 1, or -1.

Syntax

```
call slagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call dlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call clagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
call zlagtm( trans, n, nrhs, alpha, dl, d, du, x, ldx, beta, b, ldb )
```

Description

This routine performs a matrix-vector product of the form:

$$B := \alpha * A * X + \beta * B$$

where A is a tridiagonal matrix of order n , B and X are n -by- $nrhs$ matrices, and α and β are real scalars, each of which may be 0., 1., or -1.

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $B := \alpha * A * X + \beta * B$ (no transpose); If <i>trans</i> = 'T', then $B := \alpha * A^T * X + \beta * B$ (transpose); If <i>trans</i> = 'C', then $B := \alpha * A^H * X + \beta * B$ (conjugate transpose)
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).

<i>nrhs</i>	INTEGER. The number of right-hand sides, i.e., the number of columns in X and B ($nrhs \geq 0$).
<i>alpha, beta</i>	REAL for <code>slagtm/clagtm</code> DOUBLE PRECISION for <code>dlagtm/zlagtm</code> Specify the scalars <i>alpha</i> and <i>beta</i> respectively. <i>alpha</i> must be 0., 1., or -1.; otherwise, it is assumed to be 0. <i>beta</i> must be 0., 1., or -1.; otherwise, it is assumed to be 1.
<i>dl, d, du</i>	REAL for <code>slagtm</code> DOUBLE PRECISION for <code>dlagtm</code> COMPLEX for <code>clagtm</code> COMPLEX*16 for <code>zlagtm</code> . Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$. The array <i>dl</i> contains the $(n-1)$ sub-diagonal elements of T . The array <i>d</i> contains the n diagonal elements of T . The array <i>du</i> contains the $(n-1)$ super-diagonal elements of T .
<i>x, b</i>	REAL for <code>slagtm</code> DOUBLE PRECISION for <code>dlagtm</code> COMPLEX for <code>clagtm</code> COMPLEX*16 for <code>zlagtm</code> . Arrays: $x(ldx,*)$ contains the n -by- $nrhs$ matrix X . The second dimension of x must be at least $\max(1, nrhs)$. $b(l db,*)$ contains the n -by- $nrhs$ matrix B . The second dimension of b must be at least $\max(1, nrhs)$.
<i>ldx</i>	INTEGER. The leading dimension of the array x ; $ldx \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the matrix expression $B := \alpha A^* X + \beta B$

?lagts

Solves the system of equations $(T - \lambda I)x = y$ or $(T - \lambda I)^T x = y$, where T is a general tridiagonal matrix and λ is a scalar, using the LU factorization computed by ?lagtf.

Syntax

```
call slagts( job, n, a, b, c, d, in, y, tol, info )
call dlagts( job, n, a, b, c, d, in, y, tol, info )
```

Description

This routine may be used to solve for x one of the systems of equations:

$$(T - \lambda I)x = y \quad \text{or} \quad (T - \lambda I)^T x = y,$$

where T is an n -by- n tridiagonal matrix, following the factorization of $(T - \lambda I)$ as

$$T - \lambda I = P * L * U,$$

computed by the routine ?lagtf.

The choice of equation to be solved is controlled by the argument *job*, and in each case there is an option to perturb zero or very small diagonal elements of U , this option being intended for use in applications such as inverse iteration.

Input Parameters

<i>job</i>	INTEGER. Specifies the job to be performed by ?lagts as follows: = 1: The equations $(T - \lambda I)x = y$ are to be solved, but diagonal elements of U are not to be perturbed. = -1: The equations $(T - \lambda I)x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument <i>tol</i> below. = 2: The equations $(T - \lambda I)^T x = y$ are to be solved, but diagonal elements of U are not to be perturbed. = -2: The equations $(T - \lambda I)^T x = y$ are to be solved and, if overflow would otherwise occur, the diagonal elements of U are to be perturbed. See argument <i>tol</i> below.

n INTEGER. The order of the matrix T ($n \geq 0$).

a, b, c, d REAL for `slagts`
DOUBLE PRECISION for `dlagts`
Arrays, dimension $a(n)$, $b(n-1)$, $c(n-1)$, $d(n-2)$:
On entry, $a(*)$ must contain the diagonal elements of U as returned from `?lagtf`.
On entry, $b(*)$ must contain the first super-diagonal elements of U as returned from `?lagtf`.
On entry, $c(*)$ must contain the sub-diagonal elements of L as returned from `?lagtf`.
On entry, $d(*)$ must contain the second super-diagonal elements of U as returned from `?lagtf`.

in INTEGER.
Array, dimension (n) .
On entry, $in(*)$ must contain details of the matrix p as returned from `?lagtf`.

y REAL for `slagts`
DOUBLE PRECISION for `dlagts`
Array, dimension (n) . On entry, the right hand side vector y .

tol REAL for `slagtf`
DOUBLE PRECISION for `dlagtf`.
On entry, with $job < 0$, *tol* should be the minimum perturbation to be made to very small diagonal elements of U . *tol* should normally be chosen as about $eps * \text{norm}(U)$, where eps is the relative machine precision, but if *tol* is supplied as non-positive, then it is reset to $eps * \max(|u(i,j)|)$. If $job > 0$ then *tol* is not referenced.

Output Parameters

y On exit, y is overwritten by the solution vector x .

tol On exit, *tol* is changed as described in *Input Parameters* section above, only if *tol* is non-positive on entry. Otherwise *tol* is unchanged.

info INTEGER.
If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value. If $info = i > 0$, overflow would occur when computing the i th element of the solution vector x . This can only occur when job is supplied as positive and either means that a diagonal element of U is very small, or that the elements of the right-hand side vector y are very large.

?lagv2

Computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A,B) where B is upper triangular.

Syntax

```
call slagv2( a, lda, b, ldb, alphas, alphai, beta, cs1, sn1, csr, snr )
call dlagv2( a, lda, b, ldb, alphas, alphai, beta, cs1, sn1, csr, snr )
```

Description

This routine computes the Generalized Schur factorization of a real 2-by-2 matrix pencil (A,B) where B is upper triangular. The routine computes orthogonal (rotation) matrices given by $cs1$, $sn1$ and csr , snr such that:

- 1) if the pencil (A,B) has two real eigenvalues (include 0/0 or 1/0 types), then

$$\begin{bmatrix} a_{11} & a_{12} \\ 0 & a_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

- 2) if the pencil (A,B) has a pair of complex conjugate eigenvalues, then

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

$$\begin{bmatrix} b_{11} & 0 \\ 0 & b_{22} \end{bmatrix} = \begin{bmatrix} cs1 & sn1 \\ -sn1 & cs1 \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ 0 & b_{22} \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix}$$

where $b_{11} \geq b_{22} > 0$.

Input Parameters

a, b REAL for `slagv2`
DOUBLE PRECISION for `dlagv2`
Arrays:
a(l da,2) contains the 2-by-2 matrix *A*;
b(l db,2) contains the upper triangular 2-by-2 matrix *B*.
lda INTEGER. The leading dimension of the array *a*;
lda ≥ 2.
ldb INTEGER. The leading dimension of the array *b*;
ldb ≥ 2.

Output Parameters

a On exit, *a* is overwritten by the "A-part" of the generalized Schur form.
b On exit, *b* is overwritten by the "B-part" of the generalized Schur form.
alphan, alphai, beta REAL for `slagv2`
DOUBLE PRECISION for `dlagv2`.
Arrays, dimension (2) each.
(*alphan(k) + i*alphai(k)*)/*beta(k)* are the eigenvalues of the pencil (*A,B*), *k*=1,2 and *i* = `sqrt(-1)`.
Note that *beta(k)* may be zero.
cs1, sn1 REAL for `slagv2`

	DOUBLE PRECISION for dlagv2
	The cosine and sine of the left rotation matrix, respectively.
<i>csr, snr</i>	REAL for slagv2
	DOUBLE PRECISION for dlagv2
	The cosine and sine of the right rotation matrix, respectively.

?lahqr

Computes the eigenvalues and Schur factorization of an upper Hessenberg matrix, using the double-shift/single-shift QR algorithm.

Syntax

```
call slahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
info )

call dlahqr( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
info )

call clahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info
)

call zlahqr( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, info
)
```

Description

This routine is an auxiliary routine called by [?hseqr](#) to update the eigenvalues and Schur decomposition already computed by [?hseqr](#), by dealing with the Hessenberg submatrix in rows and columns *ilo* to *ihi*.

Input Parameters

<i>wantt</i>	LOGICAL. If <i>wantt</i> = .TRUE., the full Schur form <i>T</i> is required; If <i>wantt</i> = .FALSE., eigenvalues only are required.
<i>wantz</i>	LOGICAL. If <i>wantz</i> = .TRUE., the matrix of Schur vectors <i>Z</i> is required; If <i>wantz</i> = .FALSE., Schur vectors are not required.

n INTEGER. The order of the matrix H ($n \geq 0$).

ilo, ihi INTEGER.
It is assumed that h is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $h(ilo, ilo-1) = 0$ (unless $ilo = 1$). The routine ?lahqr works primarily with the Hessenberg submatrix in rows and columns ilo to ihi , but applies transformations to all of h if $wantt = .TRUE..$
Constraints:
 $1 \leq ilo \leq \max(1, ihi); ihi \leq n$.

h, z REAL for slahqr
DOUBLE PRECISION for dlahqr
COMPLEX for clahqr
COMPLEX*16 for zlahqr.
Arrays:
 $h(ldh,*)$ contains the upper Hessenberg matrix h .
The second dimension of h must be at least $\max(1, n)$.
 $z(ldz,*)$
If $wantz = .TRUE.$, then, on entry, z must contain the current matrix z of transformations accumulated by ?hseqr.
If $wantz = .FALSE.$, then z is not referenced. The second dimension of z must be at least $\max(1, n)$.

ldh INTEGER. The first dimension of h ; at least $\max(1, n)$.

ldz INTEGER. The first dimension of z ; at least $\max(1, n)$.

iloz, ihiz INTEGER. Specify the rows of z to which transformations must be applied if $wantz = .TRUE..$
 $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$.

Output Parameters

h On exit, if $info = 0$ and $wantt = .TRUE.$, then,

- for slahqr/dlahqr, h is upper quasi-triangular in rows and columns $ilo:ihi$ with any 2-by-2 diagonal blocks in standard form.
- for clahqr/zlahqr, h is upper triangular in rows and columns $ilo:ihi$.

If *info* = 0 and *wantt* = .FALSE., the contents of *h* are unspecified on exit. If *info* is positive, see description of *info* for the output state of *h*.

wr, wi REAL for *slahqr*
 DOUBLE PRECISION for *dlahqr*
 Arrays, DIMENSION at least $\max(1, n)$ each. Used with real flavors only. The real and imaginary parts, respectively, of the computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *wr* and *wi*. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)-th, with *wi*(*i*) > 0 and *wi*(*i*+1) < 0.
 If *wantt* = .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *wr*(*i*) = *h*(*i*,*i*), and, if *h*(*i*:*i*+1, *i*:*i*+1) is a 2-by-2 diagonal block, *wi*(*i*) = $\sqrt{h(i+1,i)*h(i,i+1)}$ and *wi*(*i*+1) = -*wi*(*i*).

w COMPLEX for *clahqr*
 COMPLEX*16 for *zlahqr*.
 Array, DIMENSION at least $\max(1, n)$. Used with complex flavors only. The computed eigenvalues *ilo* to *ihi* are stored in the corresponding elements of *w*.
 If *wantt* = .TRUE., the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in *h*, with *w*(*i*) = *h*(*i*,*i*).

z If *wantz* = .TRUE., then, on exit *z* has been updated; transformations are applied only to the submatrix *z*(*iloz*:*ihiz*, *ilo*:*ihi*).

info INTEGER.
 If *info* = 0, the execution is successful.
 With *info* > 0,

- if *info* = *i*, ?*lahqr* failed to compute all the eigenvalues *ilo* to *ihi* in a total of 30 iterations per eigenvalue; elements *i*+1:*ihi* of *wr* and *wi* (for *slahqr*/*dlahqr*) or *w* (for *clahqr*/*zlahqr*) contain those eigenvalues which have been successfully computed.

- if `wantt` is `.FALSE.`, then on exit the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns `ilo` through `info` of the final output value of `h`.
- if `wantt` is `.TRUE.`, then on exit

(initial value of h)* u = u *(final value of h),
(*)

where u is an orthogonal matrix. The final value of h is upper Hessenberg and triangular in rows and columns `info+1` through `ihi`.

- if `wantz` is `.TRUE.`, then on exit

(final value of z) = (initial value of z)* u ,

where u is an orthogonal matrix in (*) regardless of the value of `wantt`.

?lahrd

Reduces the first `nb` columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .

Syntax

```
call slahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call zlahrd( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Description

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation $Q^* A Q$. The routine returns the matrices V and T which determine Q as a block reflector $I - V^* T^* V$, and also the matrix $Y = A^* V^* T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^*$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an obsolete auxiliary routine. Please use the new routine `zlahr2` instead.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
k	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
nb	INTEGER. The number of columns to be reduced.
a	REAL for <code>slahrd</code> DOUBLE PRECISION for <code>dlahrd</code> COMPLEX for <code>clahrd</code> COMPLEX*16 for <code>zlahrd</code> . Array $a(lda, n-k+1)$ contains the n -by- $(n-k+1)$ general matrix A to be reduced.
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.
ldt	INTEGER. The first dimension of the output array t ; must be at least $\max(1, nb)$.
ldy	INTEGER. The first dimension of the output array y ; must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	On exit, the elements on and above the <i>k</i> -th subdiagonal in the first <i>nb</i> columns are overwritten with the corresponding elements of the reduced matrix; the elements below the <i>k</i> -th subdiagonal, with the array <i>tau</i> , represent the matrix <i>Q</i> as a product of elementary reflectors. The other columns of <i>a</i> are unchanged. See <i>Application Notes</i> below.
<i>tau</i>	REAL for slahrd DOUBLE PRECISION for dlahrd COMPLEX for clahrd COMPLEX*16 for zlahrd. Array, DIMENSION (<i>nb</i>). Contains scalar factors of the elementary reflectors.
<i>t</i> , <i>y</i>	REAL for slahrd DOUBLE PRECISION for dlahrd COMPLEX for clahrd COMPLEX*16 for zlahrd. Arrays, dimension <i>t</i> (<i>ldt</i> , <i>nb</i>), <i>y</i> (<i>ldy</i> , <i>nb</i>). The array <i>t</i> contains upper triangular matrix <i>T</i> . The array <i>y</i> contains the <i>n</i> -by- <i>nb</i> matrix <i>Y</i> .

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and *tau* is stored in *tau*(*i*).

The elements of the vectors *v* together form the (*n-k+1*)-by-*nb* matrix *V* which is needed, with *T* and *Y*, to apply the transformation to the unreduced part of the matrix, using an update of the form:

$$A := (I - V^* T^* V') * (A - Y^* V').$$

The contents of *A* on exit are illustrated by the following example with $n = 7$, $k = 3$ and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

slahr2

Reduces the specified number of first columns of a general rectangular matrix A so that elements below the specified subdiagonal are zero, and returns auxiliary matrices which are needed to apply the transformation to the unreduced part of A .

Syntax

```
call slahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call dlahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call clahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
call zlahr2( n, k, nb, a, lda, tau, t, ldt, y, ldy )
```

Description

The routine reduces the first nb columns of a real/complex general n -by- $(n-k+1)$ matrix A so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q'^*A*Q . The routine returns the matrices V and T which determine Q as a block reflector $I - V*T*V'$, and also the matrix $Y = A*V*T$.

The matrix Q is represented as products of nb elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector.

This is an auxiliary routine called by `?gehrd`.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
k	INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero ($k < n$).
nb	INTEGER. The number of columns to be reduced.
a	REAL for <code>slahr2</code> DOUBLE PRECISION for <code>dlahr2</code> COMPLEX for <code>clahr2</code> COMPLEX*16 for <code>zlahr2</code> . Array, DIMENSION ($lda, n-k+1$) contains the n -by- $(n-k+1)$ general matrix A to be reduced.
lda	INTEGER. The first dimension of the array a ; $lda \geq \max(1, n)$.
ldt	INTEGER. The first dimension of the output array t ; $ldt \geq nb$.
ldy	INTEGER. The first dimension of the output array y ; $ldy \geq n$.

Output Parameters

a	On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced matrix; the elements below the k -th subdiagonal, with the array τ , represent the matrix Q as a product of elementary reflectors. The other columns of a are unchanged. See <i>Application Notes</i> below.

tau REAL for slahr2
DOUBLE PRECISION for dlahr2
COMPLEX for clahr2
COMPLEX*16 for zlahr2.
Array, DIMENSION (*nb*).
Contains scalar factors of the elementary reflectors.

t, y REAL for slahr2
DOUBLE PRECISION for dlahr2
COMPLEX for clahr2
COMPLEX*16 for zlahr2.
Arrays, dimension $t(ldt, nb)$, $y(ldy, nb)$.
The array *t* contains upper triangular matrix *T*.
The array *y* contains the *n*-by-*nb* matrix *Y*.

Application Notes

For the elementary reflector $H(i)$,

$v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $a(i+k+1:n, i)$ and *tau* is stored in *tau*(*i*).

The elements of the vectors *v* together form the $(n-k+1)$ -by-*nb* matrix *V* which is needed, with *T* and *Y*, to apply the transformation to the unreduced part of the matrix, using an update of the form:

$$A := (I - V * T * V') * (A - Y * V').$$

The contents of *A* on exit are illustrated by the following example with $n = 7$, $k = 3$ and *nb* = 2:

$$\begin{bmatrix} a & a & a & a & a \\ a & a & a & a & a \\ a & a & a & a & a \\ h & h & a & a & a \\ v_1 & h & a & a & a \\ v_1 & v_2 & a & a & a \\ v_1 & v_2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

?laic1

Applies one step of incremental condition estimation.

Syntax

```
call slaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call dlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
call claic1( job, j, x, sest, w, gamma, sestpr, s, c )
call zlaic1( job, j, x, sest, w, gamma, sestpr, s, c )
```

Description

The routine ?laic1 applies one step of incremental condition estimation in its simplest version.

Let x , $\|x\|_2 = 1$ (where $\|a\|_2$ denotes the 2-norm of a), be an approximate singular vector of an j -by- j lower triangular matrix L , such that

$$\|L^*x\|_2 = \text{sest}$$

Then ?laic1 computes sestpr , s , c such that the vector

$$\text{xhat} = \begin{bmatrix} s^*x \\ c \end{bmatrix}$$

is an approximate singular vector of

$$\text{Lhat} = \begin{bmatrix} L & 0 \\ w^t & \text{gamma} \end{bmatrix}$$

in the sense that

$||Lhat*xhat||_2 = sestpr.$

Depending on *job*, an estimate for the largest or smallest singular value is computed.

Note that $[s \ c]^T$ and $sestpr^2$ is an eigenpair of the system (for slaic1/claic)

$$\text{diag}(sest*sest, 0) + [\alpha \ \gamma] * \begin{bmatrix} \alpha \\ \gamma \end{bmatrix}$$

where $\alpha = x'*w$;

or of the system (for claic1/zlaic)

$$\text{diag}(sest*sest, 0) + [\alpha \ \gamma] * \begin{bmatrix} \text{conjg}(\alpha) \\ \text{conjg}(\gamma) \end{bmatrix}$$

where $\alpha = \text{conjg}(x)^T * w$.

Input Parameters

<i>job</i>	INTEGER. If <i>job</i> =1, an estimate for the largest singular value is computed; If <i>job</i> =2, an estimate for the smallest singular value is computed;
<i>j</i>	INTEGER. Length of <i>x</i> and <i>w</i> .
<i>x, w</i>	REAL for slaic1 DOUBLE PRECISION for dlaic1 COMPLEX for claic1 COMPLEX*16 for zlaic1. Arrays, dimension (<i>j</i>) each. Contain vectors <i>x</i> and <i>w</i> , respectively.
<i>sest</i>	REAL for slaic1/claic1; DOUBLE PRECISION for dlaic1/zlaic1. Estimated singular value of <i>j</i> -by- <i>j</i> matrix <i>L</i> .
<i>gamma</i>	REAL for slaic1

DOUBLE PRECISION for `dlaic1`
 COMPLEX for `claic1`
 COMPLEX*16 for `zlaic1`.
 The diagonal element *gamma*.

Output Parameters

sestpr REAL for `slaic1/claic1`;
 DOUBLE PRECISION for `dlaic1/zlaic1`.
 Estimated singular value of $(j+1)$ -by- $(j+1)$ matrix *Lhat*.

s, c REAL for `slaic1`
 DOUBLE PRECISION for `dlaic1`
 COMPLEX for `claic1`
 COMPLEX*16 for `zlaic1`.
 Sine and cosine needed in forming *xhat*.

?laln2

Solves a 1-by-1 or 2-by-2 linear system of equations of the specified form.

Syntax

```
call slaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx,
scale, xnorm, info )
```

```
call dlaln2( ltrans, na, nw, smin, ca, a, lda, d1, d2, b, ldb, wr, wi, x, ldx,
scale, xnorm, info )
```

Description

The routine solves a system of the form

$$(ca*A - w*D)*X = s*B, \text{ or } (ca*A' - w*D)*X = s*B$$

with possible scaling (*s*) and perturbation of *A* (*A'* means *A*-transpose.)

A is an *na*-by-*na* real matrix, *ca* is a real scalar, *D* is an *na*-by-*na* real diagonal matrix, *w* is a real or complex value, and *X* and *B* are *na*-by-1 matrices: real if *w* is real, complex if *w* is complex. The parameter *na* may be 1 or 2.

If *w* is complex, *X* and *B* are represented as *na*-by-2 matrices, the first column of each being the real part and the second being the imaginary part.

The routine computes the scaling factor s (≤ 1) so chosen that x can be computed without overflow. x is further scaled if necessary to assure that $\text{norm}(ca*A - w*D) * \text{norm}(X)$ is less than overflow.

If both singular values of $(ca*A - w*D)$ are less than $smin$, $smin*I$ (where I stands for identity) will be used instead of $(ca*A - w*D)$. If only one singular value is less than $smin$, one element of $(ca*A - w*D)$ will be perturbed enough to make the smallest singular value roughly $smin$.

If both singular values are at least $smin$, $(ca*A - w*D)$ will not be perturbed. In any case, the perturbation will be at most some small multiple of $\max(smin, ulp * \text{norm}(ca*A - w*D))$.

The singular values are computed by infinity-norm approximations, and thus will only be correct to a factor of 2 or so.

NOTE. All input quantities are assumed to be smaller than overflow by a reasonable factor (see *bignum*).

Input Parameters

<i>trans</i>	LOGICAL. If <i>trans</i> = .TRUE., <i>A</i> - transpose will be used. If <i>trans</i> = .FALSE., <i>A</i> will be used (not transposed.)
<i>na</i>	INTEGER. The size of the matrix <i>A</i> , possible values 1 or 2.
<i>nw</i>	INTEGER. This parameter must be 1 if <i>w</i> is real, and 2 if <i>w</i> is complex. Possible values 1 or 2.
<i>smin</i>	REAL for slaln2 DOUBLE PRECISION for dlaln2. The desired lower bound on the singular values of <i>A</i> . This should be a safe distance away from underflow or overflow, for example, between $(\text{underflow}/\text{machine\_precision})$ and $(\text{machine\_precision} * \text{overflow})$. (See <i>bignum</i> and <i>ulp</i>).
<i>ca</i>	REAL for slaln2 DOUBLE PRECISION for dlaln2. The coefficient by which <i>A</i> is multiplied.
<i>a</i>	REAL for slaln2 DOUBLE PRECISION for dlaln2.

Array, DIMENSION (lda, na).
The na -by- na matrix A .

lda INTEGER. The leading dimension of a . Must be at least na .

$d1, d2$ REAL for slaln2
DOUBLE PRECISION for dlaln2.
The (1,1) and (2,2) elements in the diagonal matrix D , respectively. $d2$ is not used if $nw = 1$.

b REAL for slaln2
DOUBLE PRECISION for dlaln2.
Array, DIMENSION (ldb, nw). The na -by- nw matrix B (right-hand side). If $nw = 2$ (w is complex), column 1 contains the real part of B and column 2 contains the imaginary part.

ldb INTEGER. The leading dimension of b . Must be at least na .

wr, wi REAL for slaln2
DOUBLE PRECISION for dlaln2.
The real and imaginary part of the scalar w , respectively. wi is not used if $nw = 1$.

ldx INTEGER. The leading dimension of the output array x . Must be at least na .

Output Parameters

x REAL for slaln2
DOUBLE PRECISION for dlaln2.
Array, DIMENSION (ldx, nw). The na -by- nw matrix X (unknowns), as computed by the routine. If $nw = 2$ (w is complex), on exit, column 1 will contain the real part of x and column 2 will contain the imaginary part.

$scale$ REAL for slaln2
DOUBLE PRECISION for dlaln2.
The scale factor that B must be multiplied by to insure that overflow does not occur when computing X . Thus $(ca * A - w * D) X$ will be $scale * B$, not B (ignoring perturbations of A .) It will be at most 1.

$xnorm$ REAL for slaln2
DOUBLE PRECISION for dlaln2.

info

The infinity-norm of X , when X is regarded as an na -by- nw real matrix.

INTEGER.

An error flag. It will be zero if no error occurs, a negative number if an argument is in error, or a positive number if $(ca*A - w*D)$ had to be perturbed. The possible values are:

If $info = 0$: no error occurred, and $(ca*A - w*D)$ did not have to be perturbed.

If $info = 1$: $(ca*A - w*D)$ had to be perturbed to make its smallest (or only) singular value greater than $smin$.

NOTE. For higher speed, this routine does not check the inputs for errors.

?lals0

Applies back multiplying factors in solving the least squares problem using divide and conquer SVD approach. Used by ?gelsd.

Syntax

```
call slals0 ( icalpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
             givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )
call dlals0 ( icalpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
             givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, info )
call clals0( icalpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
             givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )
call zlals0( icalpq, nl, nr, sqre, nrhs, b, ldb, bx, ldbx, perm, givptr,
             givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, rwork, info )
```

Description

The routine applies back the multiplying factors of either the left or right singular vector matrix of a diagonal matrix appended by a row to the right hand side matrix B in solving the least squares problem using the divide-and-conquer SVD approach.

For the left singular vector matrix, three types of orthogonal matrices are involved:

(1L) Givens rotations: the number of such rotations is *givptr*; the pairs of columns/rows they were applied to are stored in *givcol*; and the *c*- and *s*-values of these rotations are stored in *givnum*.

(2L) Permutation. The (*nl*+1)-st row of *B* is to be moved to the first row, and for *j*=2:*n*, *perm*(*j*)-th row of *B* is to be moved to the *j*-th row.

(3L) The left singular vector matrix of the remaining matrix.

For the right singular vector matrix, four types of orthogonal matrices are involved:

(1R) The right singular vector matrix of the remaining matrix.

(2R) If *sqre* = 1, one extra Givens rotation to generate the right null space.

(3R) The inverse transformation of (2L).

(4R) The inverse transformation of (1L).

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: If <i>icompg</i> = 0: Left singular vector matrix. If <i>icompg</i> = 1: Right singular vector matrix.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER. If <i>sqre</i> = 0: the lower block is an <i>nr</i> -by- <i>nr</i> square matrix. If <i>sqre</i> = 1: the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.
<i>nrhs</i>	INTEGER. The number of columns of <i>B</i> and <i>bx</i> . Must be at least 1.
<i>b</i>	REAL for slals0 DOUBLE PRECISION for dlals0 COMPLEX for clals0 COMPLEX*16 for zlals0. Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>).

	Contains the right hand sides of the least squares problem in rows 1 through <i>m</i> .
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> . Must be at least $\max(1, \max(m, n))$.
<i>bx</i>	REAL for slals0 DOUBLE PRECISION for dlals0 COMPLEX for clals0 COMPLEX*16 for zlals0. Workspace array, DIMENSION (<i>ldbx</i> , <i>nrhs</i>).
<i>ldbx</i>	INTEGER. The leading dimension of <i>bx</i> .
<i>perm</i>	INTEGER. Array, DIMENSION (<i>n</i>). The permutations (from deflation and sorting) applied to the two blocks.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i> , 2). Each pair of numbers indicates a pair of rows/columns involved in a Givens rotation.
<i>ldgcol</i>	INTEGER. The leading dimension of <i>givcol</i> , must be at least <i>n</i> .
<i>givnum</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). Each number indicates the <i>c</i> or <i>s</i> value used in the corresponding Givens rotation.
<i>ldgnum</i>	INTEGER. The leading dimension of arrays <i>difr</i> , <i>poles</i> and <i>givnum</i> , must be at least <i>k</i> .
<i>poles</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (<i>ldgnum</i> , 2). On entry, <i>poles</i> (1: <i>k</i> , 1) contains the new singular values obtained from solving the secular equation, and <i>poles</i> (1: <i>k</i> , 2) is an array containing the poles in the secular equation.
<i>difl</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0

	Array, DIMENSION (k). On entry, $difl(i)$ is the distance between i -th updated (undeflated) singular value and the i -th (undeflated) old singular value.
<i>difr</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION ($ldgnum, 2$). On entry, $difr(i, 1)$ contains the distances between i -th updated (undeflated) singular value and the $i+1$ -th (undeflated) old singular value. And $difr(i, 2)$ is the normalizing factor for the i -th right singular vector.
<i>z</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Array, DIMENSION (k). Contains the components of the deflation-adjusted updating row vector.
<i>K</i>	INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.
<i>c</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Contains garbage if $sqr = 0$ and the c value of a Givens rotation related to the right null space if $sqr = 1$.
<i>s</i>	REAL for slals0/clals0 DOUBLE PRECISION for dlals0/zlals0 Contains garbage if $sqr = 0$ and the s value of a Givens rotation related to the right null space if $sqr = 1$.
<i>work</i>	REAL for slals0 DOUBLE PRECISION for dlals0 Workspace array, DIMENSION (k). Used with real flavors only.
<i>rwork</i>	REAL for clals0 DOUBLE PRECISION for zlals0 Workspace array, DIMENSION ($k*(1+nrhs) + 2*nrhs$). Used with complex flavors only.

Output Parameters

<i>b</i>	On exit, contains the solution x in rows 1 through n .

info INTEGER.
 If *info* = 0: successful exit.
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.

?lalsa

Computes the SVD of the coefficient matrix in compact form. Used by ?gelsd.

Syntax

```
call slalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info
)

call dlalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info
)

call clalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork,
info )

call zlalsa( icalmpq, smlsiz, n, nrhs, b, ldb, bx, ldbx, u, ldu, vt, k, difl,
difr, z, poles, givptr, givcol, ldgcol, perm, givnum, c, s, rwork, iwork,
info )
```

Description

The routine is an intermediate step in solving the least squares problem by computing the SVD of the coefficient matrix in compact form. The singular vectors are computed as products of simple orthogonal matrices.

If *icalmpq* = 0, ?lalsa applies the inverse of the left singular vector matrix of an upper bidiagonal matrix to the right hand side; and if *icalmpq* = 1, the routine applies the right singular vector matrix to the right hand side. The singular vector matrices were generated in the compact form by ?lalsa.

Input Parameters

icalmpq INTEGER. Specifies whether the left or the right singular vector matrix is involved. If *icalmpq* = 0: left singular vector matrix is used

	If <i>icompg</i> = 1: right singular vector matrix is used.
<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The row and column dimensions of the upper bidiagonal matrix.
<i>nrhs</i>	INTEGER. The number of columns of <i>b</i> and <i>bx</i> . Must be at least 1.
<i>b</i>	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa COMPLEX*16 for zlalsa Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). Contains the right hand sides of the least squares problem in rows 1 through <i>m</i> .
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, \max(m, n))$.
<i>ldb_x</i>	INTEGER. The leading dimension of the output array <i>bx</i> .
<i>u</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i>). On entry, <i>u</i> contains the left singular vector matrices of all subproblems at the bottom level.
<i>ldu</i>	INTEGER, <i>ldu</i> ≥ <i>n</i> . The leading dimension of arrays <i>u</i> , <i>vt</i> , <i>difl</i> , <i>difr</i> , <i>poles</i> , <i>givnum</i> , and <i>z</i> .
<i>vt</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>smlsiz</i> + 1). On entry, contains the right singular vector matrices of all subproblems at the bottom level.
<i>k</i>	INTEGER array, DIMENSION (<i>n</i>).
<i>difl</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i> , <i>nlvl</i>), where $nlvl = \text{int}(\log_2(n / (smlsiz + 1))) + 1$.
<i>difr</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa

	Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>). On entry, <i>difl</i>(*, <i>i</i>) and <i>difr</i>(*, 2<i>i</i> -1) record distances between singular values on the <i>i</i>-th level and singular values on the (<i>i</i> -1)-th level, and <i>difr</i>(*, 2<i>i</i>) record the normalizing factors of the right singular vectors matrices of subproblems on <i>i</i>-th level.
<i>z</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i>, <i>nlvl</i>). On entry, <i>z</i>(1, <i>i</i>) contains the components of the deflation- adjusted updating the row vector for subproblems on the <i>i</i>-th level.
<i>poles</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>). On entry, <i>poles</i>(*, 2<i>i</i>-1: 2<i>i</i>) contains the new and old singular values involved in the secular equations on the <i>i</i>-th level.
<i>givptr</i>	INTEGER. Array, DIMENSION (<i>n</i>). On entry, <i>givptr</i>(<i>i</i>) records the number of Givens rotations performed on the <i>i</i>-th problem on the computation tree.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i>, 2*<i>nlvl</i>). On entry, for each <i>i</i>, <i>givcol</i>(*, 2<i>i</i>-1: 2<i>i</i>) records the locations of Givens rotations performed on the <i>i</i>-th level on the computation tree.
<i>ldgcol</i>	INTEGER, <i>ldgcol</i> ≥ <i>n</i>. The leading dimension of arrays <i>givcol</i> and <i>perm</i>.
<i>perm</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i>, <i>nlvl</i>). On entry, <i>perm</i>(*, <i>i</i>) records permutations done on the <i>i</i>-th level of the computation tree.
<i>givnum</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>). On entry, <i>givnum</i>(*, 2<i>i</i>-1 : 2<i>i</i>) records the <i>c</i> and <i>s</i> values of Givens rotations performed on the <i>i</i>-th level on the computation tree.
<i>c</i>	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa

	Array, DIMENSION (n). On entry, if the i -th subproblem is not square, $c(i)$ contains the c value of a Givens rotation related to the right null space of the i -th subproblem.
s	REAL for slalsa/clalsa DOUBLE PRECISION for dlalsa/zlalsa Array, DIMENSION (n). On entry, if the i -th subproblem is not square, $s(i)$ contains the s -value of a Givens rotation related to the right null space of the i -th subproblem.
$work$	REAL for slalsa DOUBLE PRECISION for dlalsa Workspace array, DIMENSION at least (n). Used with real flavors only.
$rwork$	REAL for clalsa DOUBLE PRECISION for zlalsa Workspace array, DIMENSION at least $\max(n, (smlsz+1)*nrhs*3)$. Used with complex flavors only.
$iwork$	INTEGER. Workspace array, DIMENSION at least ($3n$).

Output Parameters

b	On exit, contains the solution x in rows 1 through n .
bx	REAL for slalsa DOUBLE PRECISION for dlalsa COMPLEX for clalsa COMPLEX*16 for zlalsa Array, DIMENSION ($ldbx, nrhs$). On exit, the result of applying the left or right singular vector matrix to b .
$info$	INTEGER. If $info = 0$: successful exit If $info = -i < 0$, the i -th argument had an illegal value.

zlalsd

Uses the singular value decomposition of A to solve the least squares problem.

Syntax

```
call slalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork,
info )

call dlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, iwork,
info )

call clalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork,
iwork, info )

call zlalsd( uplo, smlsiz, n, nrhs, d, e, b, ldb, rcond, rank, work, rwork,
iwork, info )
```

Description

The routine uses the singular value decomposition of A to solve the least squares problem of finding x to minimize the Euclidean norm of each column of A^*X-B , where A is n -by- n upper bidiagonal, and X and B are n -by- $nrhs$. The solution X overwrites B .

The singular values of A smaller than $rcond$ times the largest singular value are treated as zero in solving the least squares problem; in this case a minimum norm solution is returned. The actual singular values are returned in d in ascending order.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.

It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Input Parameters

<code>uplo</code>	CHARACTER*1. If <code>uplo = 'U'</code> , d and e define an upper bidiagonal matrix. If <code>uplo = 'L'</code> , d and e define a lower bidiagonal matrix.
<code>smlsiz</code>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<code>n</code>	INTEGER. The dimension of the bidiagonal matrix.

	$n \geq 0$.
<i>nrhs</i>	INTEGER. The number of columns of <i>B</i> . Must be at least 1.
<i>d</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd Array, DIMENSION (<i>n</i> -1). Contains the super-diagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>b</i>	REAL for slalsd DOUBLE PRECISION for dlalsd COMPLEX for clalsd COMPLEX*16 for zlalsd Array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). On input, <i>b</i> contains the right hand sides of the least squares problem. On output, <i>b</i> contains the solution X.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> in the calling subprogram. Must be at least $\max(1, n)$.
<i>rcond</i>	REAL for slalsd/clalsd DOUBLE PRECISION for dlalsd/zlalsd The singular values of <i>A</i> less than or equal to <i>rcond</i> times the largest singular value are treated as zero in solving the least squares problem. If <i>rcond</i> is negative, machine precision is used instead. For example, for the least squares problem $\text{diag}(S) * X = B$, where $\text{diag}(S)$ is a diagonal matrix of singular values, the solution is $X(i) = B(i) / S(i)$ if $S(i)$ is greater than $rcond * \max(S)$, and $X(i) = 0$ if $S(i)$ is less than or equal to $rcond * \max(S)$.
<i>rank</i>	INTEGER. The number of singular values of <i>A</i> greater than <i>rcond</i> times the largest singular value.
<i>work</i>	REAL for slalsd DOUBLE PRECISION for dlalsd COMPLEX for clalsd COMPLEX*16 for zlalsd Workspace array.

work DIMENSION for real flavors at least
 $(9n+2n*smlsiz+8n*nlvl+n*nrhs+(smlsiz+1)^2),$
 where
 $nlvl = \max(0, \text{int}(\log_2(n/(smlsiz+1))) + 1).$
 DIMENSION for complex flavors is $(n*nrhs).$

rwork REAL for clalsd
 DOUBLE PRECISION for zlalsd
 Workspace array, used with complex flavors only.
 DIMENSION at least $(9n + 2n*smlsiz + 8n*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2),$
 where
 $nlvl = \max(0, \text{int}(\log_2(\min(m,n)/(smlsiz+1))) + 1).$

iwork INTEGER.
 Workspace array of DIMENSION $(3n*nlvl + 11n).$

Output Parameters

d On exit, if *info* = 0, *d* contains singular values of the bidiagonal matrix.

e On exit, destroyed.

b On exit, *b* contains the solution *x*.

info INTEGER.
 If *info* = 0: successful exit.
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.
 If *info* > 0: The algorithm failed to compute a singular value while working on the submatrix lying in rows and columns *info*/(*n*+1) through mod(*info*, *n*+1).

zlamrg

Creates a permutation list to merge the entries of two independently sorted sets into a single set sorted in ascending order.

Syntax

```
call slamrg( n1, n2, a, strd1, strd2, index )
call dlamrg( n1, n2, a, strd1, strd2, index )
```

Description

The routine creates a permutation list which will merge the elements of *a* (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

Input Parameters

<i>n1, n2</i>	INTEGER. These arguments contain the respective lengths of the two sorted lists to be merged.
<i>a</i>	REAL for slamrg DOUBLE PRECISION for dlamrg. Array, DIMENSION (<i>n1+n2</i>). The first <i>n1</i> elements of <i>a</i> contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final <i>n2</i> elements.
<i>strd1, strd2</i>	INTEGER. These are the strides to be taken through the array <i>a</i> . Allowable strides are 1 and -1. They indicate whether a subset of <i>a</i> is sorted in ascending (<i>strdx</i> = 1) or descending (<i>strdx</i> = -1) order.

Output Parameters

<i>index</i>	INTEGER. Array, DIMENSION (<i>n1+n2</i>). On exit, this array will contain a permutation such that if $b(i) = a(index(i))$ for $i=1, n1+n2$, then <i>b</i> will be sorted in ascending order.

?laneg

Computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal

$$T\text{-}\sigma I = L^*D^*L^T.$$

Syntax

```
value = slaneg( n, d, lld, sigma, pivmin, r )
```

```
value = dlaneg( n, d, lld, sigma, pivmin, r )
```

Description

The routine computes the Sturm count, the number of negative pivots encountered while factoring tridiagonal $T\text{-}\sigma I = L^*D^*L^T$. This implementation works directly on the factors without forming the tridiagonal matrix T . The Sturm count is also the number of eigenvalues of T less than σ . This routine is called from ?larb. The current routine does not use the *pivmin* parameter but rather requires IEEE-754 propagation of infinities and NaNs (NaN stands for 'Not A Number'). This routine also has no input range restrictions but does require default exception handling such that $x/0$ produces Inf when x is non-zero, and Inf/Inf produces NaN. (For more information see [Marques06]).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix.
<i>d</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the matrix <i>D</i> .
<i>lld</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Array, DIMENSION (<i>n</i> -1). Contains (<i>n</i> -1) elements $L(i)^*L(i)^*D(i)$.
<i>sigma</i>	REAL for slaneg DOUBLE PRECISION for dlaneg Shift amount in $T\text{-}\sigma I = L^*D^*L^*T$.
<i>pivmin</i>	REAL for slaneg DOUBLE PRECISION for dlaneg

The minimum pivot in the Sturm sequence. May be used when zero pivots are encountered on non-IEEE-754 architectures.

r INTEGER.
The twist index for the twisted factorization that is used for the negcount.

Output Parameters

value INTEGER. The number of negative pivots encountered while factoring.

?langb

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of general band matrix.

Syntax

val = slangb(*norm*, *n*, *kl*, *ku*, *ab*, *ldab*, *work*)

val = dlangb(*norm*, *n*, *kl*, *ku*, *ab*, *ldab*, *work*)

val = clangb(*norm*, *n*, *kl*, *ku*, *ab*, *ldab*, *work*)

val = zlangb(*norm*, *n*, *kl*, *ku*, *ab*, *ldab*, *work*)

Description

The function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n band matrix A , with kl sub-diagonals and ku super-diagonals.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),

= 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),
 = 'F', 'f', 'E' or 'e': *val* = normF(*A*), Frobenius norm of the matrix *A* (square root of sum of squares).

n INTEGER. The order of the matrix *A*. $n \geq 0$. When $n = 0$, ?langb is set to zero.

kl INTEGER. The number of sub-diagonals of the matrix *A*. $kl \geq 0$.

ku INTEGER. The number of super-diagonals of the matrix *A*. $ku \geq 0$.

ab REAL for slangb
 DOUBLE PRECISION for dlangb
 COMPLEX for clangb
 COMPLEX*16 for zlangb
 Array, DIMENSION (*ldab*,*n*).
 The band matrix *A*, stored in rows 1 to $kl+ku+1$. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows:
 $ab(ku+1+i-j, j) = a(i, j)$
 for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

ldab INTEGER. The leading dimension of the array *ab*.
 $ldab \geq kl+ku+1$.

work REAL for slangb/clangb
 DOUBLE PRECISION for dlangb/zlangb
 Workspace array, DIMENSION ($\max(1, lwork)$), where
 $lwork \geq n$ when *norm* = 'I'; otherwise, *work* is not referenced.

Output Parameters

val REAL for slangb/clangb
 DOUBLE PRECISION for dlangb/zlangb
 Value returned by the function.

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

```
val = slange( norm, m, n, a, lda, work )
val = dlange( norm, m, n, a, lda, work )
val = clange( norm, m, n, a, lda, work )
val = zlange( norm, m, n, a, lda, work )
```

Description

The function ?lange returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i> . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> . $m \geq 0$. When $m = 0$, ?lange is set to zero.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> . $n \geq 0$. When $n = 0$, ?lange is set to zero.
<i>a</i>	REAL for slange DOUBLE PRECISION for dlange COMPLEX for clange COMPLEX*16 for zlange

	Array, DIMENSION (<i>lda</i> , <i>n</i>).
	The <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . <i>lda</i> ≥ max(<i>m</i> ,1).
<i>work</i>	REAL for <i>srange</i> and <i>clrange</i> . DOUBLE PRECISION for <i>drange</i> and <i>zrange</i> . Workspace array, DIMENSION max(1, <i>lwork</i>), where <i>lwork</i> ≥ <i>m</i> when <i>norm</i> = 'I'; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for <i>srange</i> / <i>clrange</i> DOUBLE PRECISION for <i>drange</i> / <i>zrange</i> Value returned by the function.

?langt

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general tridiagonal matrix.

Syntax

```
val = slangt( norm, n, dl, d, du )
val = dlangt( norm, n, dl, d, du )
val = clangt( norm, n, dl, d, du )
val = zlangt( norm, n, dl, d, du )
```

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex tridiagonal matrix *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine:

= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

n
 INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, **?langt** is set to zero.

dl, d, du
 REAL for slangt
 DOUBLE PRECISION for dlangt
 COMPLEX for clangt
 COMPLEX*16 for zlangt
Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$.
 The array dl contains the $(n-1)$ sub-diagonal elements of A .
 The array d contains the diagonal elements of A .
 The array du contains the $(n-1)$ super-diagonal elements of A .

Output Parameters

val
 REAL for slangt/clangt
 DOUBLE PRECISION for dlangt/zlangt
 Value returned by the function.

?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of an upper Hessenberg matrix.

Syntax

```
val = slanh( norm, n, a, lda, work )
val = dlanhs( norm, n, a, lda, work )
val = clanh( norm, n, a, lda, work )
val = zlanhs( norm, n, a, lda, work )
```

Description

The function `?lanhs` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hessenberg matrix A .

The value `val` returned by the function is:

```
val = max(abs(Aij)), if norm = 'M' or 'm'
= norm1(A), if norm = '1' or 'O' or 'o'
= normI(A), if norm = 'I' or 'i'
= normF(A), if norm = 'F', 'f', 'E' or 'e'
```

where `norm1` denotes the 1-norm of a matrix (maximum column sum), `normI` denotes the infinity norm of a matrix (maximum row sum) and `normF` denotes the Frobenius norm of a matrix (square root of sum of squares). Note that `max(abs(Aij))` is not a consistent matrix norm.

Input Parameters

<code>norm</code>	CHARACTER*1. Specifies the value to be returned by the routine as described above.
<code>n</code>	INTEGER. The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?lanhs</code> is set to zero.
<code>a</code>	REAL for <code>slanh</code> DOUBLE PRECISION for <code>dlanhs</code> COMPLEX for <code>clanh</code>

COMPLEX*16 for zlanhs
 Array, DIMENSION (lda, n). The n -by- n upper Hessenberg matrix A ; the part of A below the first sub-diagonal is not referenced.

lda INTEGER. The leading dimension of the array a .
 $lda \geq \max(n, 1)$.

$work$ REAL for slanhb and clanhb.
 DOUBLE PRECISION for dlange and zlange.
 Workspace array, DIMENSION ($\max(1, lwork)$), where
 $lwork \geq n$ when $norm = 'I'$; otherwise, $work$ is not referenced.

Output Parameters

val REAL for slanhb/clanhb
 DOUBLE PRECISION for dlanhb/zlanhb
 Value returned by the function.

?lansb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric band matrix.

Syntax

```
val = slansb( norm, uplo, n, k, ab, ldab, work )
val = dlansb( norm, uplo, n, k, ab, ldab, work )
val = clansb( norm, uplo, n, k, ab, ldab, work )
val = zlansb( norm, uplo, n, k, ab, ldab, work )
```

Description

The function ?lansb returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n real/complex symmetric band matrix A , with k super-diagonals.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix <i>A</i> is supplied. If <i>uplo</i> = 'U': upper triangular part is supplied; If <i>uplo</i> = 'L': lower triangular part is supplied.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>. $n \geq 0$. When $n = 0$, ?lansb is set to zero.
<i>k</i>	INTEGER. The number of super-diagonals or sub-diagonals of the band matrix <i>A</i>. $k \geq 0$.
<i>ab</i>	REAL for slansb DOUBLE PRECISION for dlansb COMPLEX for clansb COMPLEX*16 for zlansb Array, DIMENSION (<i>ldab</i>,<i>n</i>). The upper or lower triangle of the symmetric band matrix <i>A</i>, stored in the first <i>k</i>+1 rows of <i>ab</i>. The <i>j</i>-th column of <i>A</i> is stored in the <i>j</i>-th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(k+1+i-j, j) = a(i, j)$ for $\max(1, j-k) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq k+1$.

work REAL for slansb and clansb.
 DOUBLE PRECISION for dlansb and zlansb.
 Workspace array, DIMENSION (max(1, *lwork*)), where
lwork ≥ *n* when *norm* = 'I' or '1' or 'O'; otherwise,
work is not referenced.

Output Parameters

val REAL for slansb/clansb
 DOUBLE PRECISION for dlansb/zlansb
 Value returned by the function.

?lanhb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a Hermitian band matrix.

Syntax

```
val = clanhb( norm, uplo, n, k, ab, ldab, work )
val = zlanhb( norm, uplo, n, k, ab, ldab, work )
```

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an *n*-by-*n* Hermitian band matrix *A*, with *k* super-diagonals.

Input Parameters

norm CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': *val* = max(abs(*A*_{*ij*})), largest absolute value of the matrix *A*.
 = '1' or 'O' or 'o': *val* = norm1(*A*), 1-norm of the matrix *A* (maximum column sum),
 = 'I' or 'i': *val* = normI(*A*), infinity norm of the matrix *A* (maximum row sum),

	= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix A is supplied. If <i>uplo</i> = 'U': upper triangular part is supplied; If <i>uplo</i> = 'L': lower triangular part is supplied.
<i>n</i>	INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <i>lanhb</i> is set to zero.
<i>k</i>	INTEGER. The number of super-diagonals or sub-diagonals of the band matrix A. $k \geq 0$.
<i>ab</i>	COMPLEX for <i>clanhb</i>. COMPLEX*16 for <i>zlanhb</i>. Array, DIMENSION (<i>ldaB</i>,<i>n</i>). The upper or lower triangle of the Hermitian band matrix A, stored in the first $k+1$ rows of <i>ab</i>. The j-th column of A is stored in the j-th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(k+1+i-j, j) = a(i, j)$ for $\max(1, j-k) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq k+1$.
<i>work</i>	REAL for <i>clanhb</i>. DOUBLE PRECISION for <i>zlanhb</i>. Workspace array, DIMENSION $\max(1, lwork)$, where $lwork \geq n$ when <i>norm</i> = 'I' or '1' or 'O'; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for <i>slanhb</i> / <i>clanhb</i>

DOUBLE PRECISION for dlanhb/zlanhb
Value returned by the function.

?lanzp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a symmetric matrix supplied in packed form.

Syntax

```
val = slansp( norm, uplo, n, ap, work )
val = dlansp( norm, uplo, n, ap, work )
val = clansp( norm, uplo, n, ap, work )
val = zlansp( norm, uplo, n, ap, work )
```

Description

The function ?lanzp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix *A*, supplied in packed form.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norml}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is supplied. If <i>uplo</i> = 'U': Upper triangular part of <i>A</i> is supplied

If *uplo* = 'L': Lower triangular part of *A* is supplied.

n INTEGER. The order of the matrix *A*. $n \geq 0$. When $n = 0$, *zlan*sp is set to zero.

ap REAL for slansp
DOUBLE PRECISION for dlansp
COMPLEX for clansp
COMPLEX*16 for zlan

Array, DIMENSION $(n(n+1)/2)$.
The upper or lower triangle of the symmetric matrix *A*, packed columnwise in a linear array. The *j*-th column of *A* is stored in the array *ap* as follows:

if *uplo* = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;
if *uplo* = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

work REAL for slansp and clansp.
DOUBLE PRECISION for dlansp and zlan

Workspace array, DIMENSION $(\max(1, lwork))$, where $lwork \geq n$ when *norm* = 'I' or '1' or 'O'; otherwise, *work* is not referenced.

Output Parameters

val REAL for slansp/clansp
DOUBLE PRECISION for dlansp/zlan

Value returned by the function.

?lanhp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix supplied in packed form.

Syntax

```
val = clanhp( norm, uplo, n, ap, work )
val = zlanhp( norm, uplo, n, ap, work )
```

Description

The function ?lanhp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A , supplied in packed form.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix A is supplied. If <i>uplo</i> = 'U': Upper triangular part of A is supplied If <i>uplo</i> = 'L': Lower triangular part of A is supplied.
<i>n</i>	INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, ?lanhp is set to zero.
<i>ap</i>	COMPLEX for clanhp. COMPLEX*16 for zlanhp.

Array, DIMENSION $(n(n+1)/2)$. The upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array ap as follows:

if $uplo = 'U'$, $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$;
 if $uplo = 'L'$, $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

work

REAL for `clanhp`.

DOUBLE PRECISION for `zlanhp`.

Workspace array, DIMENSION $(\max(1, lwork))$, where

$lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise, *work* is not referenced.

Output Parameters

val

REAL for `clanhp`.

DOUBLE PRECISION for `zlanhp`.

Value returned by the function.

?lanst/?lanht

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or complex Hermitian tridiagonal matrix.

Syntax

`val = slanst( norm, n, d, e )`

`val = dlanst( norm, n, d, e )`

`val = clanht( norm, n, d, e )`

`val = zlanht( norm, n, d, e )`

Description

The functions `?lanst/?lanht` return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real symmetric or a complex Hermitian tridiagonal matrix A .

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>n</i>	INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <code>?lanst/?lanht</code> is set to zero.
<i>d</i>	REAL for <code>slanst/clanht</code> DOUBLE PRECISION for <code>dlanst/zlanht</code> Array, DIMENSION (n). The diagonal elements of A.
<i>e</i>	REAL for <code>slanst</code> DOUBLE PRECISION for <code>dlanst</code> COMPLEX for <code>clanht</code> COMPLEX*16 for <code>zlanht</code> Array, DIMENSION ($n-1$). The ($n-1$) sub-diagonal or super-diagonal elements of A.

Output Parameters

<i>val</i>	REAL for <code>slanst/clanht</code> DOUBLE PRECISION for <code>dlanst/zlanht</code> Value returned by the function.

?lansy

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax

```
val = slansy( norm, uplo, n, a, lda, work )
val = dlansy( norm, uplo, n, a, lda, work )
val = clansy( norm, uplo, n, a, lda, work )
val = zlansy( norm, uplo, n, a, lda, work )
```

Description

The function ?lansy returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is to be referenced. = 'U': Upper triangular part of <i>A</i> is referenced. = 'L': Lower triangular part of <i>A</i> is referenced
<i>n</i>	INTEGER. The order of the matrix <i>A</i>. $n \geq 0$. When $n = 0$, ?lansy is set to zero.

a REAL for slansy
 DOUBLE PRECISION for dlansy
 COMPLEX for clansy
 COMPLEX*16 for zlansy
 Array, DIMENSION (*lda*,*n*). The symmetric matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*.
lda ≥ max(*n*,1).

work REAL for slansy and clansy.
 DOUBLE PRECISION for dlansy and zlansy.
 Workspace array, DIMENSION (max(1, *lwork*)), where
lwork ≥ *n* when *norm* = 'I' or '1' or 'O'; otherwise,
work is not referenced.

Output Parameters

val REAL for slansy/clansy
 DOUBLE PRECISION for dlansy/zlansy
 Value returned by the function.

?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

Syntax

```
val = clanhe( norm, uplo, n, a, lda, work )
val = zlanhe( norm, uplo, n, a, lda, work )
```

Description

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is to be referenced. = 'U': Upper triangular part of <i>A</i> is referenced. = 'L': Lower triangular part of <i>A</i> is referenced
<i>n</i>	INTEGER. The order of the matrix <i>A</i>. $n \geq 0$. When $n = 0$, <code>?lanhe</code> is set to zero.
<i>a</i>	COMPLEX for <code>clanhe</code>. COMPLEX*16 for <code>zlanhe</code>. Array, DIMENSION (<i>lda</i>,<i>n</i>). The Hermitian matrix <i>A</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(n, 1)$.
<i>work</i>	REAL for <code>clanhe</code>. DOUBLE PRECISION for <code>zlanhe</code>.

Workspace array, DIMENSION (max(1, lwork)) , where
 $lwork \geq n$ when $norm = 'I'$ or $'1'$ or $'O'$; otherwise,
 $work$ is not referenced.

Output Parameters

val REAL for `clanhe`.
 DOUBLE PRECISION for `zlanhe`.
 Value returned by the function.

?lantb

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular band matrix.

Syntax

```
val = slantb( norm, uplo, diag, n, k, ab, ldab, work )
val = dlantb( norm, uplo, diag, n, k, ab, ldab, work )
val = clantb( norm, uplo, diag, n, k, ab, ldab, work )
val = zlantb( norm, uplo, diag, n, k, ab, ldab, work )
```

Description

The function `?lantb` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an n -by- n triangular band matrix A , with $(k + 1)$ diagonals.

Input Parameters

$norm$ CHARACTER*1. Specifies the value to be returned by the routine:
 = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),

	= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular.
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular.
<i>n</i>	INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <i>?lantb</i> is set to zero.
<i>k</i>	INTEGER. The number of super-diagonals of the matrix A if <i>uplo</i> = 'U', or the number of sub-diagonals of the matrix A if <i>uplo</i> = 'L'. $k \geq 0$.
<i>ab</i>	REAL for <i>slantb</i> DOUBLE PRECISION for <i>dlantb</i> COMPLEX for <i>clantb</i> COMPLEX*16 for <i>zlantb</i> Array, DIMENSION (<i>ldab</i>,<i>n</i>). The upper or lower triangular band matrix A, stored in the first $k+1$ rows of <i>ab</i>. The j-th column of A is stored in the j-th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(k+1+i-j, j) = a(i, j)$ for $\max(1, j-k) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = a(i, j)$ for $j \leq i \leq \min(n, j+k)$. Note that when <i>diag</i> = 'U', the elements of the array <i>ab</i> corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq k+1$.
<i>work</i>	REAL for <i>slantb</i> and <i>clantb</i>. DOUBLE PRECISION for <i>dlantb</i> and <i>zlantb</i>. Workspace array, DIMENSION ($\max(1, lwork)$), where

$lwork \geq n$ when $norm = 'I'$; otherwise, $work$ is not referenced.

Output Parameters

val REAL for slantb/clantb.
DOUBLE PRECISION for dlantb/zlantb.
Value returned by the function.

?lantp

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix supplied in packed form.

Syntax

```
val = slantp( norm, uplo, diag, n, ap, work )
val = dlantp( norm, uplo, diag, n, ap, work )
val = clantp( norm, uplo, diag, n, ap, work )
val = zlantp( norm, uplo, diag, n, ap, work )
```

Description

The function ?lantp returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a triangular matrix A , supplied in packed form.

Input Parameters

$norm$ CHARACTER*1. Specifies the value to be returned by the routine:
= 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A .
= '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
= 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),

	= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular.
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular.
<i>n</i>	INTEGER. The order of the matrix A. $n \geq 0$. When $n = 0$, <i>slantp</i> is set to zero.
<i>ap</i>	REAL for <i>slantp</i> DOUBLE PRECISION for <i>dlantp</i> COMPLEX for <i>clantp</i> COMPLEX*16 for <i>zlantp</i> Array, DIMENSION $(n(n+1)/2)$. The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array <i>ap</i> as follows: if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = a(i, j)$ for $1 \leq i \leq j$; if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = a(i, j)$ for $j \leq i \leq n$. Note that when <i>diag</i> = 'U', the elements of the array <i>ap</i> corresponding to the diagonal elements of the matrix A are not referenced, but are assumed to be one.
<i>work</i>	REAL for <i>slantp</i> and <i>clantp</i>. DOUBLE PRECISION for <i>dlantp</i> and <i>zlantp</i>. Workspace array, DIMENSION $(\max(1, lwork))$, where $lwork \geq n$ when <i>norm</i> = 'I' ; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for <i>slantp</i> / <i>clantp</i> .

DOUBLE PRECISION for dlantr/zlantr.
Value returned by the function.

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

Syntax

```
val = slantr( norm, uplo, diag, m, n, a, lda, work )
val = dlantr( norm, uplo, diag, m, n, a, lda, work )
val = clantr( norm, uplo, diag, m, n, a, lda, work )
val = zlantr( norm, uplo, diag, m, n, a, lda, work )
```

Description

The function ?lantr returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix *A*.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix <i>A</i>. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower trapezoidal. = 'U': Upper trapezoidal = 'L': Lower trapezoidal. Note that <i>A</i> is triangular instead of trapezoidal if $m = n$.

<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix <i>A</i> has unit diagonal. = 'N': Non-unit diagonal = 'U': Unit diagonal.
<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i>. $m \geq 0$, and if <i>uplo</i> = 'U', $m \leq n$. When $m = 0$, <i>?lantr</i> is set to zero.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i>. $n \geq 0$, and if <i>uplo</i> = 'L', $n \leq m$. When $n = 0$, <i>?lantr</i> is set to zero.
<i>a</i>	REAL for <i>slantr</i> DOUBLE PRECISION for <i>dlantr</i> COMPLEX for <i>clantr</i> COMPLEX*16 for <i>zlantr</i> Array, DIMENSION (<i>lda</i>,<i>n</i>). The trapezoidal matrix <i>A</i> (<i>A</i> is triangular if $m = n$). If <i>uplo</i> = 'U', the leading <i>m</i>-by-<i>n</i> upper trapezoidal part of the array <i>a</i> contains the upper trapezoidal matrix, and the strictly lower triangular part of <i>A</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>m</i>-by-<i>n</i> lower trapezoidal part of the array <i>a</i> contains the lower trapezoidal matrix, and the strictly upper triangular part of <i>A</i> is not referenced. Note that when <i>diag</i> = 'U', the diagonal elements of <i>A</i> are not referenced and are assumed to be one.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(m, 1)$.
<i>work</i>	REAL for <i>slantr/clantrp</i>. DOUBLE PRECISION for <i>dlantr/zlantr</i>. Workspace array, DIMENSION ($\max(1, lwork)$), where $lwork \geq m$ when <i>norm</i> = 'I' ; otherwise, <i>work</i> is not referenced.

Output Parameters

<i>val</i>	REAL for <i>slantr/clantrp</i> .

DOUBLE PRECISION for dlantr/zlantr.
Value returned by the function.

?lanv2

Computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form.

Syntax

```
call slanv2( a, b, c, d, rt1r, rt1i, rt2r, rt2i, cs, sn )
call dlanv2( a, b, c, d, rt1r, rt1i, rt2r, rt2i, cs, sn )
```

Description

The routine computes the Schur factorization of a real 2-by-2 nonsymmetric matrix in standard form:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} cs & -sn \\ sn & cs \end{bmatrix} \begin{bmatrix} aa & bb \\ cc & dd \end{bmatrix} \begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix}$$

where either

- 1.** $cc = 0$ so that aa and dd are real eigenvalues of the matrix, or
- 2.** $aa = dd$ and $bb*cc < 0$, so that $aa \pm \sqrt{bb*cc}$ are complex conjugate eigenvalues.

The routine was adjusted to reduce the risk of cancellation errors, when computing real eigenvalues, and to ensure, if possible, that $abs(rt1r) \geq abs(rt2r)$.

Input Parameters

a, b, c, d REAL for slanv2
 DOUBLE PRECISION for dlanv2.
 On entry, elements of the input matrix.

Output Parameters

a, b, c, d On exit, overwritten by the elements of the standardized Schur form.

rt1r, rt1i, rt2r, rt2i REAL for slantv2
 DOUBLE PRECISION for dlanv2.
 The real and imaginary parts of the eigenvalues.
 If the eigenvalues are a complex conjugate pair, *rt1i* > 0.

cs, sn REAL for slantv2
 DOUBLE PRECISION for dlanv2.
 Parameters of the rotation matrix.

?lapll

Measures the linear dependence of two vectors.

Syntax

```
call slapll( n, x, incx, Y, incy, ssmín )
call dlapll( n, x, incx, Y, incy, ssmín )
call clapll( n, x, incx, Y, incy, ssmín )
call zlapll( n, x, incx, Y, incy, ssmín )
```

Description

Given two column vectors *x* and *y* of length *n*, let

$A = (x \ y)$ be the *n*-by-2 matrix.

The routine ?lapll first computes the *QR* factorization of *A* as $A = Q \cdot R$ and then computes the SVD of the 2-by-2 upper triangular matrix *R*. The smaller singular value of *R* is returned in *ssmin*, which is used as the measurement of the linear dependency of the vectors *x* and *y*.

Input Parameters

n INTEGER. The length of the vectors *x* and *y*.

x REAL for slapll
 DOUBLE PRECISION for dlapll
 COMPLEX for clapll
 COMPLEX*16 for zlapll
 Array, DIMENSION (1+(*n*-1) *incx*).
 On entry, *x* contains the *n*-vector *x*.

y REAL for slapll
 DOUBLE PRECISION for dlapll
 COMPLEX for clapll
 COMPLEX*16 for zlapll
 Array, DIMENSION (1+(*n*-1)*incy*).
 On entry, *y* contains the *n*-vector *y*.

incx INTEGER. The increment between successive elements of *x*; *incx* > 0.

incy INTEGER. The increment between successive elements of *y*; *incy* > 0.

Output Parameters

x On exit, *x* is overwritten.

y On exit, *y* is overwritten.

ssmin REAL for slapll/clapll
 DOUBLE PRECISION for dlapll/zlapll
 The smallest singular value of the *n*-by-2 matrix $A = \begin{pmatrix} x & y \end{pmatrix}$.

?lapmt

Performs a forward or backward permutation of the columns of a matrix.

Syntax

```
call slapmt( forwr, m, n, x, ldx, k )
call dlapmt( forwr, m, n, x, ldx, k )
call clapmt( forwr, m, n, x, ldx, k )
call zlapmt( forwr, m, n, x, ldx, k )
```

Description

The routine ?lapmt rearranges the columns of the *m*-by-*n* matrix *X* as specified by the permutation $k(1), k(2), \dots, k(n)$ of the integers $1, \dots, n$.

If *forwr* = .TRUE., forward permutation:

$X(*, k(j))$ is moved to $X(*, j)$ for $j=1, 2, \dots, n$.

If `forwrđ = .FALSE.`, backward permutation:

$X(*, j)$ is moved to $X(*, k(j))$ for $j = 1, 2, \dots, n$.

Input Parameters

<code>forwrđ</code>	LOGICAL. If <code>forwrđ = .TRUE.</code> , forward permutation If <code>forwrđ = .FALSE.</code> , backward permutation
<code>m</code>	INTEGER. The number of rows of the matrix X . $m \geq 0$.
<code>n</code>	INTEGER. The number of columns of the matrix X . $n \geq 0$.
<code>x</code>	REAL for <code>slapmt</code> DOUBLE PRECISION for <code>dlapmt</code> COMPLEX for <code>clapmt</code> COMPLEX*16 for <code>zlapmt</code> Array, DIMENSION (<code>ldx</code> , <code>n</code>). On entry, the m -by- n matrix X .
<code>ldx</code>	INTEGER. The leading dimension of the array X , $ldx \geq \max(1, m)$.
<code>k</code>	INTEGER. Array, DIMENSION (<code>n</code>). On entry, <code>k</code> contains the permutation vector and is used as internal workspace.

Output Parameters

<code>x</code>	On exit, <code>x</code> contains the permuted matrix X .
<code>k</code>	On exit, <code>k</code> is reset to its original value.

?lapy2

Returns $\sqrt{x^2 + y^2}$.

Syntax

`val = slap2( x, y )`

`val = dlapy2( x, y )`

Description

The function `?lapy2` returns $\sqrt{x^2 + y^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y REAL for slapy2
DOUBLE PRECISION for dlapy2
Specify the input values x and y .

Output Parameters

val REAL for slapy2
DOUBLE PRECISION for dlapy2.
Value returned by the function.

?lapy3

Returns $\text{sqrt}(x^2+y^2+z^2)$.

Syntax

```
val = slapy3( x, y, z )  
val = dlapy3( x, y, z )
```

Description

The function ?lapy3 returns $\text{sqrt}(x^2+y^2+z^2)$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y, z REAL for slapy3
DOUBLE PRECISION for dlapy3
Specify the input values x, y and z .

Output Parameters

val REAL for slapy3
DOUBLE PRECISION for dlapy3.
Value returned by the function.

?laqgb

Scales a general band matrix, using row and column scaling factors computed by ?gbequ.

Syntax

```
call slaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call dlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call claqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
call zlaqgb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, equed )
```

Description

The routine equilibrates a general m -by- n band matrix A with kl subdiagonals and ku superdiagonals using the row and column scaling factors in the vectors r and c .

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A . $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A . $ku \geq 0$.
ab	REAL for slaqgb DOUBLE PRECISION for dlaqgb COMPLEX for claqgb COMPLEX*16 for zlaqgb Array, DIMENSION ($ldab, n$). On entry, the matrix A in band storage, in rows 1 to $kl+ku+1$. The j -th column of A is stored in the j -th column of the array ab as follows: $ab(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.
$ldab$	INTEGER. The leading dimension of the array ab . $lda \geq kl+ku+1$.

<i>amax</i>	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Absolute value of largest matrix entry.
<i>r, c</i>	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Arrays $r(m)$, $c(n)$. Contain the row and column scale factors for A , respectively.
<i>rowcnd</i>	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Ratio of the smallest $r(i)$ to the largest $r(i)$.
<i>colcnd</i>	REAL for slaqgb/claqgb DOUBLE PRECISION for dlaqgb/zlaqgb Ratio of the smallest $c(i)$ to the largest $c(i)$.

Output Parameters

<i>ab</i>	On exit, the equilibrated matrix, in the same storage format as A . See <i>equed</i> for the form of the equilibrated matrix.
<i>equed</i>	CHARACTER*1. Specifies the form of equilibration that was done. If <i>equed</i> = 'N': No equilibration If <i>equed</i> = 'R': Row equilibration, that is, A has been premultiplied by $\text{diag}(r)$. If <i>equed</i> = 'C': Column equilibration, that is, A has been postmultiplied by $\text{diag}(c)$. If <i>equed</i> = 'B': Both row and column equilibration, that is, A has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If $\text{rowcnd} < \text{thresh}$, row scaling is done, and if $\text{colcnd} < \text{thresh}$, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If $\text{amax} > \text{large}$ or $\text{amax} < \text{small}$, row scaling is done.

?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by ?geequ.

Syntax

```
call slaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call dlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call claqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
call zlaqge( m, n, a, lda, r, c, rowcnd, colcnd, amax, equed )
```

Description

The routine equilibrates a general m -by- n matrix A using the row and column scaling factors in the vectors r and c .

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
a	REAL for slaqge DOUBLE PRECISION for dlaqge COMPLEX for claqge COMPLEX*16 for zlaqge Array, DIMENSION (lda, n). On entry, the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(m, 1)$.
r	REAL for slangge/claqge DOUBLE PRECISION for dlaqge/zlaqge Array, DIMENSION (m). The row scale factors for A .
c	REAL for slangge/claqge DOUBLE PRECISION for dlaqge/zlaqge Array, DIMENSION (n). The column scale factors for A .
$rowcnd$	REAL for slangge/claqge

colcnd DOUBLE PRECISION for dlaqge/zlaqge
Ratio of the smallest $r(i)$ to the largest $r(i)$.

amax REAL for slangge/claqge
DOUBLE PRECISION for dlaqge/zlaqge
Ratio of the smallest $c(i)$ to the largest $c(i)$.

REAL for slangge/claqge
DOUBLE PRECISION for dlaqge/zlaqge
Absolute value of largest matrix entry.

Output Parameters

a On exit, the equilibrated matrix.
See *equed* for the form of the equilibrated matrix.

equed CHARACTER*1.
Specifies the form of equilibration that was done.
If *equed* = 'N': No equilibration
If *equed* = 'R': Row equilibration, that is, A has been premultiplied by $\text{diag}(r)$.
If *equed* = 'C': Column equilibration, that is, A has been postmultiplied by $\text{diag}(c)$.
If *equed* = 'B': Both row and column equilibration, that is, A has been replaced by $\text{diag}(r) * A * \text{diag}(c)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if row or column scaling should be done based on the ratio of the row or column scaling factors. If *rowcnd* < *thresh*, row scaling is done, and if *colcnd* < *thresh*, column scaling is done. *large* and *small* are threshold values used to decide if row scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, row scaling is done.

?laqhb

Scales a Hermetian band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call claqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

```
call zlaqhb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Description

The routine equilibrates a Hermetian band matrix A using the scaling factors in the vector s .

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix A is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix A if <i>uplo</i> = 'U', or the number of sub-diagonals if <i>uplo</i> = 'L'. $kd \geq 0$.
<i>ab</i>	COMPLEX for claqhb COMPLEX*16 for zlaqhb Array, DIMENSION (<i>ldab</i> , <i>n</i>). On entry, the upper or lower triangle of the band matrix A , stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> .

ldab $\geq$ *kd*+1.

scond REAL for `claqsb`
 DOUBLE PRECISION for `zlaqsb`
 Ratio of the smallest $s(i)$ to the largest $s(i)$.

amax REAL for `claqsb`
 DOUBLE PRECISION for `zlaqsb`
 Absolute value of largest matrix entry.

Output Parameters

ab On exit, if *info* = 0, the triangular factor *U* or *L* from the Cholesky factorization $A = U' * U$ or $A = L * L'$ of the band matrix *A*, in the same storage format as *A*.

s REAL for `claqsb`
 DOUBLE PRECISION for `zlaqsb`
 Array, DIMENSION (*n*). The scale factors for *A*.

equed CHARACTER*1.
 Specifies whether or not equilibration was done.
 If *equed* = 'N': No equilibration.
 If *equed* = 'Y': Equilibration was done, that is, *A* has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If *scond* < *thresh*, scaling is done.

The values *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If *amax* > *large* or *amax* < *small*, scaling is done.

?laqp2

Computes a QR factorization with column pivoting of the matrix block.

Syntax

```
call slaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call dlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call claqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
call zlaqp2( m, n, offset, a, lda, jpvt, tau, vn1, vn2, work )
```

Description

The routine computes a QR factorization with column pivoting of the block $A(offset+1:m, 1:n)$. The block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> . $n \geq 0$.
<i>offset</i>	INTEGER. The number of rows of the matrix <i>A</i> that must be pivoted but no factorized. $offset \geq 0$.
<i>a</i>	REAL for slaqp2 DOUBLE PRECISION for dlaqp2 COMPLEX for claqp2 COMPLEX*16 for zlaqp2 Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.
<i>jpvt</i>	INTEGER. Array, DIMENSION (<i>n</i>). On entry, if $jpvt(i) \neq 0$, the <i>i</i> -th column of <i>A</i> is permuted to the front of A^*P (a leading column); if $jpvt(i) = 0$, the <i>i</i> -th column of <i>A</i> is a free column.
<i>vn1, vn2</i>	REAL for slaqp2/claqp2

work DOUBLE PRECISION for dlaqp2/zlaqp2
 Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.

REAL for slaqp2
 DOUBLE PRECISION for dlaqp2
 COMPLEX for claqp2
 COMPLEX*16 for zlaqp2 Workspace array, DIMENSION (n).

Output Parameters

a On exit, the upper triangle of block $A(offset+1:m, 1:n)$ is the triangular factor obtained; the elements in block $A(offset+1:m, 1:n)$ below the diagonal, together with the array *tau*, represent the orthogonal matrix Q as a product of elementary reflectors. Block $A(1:offset, 1:n)$ has been accordingly pivoted, but not factorized.

jpvt On exit, if $jpvt(i) = k$, then the i -th column of A^*P was the k -th column of A .

tau REAL for slaqp2
 DOUBLE PRECISION for dlaqp2
 COMPLEX for claqp2
 COMPLEX*16 for zlaqp2
 Array, DIMENSION ($\min(m, n)$).
 The scalar factors of the elementary reflectors.

vn1, vn2 Contain the vectors with the partial and exact column norms, respectively.

?laqps

Computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3.

Syntax

```
call slaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
call dlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
call claqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
call zlaqps( m, n, offset, nb, kb, a, lda, jpvt, tau, vn1, vn2, auxv, f, ldf
)
```

Description

This routine computes a step of QR factorization with column pivoting of a real m -by- n matrix A by using BLAS level 3. The routine tries to factorize NB columns from A starting from the row $offset+1$, and updates all of the matrix with BLAS level 3 routine ?gemm.

In some cases, due to catastrophic cancellations, ?laqps cannot factorize NB columns. Hence, the actual number of factorized columns is returned in kb .

Block $A(1:offset, 1:n)$ is accordingly pivoted, but not factorized.

Input Parameters

m	INTEGER. The number of rows of the matrix A . $m \geq 0$.
n	INTEGER. The number of columns of the matrix A . $n \geq 0$.
$offset$	INTEGER. The number of rows of A that have been factorized in previous steps.
nb	INTEGER. The number of columns to factorize.
a	REAL for slaqps DOUBLE PRECISION for dlaqps COMPLEX for claqps COMPLEX*16 for zlaqps

	Array, DIMENSION (lda, n). On entry, the m -by- n matrix A .
lda	INTEGER. The leading dimension of the array a . $lda \geq \max(1, m)$.
$jpvt$	INTEGER. Array, DIMENSION (n). If $jpvt(i) = k$ then column k of the full matrix A has been permuted into position i in AP.
$vn1, vn2$	REAL for slaqps/claqps DOUBLE PRECISION for dlaqps/zlaqps Arrays, DIMENSION (n) each. Contain the vectors with the partial and exact column norms, respectively.
$auxv$	REAL for slaqps DOUBLE PRECISION for dlaqps COMPLEX for claqps COMPLEX*16 for zlaqps Array, DIMENSION (nb). Auxiliary vector.
f	REAL for slaqps DOUBLE PRECISION for dlaqps COMPLEX for claqps COMPLEX*16 for zlaqps Array, DIMENSION (ldf, nb). Matrix $F' = L^* Y'^* A$.
ldf	INTEGER. The leading dimension of the array f . $ldf \geq \max(1, n)$.

Output Parameters

kb	INTEGER. The number of columns actually factorized.
a	On exit, block $A(offset+1:m, 1:kb)$ is the triangular factor obtained and block $A(1:offset, 1:n)$ has been accordingly pivoted, but no factorized. The rest of the matrix, block $A(offset+1:m, kb+1:n)$ has been updated.
$jpvt$	INTEGER array, DIMENSION (n). If $jpvt(i) = k$ then column k of the full matrix A has been permuted into position i in AP.
τ	REAL for slaqps DOUBLE PRECISION for dlaqps

	COMPLEX for claqps
	COMPLEX*16 for zlaqps
	Array, DIMENSION (kb). The scalar factors of the elementary reflectors.
$vn1, vn2$	The vectors with the partial and exact column norms, respectively.
$auxv$	Auxiliary vector.
f	Matrix $F' = L*Y'*A$.

?laqr0

Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.

Syntax

```
call slaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )

call dlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )

call claqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )

call zlaqr0( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )
```

Description

This routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H=Z*T*Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q*H*Q^H = (QZ)*H*(QZ)^H$.

Input Parameters

$wantt$	LOGICAL.

If *wantt* = .TRUE., the full Schur form *T* is required;
If *wantt* = .FALSE., only eigenvalues are required.

wantz LOGICAL.
If *wantz* = .TRUE., the matrix of Schur vectors *Z* is required;
If *wantz* = .FALSE., Schur vectors are not required.

n INTEGER. The order of the Hessenberg matrix *H*. ($n \geq 0$).

ilo, ihi INTEGER.
 It is assumed that *H* is already upper triangular in rows and columns 1:*ilo*-1 and *ihi*+1:*n*, and if *ilo* > 1 then $H(i\text{lo}, i\text{lo}-1) = 0$.
ilo and *ihi* are normally set by a previous call to *cgebal*, and then passed to *cgehrd* when the matrix output by *cgebal* is reduced to Hessenberg form. Otherwise, *ilo* and *ihi* should be set to 1 and *n*, respectively.
If $n > 0$, then $1 \leq ilo \leq ihi \leq n$.
If $n=0$, then $ilo=1$ and $ihi=0$

h REAL for slaqr0
 DOUBLE PRECISION for dlaqr0
 COMPLEX for claqr0
 COMPLEX*16 for zlaqr0.
Array, DIMENSION (*ldh*, *n*), contains the upper Hessenberg matrix *H*.

ldh INTEGER. The leading dimension of the array *h*. $ldh \geq \max(1, n)$.

iloz, ihiz INTEGER. Specify the rows of *Z* to which transformations must be applied if *wantz* is .TRUE., $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.

z REAL for slaqr0
 DOUBLE PRECISION for dlaqr0
 COMPLEX for claqr0
 COMPLEX*16 for zlaqr0.
Array, DIMENSION (*ldz*, *ihi*), contains the matrix *Z* if *wantz* is .TRUE.. If *wantz* is .FALSE., *z* is not referenced.

ldz INTEGER. The leading dimension of the array *z*.

If *wantz* is `.TRUE.`, then $ldz \geq \max(1, ihi_z)$. Otherwise, $ldz \geq 1$.

work REAL for `slaqr0`
 DOUBLE PRECISION for `dlaqr0`
 COMPLEX for `claqr0`
 COMPLEX*16 for `zlaqr0`.
 Workspace array with dimension *lwork*.

lwork INTEGER. The dimension of the array *work*.
 $lwork \geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$.
 It is recommended to use the workspace query to determine the optimal workspace size. If *lwork*=-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters *n*, *ilo*, and *ihi*. The estimate is returned in *work*(1). No error messages related to the *lwork* is issued by `xerbla`. Neither *H* nor *Z* are accessed.

Output Parameters

h If *info*=0, and *wantt* is `.TRUE.`, then *h* contains the upper quasi-triangular/triangular matrix *T* from the Schur decomposition (the Schur form).
 If *info*=0, and *wantt* is `.FALSE.`, then the contents of *h* are unspecified on exit.
 (The output values of *h* when *info* > 0 are given under the description of the *info* parameter below.)
 The routine may explicitly set *h*(*i*,*j*) for *i*>*j* and *j*=1,2,...*ilo*-1 or *j*=*ihi*+1, *ihi*+2,...*n*.

work(1) On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

w COMPLEX for `claqr0`
 COMPLEX*16 for `zlaqr0`.

Arrays, `DIMENSION(n)`. The computed eigenvalues of $h(i_{lo}:i_{hi}, i_{lo}:i_{hi})$ are stored in $w(i_{lo}:i_{hi})$. If `wantt` is `.TRUE.`, then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $w(i) = h(i, i)$.

`wr, wi` REAL for `slaqr0`
DOUBLE PRECISION for `dlaqr0`
Arrays, `DIMENSION(ihi)` each. The real and imaginary parts, respectively, of the computed eigenvalues of $h(i_{lo}:i_{hi}, i_{lo}:i_{hi})$ are stored in the $wr(i_{lo}:i_{hi})$ and $wi(i_{lo}:i_{hi})$. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi , say the i -th and $(i+1)$ -th, with $wi(i) > 0$ and $wi(i+1) < 0$. If `wantt` is `.TRUE.`, then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $wr(i) = h(i, i)$, and if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, then $wi(i) = \text{sqrt}(-h(i+1, i) * h(i, i+1))$.

`z` If `wantz` is `.TRUE.`, then $z(i_{lo}:i_{hi}, i_{loz}:i_{hiz})$ is replaced by $z(i_{lo}:i_{hi}, i_{loz}:i_{hiz}) * U$, where U is the orthogonal/unitary Schur factor of $h(i_{lo}:i_{hi}, i_{lo}:i_{hi})$. If `wantz` is `.FALSE.`, z is not referenced.
(The output values of z when `info` > 0 are given under the description of the `info` parameter below.)

`info` INTEGER.
= 0: the execution is successful.
> 0: if `info` = i , then the routine failed to compute all the eigenvalues. Elements $1:i_{lo}-1$ and $i+1:n$ of wr and wi contain those eigenvalues which have been successfully computed.
> 0: if `wantt` is `.FALSE.`, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns i_{lo} through `info` of the final output value of h .

```

> 0: if wantt is .TRUE., then (initial value of  $h$ )* $U$  =
 $U$ *(final value of  $h$ , where  $U$  is an orthogonal/unitary
matrix. The final value of  $h$  is upper Hessenberg and
quasi-triangular/triangular in rows and columns info+1
through ihi.
> 0: if wantz is .TRUE., then (final value of  $z$ (ilo:ihi,
ilo:ihiz))=(initial value of  $z$ (ilo:ihi, ilo:ihiz)* $U$ ,
where  $U$  is the orthogonal/unitary matrix in the previous
expression (regardless of the value of wantt).
> 0: if wantz is .FALSE., then  $z$  is not accessed.

```

1qr?

Sets a scalar multiple of the first column of the product of 2-by-2 or 3-by-3 matrix $\mathbb{H}$ and specified shifts.

Syntax

```
call slaqr1( n, h, ldh, srl, si1, sr2, si2, v )
call dlaqr1( n, h, ldh, srl, si1, sr2, si2, v )
call claqr1( n, h, ldh, s1, s2, v )
call zlaqr1( n, h, ldh, s1, s2, v )
```

Description

Given a 2-by-2 or 3-by-3 matrix H , this routine sets v to a scalar multiple of the first column of the product

$$K = (H - s1*I) * (H - s2*I), \text{ or } K = (H - (sr1 + i*si1)*I) * (H - (sr2 + i*si2)*I)$$

scaling to avoid overflows and most underflows.

It is assumed that either 1) $sr1 = sr2$ and $si1 = -si2$, or 2) $si1 = si2 = 0$.

This is useful for starting double implicit shift bulges in the QR algorithm.

Input Parameters

n INTEGER.

The order of the matrix H . n must be equal to 2 or 3.

<i>sr1, si2, sr2, si2</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 Shift values that define K in the formula above.
<i>s1, s2</i>	COMPLEX for claqr1 COMPLEX*16 for zlaqr1. Shift values that define K in the formula above.
<i>h</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 COMPLEX for claqr1 COMPLEX*16 for zlaqr1. Array, DIMENSION (<i>ldh</i> , <i>n</i>), contains 2-by-2 or 3-by-3 matrix H in the formula above.
<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling routine. $ldh \geq n$.

Output Parameters

<i>v</i>	REAL for slaqr1 DOUBLE PRECISION for dlaqr1 COMPLEX for claqr1 COMPLEX*16 for zlaqr1. Array with dimension (<i>n</i>). A scalar multiple of the first column of the matrix K in the formula above.

?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call dlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call claqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call zlaqr2( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
```

Description

This routine accepts as input an upper Hessenberg matrix H and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

This subroutine is identical to ?laqr3 except that it avoids recursion by calling ?lahqr instead of ?laqr4.

Input Parameters

<code>wantt</code>	LOGICAL. If <code>wantt = .TRUE.</code> , then the Hessenberg matrix H is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine). If <code>wantt = .FALSE.</code> , then only enough of H is updated to preserve the eigenvalues.
<code>wantz</code>	LOGICAL.

If *wantz* = *.TRUE.*, then the orthogonal/unitary matrix *z* is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine). If *wantz* = *.FALSE.*, then *z* is not referenced.

n INTEGER. The order of the Hessenberg matrix *H* and (if *wantz* = *.TRUE.*) the order of the orthogonal/unitary matrix *Z*.

ktop INTEGER.
It is assumed that either *ktop*=1 or *h*(*ktop*,*ktop*-1)=0. *ktop* and *kbot* together determine an isolated block along the diagonal of the Hessenberg matrix.

kbot INTEGER.
It is assumed without a check that either *kbot*=*n* or *h*(*kbot*+1,*kbot*)=0. *ktop* and *kbot* together determine an isolated block along the diagonal of the Hessenberg matrix.

nw INTEGER.
Size of the deflation window. $1 \leq nw \leq (kbot-ktop+1)$.

h REAL for slaqr2
DOUBLE PRECISION for dlaqr2
COMPLEX for claqr2
COMPLEX*16 for zlaqr2.
Array, DIMENSION (*ldh*, *n*), on input the initial *n*-by-*n* section of *h* stores the Hessenberg matrix *H* undergoing aggressive early deflation.

ldh INTEGER. The leading dimension of the array *h* just as declared in the calling subroutine. *ldh* ≥ *n*.

iloz, *ihiz* INTEGER. Specify the rows of *z* to which transformations must be applied if *wantz* is *.TRUE.*. $1 \leq iloz \leq ihiz \leq n$.

z REAL for slaqr2
DOUBLE PRECISION for dlaqr2
COMPLEX for claqr2
COMPLEX*16 for zlaqr2.
Array, DIMENSION (*ldz*, *ihi*), contains the matrix *z* if *wantz* is *.TRUE.*. If *wantz* is *.FALSE.*, then *z* is not referenced.

<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling subroutine. $ldz \geq 1$.
<i>v</i>	REAL for slaqr2 DOUBLE PRECISION for dlaqr2 COMPLEX for claqr2 COMPLEX*16 for zlaqr2. Workspace array with dimension (ldv, nw) . An <i>nw</i> -by- <i>nw</i> work array.
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling subroutine. $ldv \geq nw$.
<i>nh</i>	INTEGER. The number of column of <i>t</i> . $nh \geq nw$.
<i>t</i>	REAL for slaqr2 DOUBLE PRECISION for dlaqr2 COMPLEX for claqr2 COMPLEX*16 for zlaqr2. Workspace array with dimension (ldt, nw) .
<i>ldt</i>	INTEGER. The leading dimension of the array <i>t</i> just as declared in the calling subroutine. $ldt \geq nw$.
<i>nv</i>	INTEGER. The number of rows of work array <i>wv</i> available for workspace. $nv \geq nw$.
<i>wv</i>	REAL for slaqr2 DOUBLE PRECISION for dlaqr2 COMPLEX for claqr2 COMPLEX*16 for zlaqr2. Workspace array with dimension $(ldwv, nw)$.
<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling subroutine. $ldwv \geq nw$.
<i>work</i>	REAL for slaqr2 DOUBLE PRECISION for dlaqr2 COMPLEX for claqr2 COMPLEX*16 for zlaqr2. Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> .

$lwork=2*nw$) is sufficient, but for the optimal performance a greater workspace may be required.

If $lwork=-1$, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters n , nw , $ktop$, and $kbot$. The estimate is returned in $work(1)$. No error messages related to the $lwork$ is issued by `xerbla`. Neither H nor Z are accessed.

Output Parameters

h	On output h has been transformed by an orthogonal/unitary similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
$work(1)$	On exit $work(1)$ is set to an estimate of the optimal value of $lwork$ for the given values of the input parameters n , nw , $ktop$, and $kbot$.
z	If $wantz$ is <code>.TRUE.</code> , then the orthogonal/unitary similarity transformation is accumulated into $z(ihoz:ihiz, ilo:ihi)$ from the right. If $wantz$ is <code>.FALSE.</code> , then z is unreferenced.
nd	INTEGER. The number of converged eigenvalues uncovered by the routine.
ns	INTEGER. The number of unconverged, that is approximate eigenvalues returned in sr , si or in sh that may be used as shifts by the calling subroutine.
sh	COMPLEX for <code>claqr2</code> COMPLEX*16 for <code>zlaqr2</code> . Arrays, DIMENSION ($kbot$). The approximate eigenvalues that may be used for shifts are stored in the $sh(kbot-nd-ns+1)$ through the $sh(kbot-nd)$. The converged eigenvalues are stored in the $sh(kbot-nd+1)$ through the $sh(kbot)$.
sr, si	REAL for <code>slaqr2</code> DOUBLE PRECISION for <code>dlaqr2</code> Arrays, DIMENSION ($kbot$) each.

The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the $sr(kbot-nd-ns+1)$ through the $sr(kbot-nd)$, and $si(kbot-nd-ns+1)$ through the $si(kbot-nd)$, respectively. The real and imaginary parts of converged eigenvalues are stored in the $sr(kbot-nd+1)$ through the $sr(kbot)$, and $si(kbot-nd+1)$ through the $si(kbot)$, respectively.

?laqr3

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
call slaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call dlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sr, si, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call claqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )

call zlaqr3( wantt, wantz, n, ktop, kbot, nw, h, ldh, iloz, ihiz, z, ldz, ns,
nd, sh, v, ldv, nh, t, ldt, nv, wv, ldwv, work, lwork )
```

Description

This routine accepts as input an upper Hessenberg matrix H and performs an orthogonal/unitary similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H has been overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal/unitary similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

Input Parameters

`wantt` LOGICAL.

If *wantt* = `.TRUE.`, then the Hessenberg matrix *H* is fully updated so that the quasi-triangular/triangular Schur factor may be computed (in cooperation with the calling subroutine).

If *wantt* = `.FALSE.`, then only enough of *H* is updated to preserve the eigenvalues.

wantz LOGICAL.
If *wantz* = `.TRUE.`, then the orthogonal/unitary matrix *Z* is updated so that the orthogonal/unitary Schur factor may be computed (in cooperation with the calling subroutine).
If *wantz* = `.FALSE.`, then *Z* is not referenced.

n INTEGER. The order of the Hessenberg matrix *H* and (if *wantz* = `.TRUE.`) the order of the orthogonal/unitary matrix *Z*.

ktop INTEGER.
It is assumed that either *ktop*=1 or *h*(*ktop*,*ktop*-1)=0. *ktop* and *kbot* together determine an isolated block along the diagonal of the Hessenberg matrix.

kbot INTEGER.
It is assumed without a check that either *kbot*=*n* or *h*(*kbot*+1,*kbot*)=0. *ktop* and *kbot* together determine an isolated block along the diagonal of the Hessenberg matrix.

nw INTEGER.
Size of the deflation window. $1 \leq nw \leq (kbot - ktop + 1)$.

h REAL for slaqr3
DOUBLE PRECISION for dlaqr3
COMPLEX for claqr3
COMPLEX*16 for zlaqr3.
Array, DIMENSION (*ldh*, *n*), on input the initial *n*-by-*n* section of *h* stores the Hessenberg matrix *H* undergoing aggressive early deflation.

ldh INTEGER. The leading dimension of the array *h* just as declared in the calling subroutine. *ldh* ≥ *n*.

iloz, *ihiz* INTEGER. Specify the rows of *Z* to which transformations must be applied if *wantz* is `.TRUE.`. $1 \leq iloz \leq ihiz \leq n$.

<i>z</i>	REAL for slaqr3 DOUBLE PRECISION for dlaqr3 COMPLEX for claqr3 COMPLEX*16 for zlaqr3. Array, DIMENSION (<i>ldz</i>, <i>ihi</i>), contains the matrix <i>z</i> if <i>wantz</i> is .TRUE.. If <i>wantz</i> is .FALSE., then <i>z</i> is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling subroutine. <i>ldz</i>≥1.
<i>v</i>	REAL for slaqr3 DOUBLE PRECISION for dlaqr3 COMPLEX for claqr3 COMPLEX*16 for zlaqr3. Workspace array with dimension (<i>ldv</i>, <i>nw</i>). An <i>nw</i>-by-<i>nw</i> work array.
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling subroutine. <i>ldv</i>≥<i>nw</i>.
<i>nh</i>	INTEGER. The number of column of <i>t</i>. <i>nh</i>≥<i>nw</i>.
<i>t</i>	REAL for slaqr3 DOUBLE PRECISION for dlaqr3 COMPLEX for claqr3 COMPLEX*16 for zlaqr3. Workspace array with dimension (<i>ldt</i>, <i>nw</i>).
<i>ldt</i>	INTEGER. The leading dimension of the array <i>t</i> just as declared in the calling subroutine. <i>ldt</i>≥<i>nw</i>.
<i>nv</i>	INTEGER. The number of rows of work array <i>wv</i> available for workspace. <i>nv</i>≥<i>nw</i>.
<i>wv</i>	REAL for slaqr3 DOUBLE PRECISION for dlaqr3 COMPLEX for claqr3 COMPLEX*16 for zlaqr3. Workspace array with dimension (<i>ldwv</i>, <i>nw</i>).
<i>ldwv</i>	INTEGER. The leading dimension of the array <i>wv</i> just as declared in the calling subroutine. <i>ldwv</i>≥<i>nw</i>.

work REAL for slaqr3
 DOUBLE PRECISION for dlaqr3
 COMPLEX for claqr3
 COMPLEX*16 for zlaqr3.
 Workspace array with dimension *lwork*.

lwork INTEGER. The dimension of the array *work*.
lwork=2**nw*) is sufficient, but for the optimal performance
 a greater workspace may be required.
 If *lwork*=-1, then the routine performs a workspace query:
 it estimates the optimal workspace size for the given values
 of the input parameters *n*, *nw*, *ktop*, and *kbot*. The estimate
 is returned in *work*(1). No error messages related to the
lwork is issued by xerbla. Neither *H* nor *Z* are accessed.

Output Parameters

h On output *h* has been transformed by an orthogonal/unitary
 similarity transformation, perturbed, and the returned to
 Hessenberg form that (it is to be hoped) has some zero
 subdiagonal entries.

work(1) On exit *work*(1) is set to an estimate of the optimal value
 of *lwork* for the given values of the input parameters *n*,
nw, *ktop*, and *kbot*.

z If *wantz* is .TRUE., then the orthogonal/unitary similarity
 transformation is accumulated into *z*(*iloz:ihiz*, *ilo:ihi*)
 from the right.
 If *wantz* is .FALSE., then *z* is unreferenced.

nd INTEGER. The number of converged eigenvalues uncovered
 by the routine.

ns INTEGER. The number of unconverged, that is approximate
 eigenvalues returned in *sr*, *si* or in *sh* that may be used
 as shifts by the calling subroutine.

sh COMPLEX for claqr3
 COMPLEX*16 for zlaqr3.
 Arrays, DIMENSION (*kbot*).

The approximate eigenvalues that may be used for shifts are stored in the `sh(kbot-nd-ns+1)` through the `sh(kbot-nd)`.

The converged eigenvalues are stored in the `sh(kbot-nd+1)` through the `sh(kbot)`.

`sr, si` REAL for `slaqr3`
 DOUBLE PRECISION for `dlaqr3`
 Arrays, DIMENSION (`kbot`) each.

The real and imaginary parts of the approximate eigenvalues that may be used for shifts are stored in the `sr(kbot-nd-ns+1)` through the `sr(kbot-nd)`, and `si(kbot-nd-ns+1)` through the `si(kbot-nd)`, respectively.

The real and imaginary parts of converged eigenvalues are stored in the `sr(kbot-nd+1)` through the `sr(kbot)`, and `si(kbot-nd+1)` through the `si(kbot)`, respectively.

?laqr4

Computes the eigenvalues of a Hessenberg matrix, and optionally the matrices from the Schur decomposition.

Syntax

```
call slaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )

call dlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, wr, wi, iloz, ihiz, z, ldz,
work, lwork, info )

call claqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )

call zlaqr4( wantt, wantz, n, ilo, ihi, h, ldh, w, iloz, ihiz, z, ldz, work,
lwork, info )
```

Description

This routine computes the eigenvalues of a Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z^* T^* Z^H$, where T is an upper quasi-triangular/triangular matrix (the Schur form), and Z is the orthogonal/unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal/unitary matrix Q so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal/unitary matrix Q : $A = Q^* H^* Q^H = (QZ)^* H^* (QZ)^H$.

This routine implements one level of recursion for `?laqr0`. It is a complete implementation of the small bulge multi-shift QR algorithm. It may be called by `?laqr0` and, for large enough deflation window size, it may be called by `?laqr3`. This routine is identical to `?laqr0` except that it calls `?laqr2` instead of `?laqr3`.

Input Parameters

wantt LOGICAL.
If *wantt* = .TRUE., the full Schur form T is required;
If *wantt* = .FALSE., only eigenvalues are required.

wantz LOGICAL.
If *wantz* = .TRUE., the matrix of Schur vectors Z is required;
If *wantz* = .FALSE., Schur vectors are not required.

n INTEGER. The order of the Hessenberg matrix H . ($n \geq 0$).

ilo, ihi INTEGER.
It is assumed that H is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$, and if $ilo > 1$ then $h(ilo, ilo-1) = 0$.
ilo and *ihi* are normally set by a previous call to `cgebal`, and then passed to `cgehrd` when the matrix output by `cgebal` is reduced to Hessenberg form. Otherwise, *ilo* and *ihi* should be set to 1 and n , respectively.
If $n > 0$, then $1 \leq ilo \leq ihi \leq n$.
If $n=0$, then $ilo=1$ and $ihi=0$

h REAL for `slaqr4`
DOUBLE PRECISION for `dlaqr4`
COMPLEX for `claqr4`
COMPLEX*16 for `zlaqr4`.
Array, DIMENSION (*ldh*, n), contains the upper Hessenberg matrix H .

ldh INTEGER. The leading dimension of the array h . $ldh \geq \max(1, n)$.

<i>iloz, ihiz</i>	INTEGER. Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>, $1 \leq iloz \leq ilo$; $ihiz \leq ihiz \leq n$.
<i>z</i>	REAL for slaqr4 DOUBLE PRECISION for dlaqr4 COMPLEX for claqr4 COMPLEX*16 for zlaqr4. Array, DIMENSION (<i>ldz</i>, <i>ihi</i>), contains the matrix <i>z</i> if <i>wantz</i> is <code>.TRUE.</code>. If <i>wantz</i> is <code>.FALSE.</code>, <i>z</i> is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i>. If <i>wantz</i> is <code>.TRUE.</code>, then $ldz \geq \max(1, ihiz)$. Otherwise, $ldz \geq 1$.
<i>work</i>	REAL for slaqr4 DOUBLE PRECISION for dlaqr4 COMPLEX for claqr4 COMPLEX*16 for zlaqr4. Workspace array with dimension <i>lwork</i>.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i>. $lwork \geq \max(1, n)$ is sufficient, but for the optimal performance a greater workspace may be required, typically as large as $6*n$. It is recommended to use the workspace query to determine the optimal workspace size. If <i>lwork</i>=-1, then the routine performs a workspace query: it estimates the optimal workspace size for the given values of the input parameters <i>n</i>, <i>ilo</i>, and <i>ihi</i>. The estimate is returned in <i>work</i>(1). No error messages related to the <i>lwork</i> is issued by xerbla. Neither <i>H</i> nor <i>z</i> are accessed.

Output Parameters

<i>h</i>	If <i>info</i>=0, and <i>wantt</i> is <code>.TRUE.</code>, then <i>h</i> contains the upper quasi-triangular/triangular matrix <i>T</i> from the Schur decomposition (the Schur form). If <i>info</i>=0, and <i>wantt</i> is <code>.FALSE.</code>, then the contents of <i>h</i> are unspecified on exit.

(The output values of h when $info > 0$ are given under the description of the *info* parameter below.)
The routines may explicitly set $h(i,j)$ for $i > j$ and $j=1,2,\dots,ilo-1$ or $j=ihi+1, ihl+2,\dots,n$.

work(1) On exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

w COMPLEX for *claqr4*
COMPLEX*16 for *zlaqr4*.
Arrays, DIMENSION(*n*). The computed eigenvalues of $h(ilo:ihi, ilo:ihi)$ are stored in $w(ilo:ihi)$. If *wantt* is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $w(i) = h(i,i)$.

wr, wi REAL for *slaqr4*
DOUBLE PRECISION for *dlaqr4*
Arrays, DIMENSION(*ihi*) each. The real and imaginary parts, respectively, of the computed eigenvalues of $h(ilo:ihi, ilo:ihi)$ are stored in the $wr(ilo:ihi)$ and $wi(ilo:ihi)$. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of *wr* and *wi*, say the *i*-th and (*i*+1)-th, with $wi(i) > 0$ and $wi(i+1) < 0$. If *wantt* is .TRUE., then the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in h , with $wr(i) = h(i,i)$, and if $h(i:i+1, i:i+1)$ is a 2-by-2 diagonal block, then $wi(i) = \sqrt{-h(i+1,i) * h(i,i+1)}$.

z If *wantz* is .TRUE., then $z(ilo:ihi, iloz:ihiz)$ is replaced by $z(ilo:ihi, iloz:ihiz) * U$, where U is the orthogonal/unitary Schur factor of $h(ilo:ihi, ilo:ihi)$. If *wantz* is .FALSE., *z* is not referenced.
(The output values of z when $info > 0$ are given under the description of the *info* parameter below.)

info INTEGER.
= 0: the execution is successful.

> 0: if *info* = *i*, then the routine failed to compute all the eigenvalues. Elements 1:*ilo*-1 and *i*+1:*n* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

> 0: if *wantt* is *.FALSE.*, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns *ilo* through *info* of the final output value of *h*.

> 0: if *wantt* is *.TRUE.*, then (initial value of *h*)**U* = *U**(final value of *h*, where *U* is an orthogonal/unitary matrix. The final value of *h* is upper Hessenberg and quasi-triangular/triangular in rows and columns *info*+1 through *ihi*.

> 0: if *wantz* is *.TRUE.*, then (final value of *z*(*ilo:ihi*, *iloz:ihiz*))=(initial value of *z*(*ilo:ihi*, *iloz:ihiz*))**U*, where *U* is the orthogonal/unitary matrix in the previous expression (regardless of the value of *wantt*).

> 0: if *wantz* is *.FALSE.*, then *z* is not accessed.

?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
call slaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh,
            iloz, ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )

call dlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, sr, si, h, ldh,
            iloz, ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )

call claqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz,
            ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )

call zlaqr5( wantt, wantz, kacc22, n, ktop, kbot, nshfts, s, h, ldh, iloz,
            ihiz, z, ldz, v, ldv, u, ldu, nv, wv, ldwv, nh, wh, ldwh )
```

Description

This auxiliary routine called by ?laqr0 performs a single small-bulge multi-shift QR sweep.

Input Parameters

<i>wantt</i>	LOGICAL. <i>wantt</i> = .TRUE. if the quasi-triangular/triangular Schur factor is computed. <i>wantt</i> is set to .FALSE. otherwise.
<i>wantz</i>	LOGICAL. <i>wantz</i> = .TRUE. if the orthogonal/unitary Schur factor is computed. <i>wantz</i> is set to .FALSE. otherwise.
<i>kacc22</i>	INTEGER. Possible values are 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: the routine does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: the routine accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: the routine accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<i>n</i>	INTEGER. The order of the Hessenberg matrix <i>H</i> upon which the routine operates.
<i>ktop, kbot</i>	INTEGER. It is assumed without a check that either <i>ktop</i> =1 or $h(ktop, ktop-1)=0$, and either <i>kbot</i> = <i>n</i> or $h(kbot+1, kbot)=0$.
<i>nshfts</i>	INTEGER. Number of simultaneous shifts, must be positive and even.
<i>sr, si</i>	REAL for slaqr5 DOUBLE PRECISION for dlaqr5 Arrays, DIMENSION (<i>nshfts</i>) each. <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep.

<i>s</i>	COMPLEX for <code>claqr5</code> COMPLEX*16 for <code>zlaqr5</code>. Arrays, DIMENSION (<i>nshfts</i>). <i>s</i> contains the shifts of origin that define the multi-shift QR sweep.
<i>h</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> COMPLEX*16 for <code>zlaqr5</code>. Array, DIMENSION (<i>ldh</i>, <i>n</i>), on input contains the Hessenberg matrix.
<i>ldh</i>	INTEGER. The leading dimension of the array <i>h</i> just as declared in the calling routine. $ldh \geq \max(1, n)$.
<i>iloz, ihiz</i>	INTEGER. Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is <code>.TRUE.</code>. $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> COMPLEX*16 for <code>zlaqr5</code>. Array, DIMENSION (<i>ldz</i>, <i>ihi</i>), contains the matrix <i>z</i> if <i>wantz</i> is <code>.TRUE.</code>. If <i>wantz</i> is <code>.FALSE.</code>, then <i>z</i> is not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the array <i>z</i> just as declared in the calling routine. $ldz \geq n$.
<i>v</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> COMPLEX*16 for <code>zlaqr5</code>. Workspace array with dimension (<i>ldv</i>, <i>nshfts</i>/2).
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> just as declared in the calling routine. $ldv \geq 3$.
<i>u</i>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code>

	COMPLEX*16 for <code>zlaqr5</code> . Workspace array with dimension $(ldu, 3*nshfts-3)$.
<code>ldu</code>	INTEGER. The leading dimension of the array <code>u</code> just as declared in the calling routine. $ldu \geq 3*nshfts-3$.
<code>nh</code>	INTEGER. The number of column in the array <code>wh</code> available for workspace. $nh \geq 1$.
<code>wh</code>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> COMPLEX*16 for <code>zlaqr5</code> . Workspace array with dimension $(ldwh, nh)$
<code>ldwh</code>	INTEGER. The leading dimension of the array <code>wh</code> just as declared in the calling routine. $ldwh \geq 3*nshfts-3$
<code>nv</code>	INTEGER. The number of rows of the array <code>wv</code> available for workspace. $nv \geq 1$.
<code>wv</code>	REAL for <code>slaqr5</code> DOUBLE PRECISION for <code>dlaqr5</code> COMPLEX for <code>claqr5</code> COMPLEX*16 for <code>zlaqr5</code> . Workspace array with dimension $(ldwv, 3*nshfts-3)$.
<code>ldwv</code>	INTEGER. The leading dimension of the array <code>wv</code> just as declared in the calling routine. $ldwv \geq nv$.

Output Parameters

<code>h</code>	On output a multi-shift QR Sweep with shifts $sr(j)+i*si(j)$ or $s(j)$ is applied to the isolated diagonal block in rows and columns <code>k_{top}</code> through <code>k_{bot}</code> .
<code>z</code>	If <code>wantz</code> is <code>.TRUE.</code> , then the QR Sweep orthogonal/unitary similarity transformation is accumulated into <code>z(ilo:ihiz, ilo:ihi)</code> from the right. If <code>wantz</code> is <code>.FALSE.</code> , then <code>z</code> is unreferenced.

?laqsb

Scales a symmetric band matrix, using scaling factors computed by ?pbequ.

Syntax

```
call slaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call dlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call claqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
call zlaqsb( uplo, n, kd, ab, ldab, s, scond, amax, equed )
```

Description

The routine equilibrates a symmetric band matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix <i>A</i> if <i>uplo</i> = 'U', or the number of sub-diagonals if <i>uplo</i> = 'L'. $kd \geq 0$.
<i>ab</i>	REAL for slaqsb DOUBLE PRECISION for dlaqsb COMPLEX for claqsb COMPLEX*16 for zlaqsb Array, DIMENSION (<i>ldab</i> , <i>n</i>). On entry, the upper or lower triangle of the symmetric band matrix <i>A</i> , stored in the first <i>kd</i> +1 rows of the array. The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows:

	<pre> if uplo = 'U', ab(kd+1+i-j,j) = A(i,j) for max(1,j-kd) ≤ i ≤ j; if uplo = 'L', ab(1+i-j,j) = A(i,j) for j ≤ i ≤ min(n,j+kd). </pre>
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq kd+1$.
<i>s</i>	REAL for slaqsb/claqsb DOUBLE PRECISION for dlaqsb/zlaqsb Array, DIMENSION (<i>n</i>). The scale factors for <i>A</i>.
<i>scond</i>	REAL for slaqsb/claqsb DOUBLE PRECISION for dlaqsb/zlaqsb Ratio of the smallest $s(i)$ to the largest $s(i)$.
<i>amax</i>	REAL for slaqsb/claqsb DOUBLE PRECISION for dlaqsb/zlaqsb Absolute value of largest matrix entry.

Output Parameters

<i>ab</i>	On exit, if <i>info</i> = 0, the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A = U'^*U$ or $A = L*L'$ of the band matrix <i>A</i>, in the same storage format as <i>A</i>.
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If <i>equed</i> = 'N': No equilibration. If <i>equed</i> = 'Y': Equilibration was done, that is, <i>A</i> has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?laqsp

Scales a symmetric/Hermitian matrix in packed storage, using scaling factors computed by ?ppequ.

Syntax

```
call slaqsp( uplo, n, ap, s, scond, amax, equed )
call dlaqsp( uplo, n, ap, s, scond, amax, equed )
call claqsp( uplo, n, ap, s, scond, amax, equed )
call zlaqsp( uplo, n, ap, s, scond, amax, equed )
```

Description

The routine ?laqsp equilibrates a symmetric matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>ap</i>	REAL for slaqsp DOUBLE PRECISION for dlaqsp COMPLEX for claqsp COMPLEX*16 for zlaqsp Array, DIMENSION $(n(n+1)/2)$. On entry, the upper or lower triangle of the symmetric matrix <i>A</i> , packed columnwise in a linear array. The <i>j</i> -th column of <i>A</i> is stored in the array <i>ap</i> as follows: if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$; if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

s REAL for slaqsp/claqsp
 DOUBLE PRECISION for dlaqsp/zlaqsp
 Array, DIMENSION (*n*). The scale factors for *A*.

scond REAL for slaqsp/claqsp
 DOUBLE PRECISION for dlaqsp/zlaqsp
 Ratio of the smallest $s(i)$ to the largest $s(i)$.

amax REAL for slaqsp/claqsp
 DOUBLE PRECISION for dlaqsp/zlaqsp
 Absolute value of largest matrix entry.

Output Parameters

ap On exit, the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$, in the same storage format as *A*.

equed CHARACTER*1.
 Specifies whether or not equilibration was done.
 If *equed* = 'N': No equilibration.
 If *equed* = 'Y': Equilibration was done, that is, *A* has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by ?poequ.

Syntax

```
call slaqsy( uplo, n, a, lda, s, scond, amax, equed )
call dlaqsy( uplo, n, a, lda, s, scond, amax, equed )
call claqsy( uplo, n, a, lda, s, scond, amax, equed )
call zlaqsy( uplo, n, a, lda, s, scond, amax, equed )
```

Description

The routine equilibrates a symmetric matrix *A* using the scaling factors in the vector *s*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored. If <i>uplo</i> = 'U': upper triangular. If <i>uplo</i> = 'L': lower triangular.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>a</i>	REAL for slaqsy DOUBLE PRECISION for dlaqsy COMPLEX for claqsy COMPLEX*16 for zlaqsy Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the symmetric matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> .

	$lda \geq \max(n, 1)$.
<i>s</i>	REAL for slaqsy/claqsy DOUBLE PRECISION for dlaqsy/zlaqsy Array, DIMENSION (<i>n</i>). The scale factors for A.
<i>scond</i>	REAL for slaqsy/claqsy DOUBLE PRECISION for dlaqsy/zlaqsy Ratio of the smallest $s(i)$ to the largest $s(i)$.
<i>amax</i>	REAL for slaqsy/claqsy DOUBLE PRECISION for dlaqsy/zlaqsy Absolute value of largest matrix entry.

Output Parameters

<i>a</i>	On exit, if <i>equed</i> = 'Y', the equilibrated matrix: $\text{diag}(s) * A * \text{diag}(s)$.
<i>equed</i>	CHARACTER*1. Specifies whether or not equilibration was done. If <i>equed</i> = 'N': No equilibration. If <i>equed</i> = 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(s) * A * \text{diag}(s)$.

Application Notes

The routine uses internal parameters *thresh*, *large*, and *small*, which have the following meaning. *thresh* is a threshold value used to decide if scaling should be based on the ratio of the scaling factors. If $scond < thresh$, scaling is done. *large* and *small* are threshold values used to decide if scaling should be done based on the absolute size of the largest matrix element. If $amax > large$ or $amax < small$, scaling is done.

?laqtr

*Solves a real quasi-triangular system of equations,
or a complex quasi-triangular system of special
form, in real arithmetic.*

Syntax

```
call slaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
call dlaqtr( ltran, lreal, n, t, ldt, b, w, scale, x, work, info )
```

Description

The routine `?laqtr` solves the real quasi-triangular system

$\text{op}(T) * p = \text{scale} * c$, if $\text{lreal} = \text{.TRUE.}$

or the complex quasi-triangular systems

$\text{op}(T + iB) * (p+iq) = \text{scale} * (c+id)$, if $\text{lreal} = \text{.FALSE.}$

in real arithmetic, where T is upper quasi-triangular.

If $\text{lreal} = \text{.FALSE.}$, then the first diagonal block of T must be 1-by-1, B is the specially structured matrix

$$B = \begin{bmatrix} b_1 & b_2 & \dots & \dots & b_n \\ & W & & & \\ & & W & & \\ & & & \dots & \\ & & & & W \end{bmatrix}$$

$\text{op}(A) = A$ or A' , A' denotes the conjugate transpose of matrix A .

On input,

$$x = \begin{bmatrix} c \\ d \end{bmatrix}, \text{ on output } x = \begin{bmatrix} p \\ q \end{bmatrix}$$

This routine is designed for the condition number estimation in routine `?trsna`.

Input Parameters

ltran

LOGICAL.

On entry, *ltran* specifies the option of conjugate transpose:

= `.FALSE.`, $\text{op}(T + iB) = T + iB$,

$= .TRUE., \text{op}(T + iB) = (T + iB)'$.
lreal LOGICAL.
 On entry, *lreal* specifies the input matrix structure:
 $= .FALSE.,$ the input is complex
 $= .TRUE.,$ the input is real.

n INTEGER.
 On entry, *n* specifies the order of $T + iB$. $n \geq 0$.

t REAL for slaqtr
 DOUBLE PRECISION for dlaqtr
 Array, dimension (ldt, n) . On entry, *t* contains a matrix in Schur canonical form. If *lreal* = $.FALSE.,$ then the first diagonal block of *t* must be 1-by-1.

ldt INTEGER. The leading dimension of the matrix *T*.
 $ldt \geq \max(1, n)$.

b REAL for slaqtr
 DOUBLE PRECISION for dlaqtr
 Array, dimension (n) . On entry, *b* contains the elements to form the matrix *B* as described above. If *lreal* = $.TRUE.,$ *b* is not referenced.

w REAL for slaqtr
 DOUBLE PRECISION for dlaqtr
 On entry, *w* is the diagonal element of the matrix *B*.
 If *lreal* = $.TRUE.,$ *w* is not referenced.

x REAL for slaqtr
 DOUBLE PRECISION for dlaqtr
 Array, dimension $(2n)$. On entry, *x* contains the right hand side of the system.

work REAL for slaqtr
 DOUBLE PRECISION for dlaqtr
 Workspace array, dimension (n) .

Output Parameters

scale REAL for slaqtr
 DOUBLE PRECISION for dlaqtr
 On exit, *scale* is the scale factor.

<i>x</i>	On exit, <i>x</i> is overwritten by the solution.
<i>info</i>	INTEGER. If <i>info</i> = 0: successful exit. If <i>info</i> = 1: the some diagonal 1-by-1 block has been perturbed by a small number <i>smin</i> to keep nonsingularity. If <i>info</i> = 2: the some diagonal 2-by-2 block has been perturbed by a small number in ?1aln2 to keep nonsingularity.

NOTE. For higher speed, this routine does not check the inputs for errors.

?lar1v

Computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of tridiagonal matrix.

Syntax

```
call slar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

```
call dlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

```
call clar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

```
call zlar1v( n, b1, bn, lambda, d, l, ld, lld, pivmin, gaptol, z, wantnc,
negcnt, ztz, mingma, r, isuppz, nrminv, resid, rqcorr, work )
```

Description

The routine `?lar1v` computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $L * D * L^T - \lambda * I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude.

The following steps accomplish this computation :

- Stationary qd transform, $L^*D^*L^T - \lambda^*I = L(+)*D(+)*L(+)^T$
- Progressive qd transform, $L^*D^*L^T - \lambda^*I = U(-)*D(-)*U(-)^T$,
- Computation of the diagonal elements of the inverse of $L^*D^*L^T - \lambda^*I$ by combining the above transforms, and choosing r as the index where the diagonal of the inverse is (one of the) largest in magnitude.
- Computation of the (scaled) r -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

n	INTEGER. The order of the matrix $L^*D^*L^T$.
$b1$	INTEGER. First index of the submatrix of $L^*D^*L^T$.
bn	INTEGER. Last index of the submatrix of $L^*D^*L^T$.
$lambda$	REAL for slarlvc/clarlvc DOUBLE PRECISION for dlarlv/zlarlv The shift. To compute an accurate eigenvector, $lambda$ should be a good approximation to an eigenvalue of $L^*D^*L^T$.
l	REAL for slarlvc/clarlvc DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION $(n-1)$. The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix L , in elements 1 to $n-1$.
d	REAL for slarlvc/clarlvc DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION (n) . The n diagonal elements of the diagonal matrix D .
ld	REAL for slarlvc/clarlvc DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION $(n-1)$. The $n-1$ elements $L_i^*D_i$.
lld	REAL for slarlvc/clarlvc DOUBLE PRECISION for dlarlv/zlarlv Array, DIMENSION $(n-1)$. The $n-1$ elements $L_i^*L_i^*D_i$.

<i>pivmin</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The minimum pivot in the Sturm sequence.
<i>gaptol</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.
<i>z</i>	REAL for slarlv DOUBLE PRECISION for dlarlv COMPLEX for clarlv COMPLEX*16 for zlarlv Array, DIMENSION (<i>n</i>). All entries of <i>z</i> must be set to 0.
<i>wantnc</i>	LOGICAL. Specifies whether <i>negcnt</i> has to be computed.
<i>r</i>	INTEGER. The twist index for the twisted factorization used to compute <i>z</i> . On input, $0 \leq r \leq n$. If <i>r</i> is input as 0, <i>r</i> is set to the index where $(L^*D^*L^T - \lambda I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, <i>r</i> is unchanged.
<i>work</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Workspace array, DIMENSION (4* <i>n</i>).

Output Parameters

<i>z</i>	REAL for slarlv DOUBLE PRECISION for dlarlv COMPLEX for clarlv COMPLEX*16 for zlarlv Array, DIMENSION (<i>n</i>). The (scaled) <i>r</i> -th column of the inverse. <i>z</i> (<i>r</i>) is returned to be 1.
<i>negcnt</i>	INTEGER. If <i>wantnc</i> is .TRUE. then <i>negcnt</i> = the number of pivots < <i>pivmin</i> in the matrix factorization $L^*D^*L^T$, and <i>negcnt</i> = -1 otherwise.
<i>ztz</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The square of the 2-norm of <i>z</i> .

<i>mingma</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The reciprocal of the largest (in magnitude) diagonal element of the inverse of $L^*D^*L^T - \lambda I$.
<i>r</i>	On output, <i>r</i> is the twist index used to compute <i>z</i> . Ideally, <i>r</i> designates the position of the maximum entry in the eigenvector.
<i>isuppz</i>	INTEGER. Array, DIMENSION (2). The support of the vector in <i>z</i> , that is, the vector <i>z</i> is nonzero only in elements <i>isuppz</i> (1) through <i>isuppz</i> (2).
<i>nrminv</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv Equals $1/\sqrt{ztz}$.
<i>resid</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The residual of the FP vector. $resid = \text{ABS}(mingma)/\sqrt{ztz}$.
<i>rqcorr</i>	REAL for slarlv/clarlv DOUBLE PRECISION for dlarlv/zlarlv The Rayleigh Quotient correction to λ . $rqcorr = mingma/ztz$.

?lar2v

Applies a vector of plane rotations with real cosines and real/complex sines from both sides to a sequence of 2-by-2 symmetric/Hermitian matrices.

Syntax

```
call slar2v( n, x, y, z, incx, c, s, incc )
call dlar2v( n, x, y, z, incx, c, s, incc )
call clar2v( n, x, y, z, incx, c, s, incc )
call zlar2v( n, x, y, z, incx, c, s, incc )
```

Description

The routine `?lar2v` applies a vector of real/complex plane rotations with real cosines from both sides to a sequence of 2-by-2 real symmetric or complex Hermitian matrices, defined by the elements of the vectors `x`, `y` and `z`. For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i & z_i \\ \text{conjg}(z_i) & y_i \end{bmatrix} := \begin{bmatrix} c(i) & \text{conjg}(s(i)) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i & z_i \\ \text{conjg}(z_i) & y_i \end{bmatrix} \begin{bmatrix} c(i) & -\text{conjg}(s(i)) \\ s(i) & c(i) \end{bmatrix}$$

Input Parameters

<code>n</code>	INTEGER. The number of plane rotations to be applied.
<code>x, y, z</code>	REAL for <code>slar2v</code> DOUBLE PRECISION for <code>dlar2v</code> COMPLEX for <code>clar2v</code> COMPLEX*16 for <code>zlar2v</code> Arrays, DIMENSION $(1+(n-1)*incx)$ each. Contain the vectors <code>x</code> , <code>y</code> and <code>z</code> , respectively. For all flavors of <code>?lar2v</code> , elements of <code>x</code> and <code>y</code> are assumed to be real.
<code>incx</code>	INTEGER. The increment between elements of <code>x</code> , <code>y</code> , and <code>z</code> . $incx > 0$.
<code>c</code>	REAL for <code>slar2v/clar2v</code> DOUBLE PRECISION for <code>dlar2v/zlar2v</code> Array, DIMENSION $(1+(n-1)*incc)$. The cosines of the plane rotations.
<code>s</code>	REAL for <code>slar2v</code> DOUBLE PRECISION for <code>dlar2v</code> COMPLEX for <code>clar2v</code> COMPLEX*16 for <code>zlar2v</code> Array, DIMENSION $(1+(n-1)*incc)$. The sines of the plane rotations.
<code>incc</code>	INTEGER. The increment between elements of <code>c</code> and <code>s</code> . $incc > 0$.

Output Parameters

x, y, z Vectors x, y and z , containing the results of transform.

?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call slarf( side, m, n, v, incv, tau, c, ldc, work )
call dlarf( side, m, n, v, incv, tau, c, ldc, work )
call clarf( side, m, n, v, incv, tau, c, ldc, work )
call zlarf( side, m, n, v, incv, tau, c, ldc, work )
```

Description

The routine applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in the form

$$H = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then H is taken to be the unit matrix. For `clarf/zlarf`, to apply H' (the conjugate transpose of H), supply `conjg(tau)` instead of τ .

Input Parameters

$side$	CHARACTER*1. If $side = 'L'$: form $H*C$ If $side = 'R'$: form $C*H$.
m	INTEGER. The number of rows of the matrix C .
n	INTEGER. The number of columns of the matrix C .
v	REAL for <code>slarf</code> DOUBLE PRECISION for <code>dlarf</code> COMPLEX for <code>clarf</code> COMPLEX*16 for <code>zlarf</code> Array, DIMENSION

	$(1 + (m-1) * \text{abs}(\text{incv}))$ if <i>side</i> = 'L' or $(1 + (n-1) * \text{abs}(\text{incv}))$ if <i>side</i> = 'R'. The vector <i>v</i> in the representation of <i>H</i> . <i>v</i> is not used if <i>tau</i> = 0.
<i>incv</i>	INTEGER. The increment between elements of <i>v</i> . <i>incv</i> ≠ 0.
<i>tau</i>	REAL for slarf DOUBLE PRECISION for dlarf COMPLEX for clarf COMPLEX*16 for zlarf The value <i>tau</i> in the representation of <i>H</i> .
<i>c</i>	REAL for slarf DOUBLE PRECISION for dlarf COMPLEX for clarf COMPLEX*16 for zlarf Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>C</i> .
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $ldc \geq \max(1, m)$.
<i>work</i>	REAL for slarf DOUBLE PRECISION for dlarf COMPLEX for clarf COMPLEX*16 for zlarf Workspace array, DIMENSION (<i>n</i>) if <i>side</i> = 'L' or (<i>m</i>) if <i>side</i> = 'R'.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by the matrix $H * C$ if <i>side</i> = 'L', or $C * H$ if <i>side</i> = 'R'.

?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
call slarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )

call dlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )

call clarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )

call zlarfb( side, trans, direct, storev, m, n, k, v, ldv, t, ldt, c, ldc,
work, ldwork )
```

Description

The routine ?larfb applies a complex block reflector H or its transpose H' to a complex m -by- n matrix C from either left or right.

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': apply H or H' from the left If <i>side</i> = 'R': apply H or H' from the right
<i>trans</i>	CHARACTER*1. If <i>trans</i> = 'N': apply H (No transpose) If <i>trans</i> = 'C': apply H' (Conjugate transpose)
<i>direct</i>	CHARACTER*1. Indicates how H is formed from a product of elementary reflectors If <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) If <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Indicates how the vectors which define the elementary reflectors are stored:

	If <i>storev</i> = 'C': Column-wise If <i>storev</i> = 'R': Row-wise
<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> .
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. The order of the matrix <i>T</i> (equal to the number of elementary reflectors whose product defines the block reflector).
<i>v</i>	REAL for slarfb DOUBLE PRECISION for dlarfb COMPLEX for clarfb COMPLEX*16 for zlarfb Array, DIMENSION (<i>ldv</i>, <i>k</i>) if <i>storev</i> = 'C' (<i>ldv</i>, <i>m</i>) if <i>storev</i> = 'R' and <i>side</i> = 'L' (<i>ldv</i>, <i>n</i>) if <i>storev</i> = 'R' and <i>side</i> = 'R' The matrix <i>v</i>.
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i>. If <i>storev</i> = 'C' and <i>side</i> = 'L', <i>ldv</i> ≥ max(1, <i>m</i>); if <i>storev</i> = 'C' and <i>side</i> = 'R', <i>ldv</i> ≥ max(1, <i>n</i>); if <i>storev</i> = 'R', <i>ldv</i> ≥ <i>k</i>.
<i>t</i>	REAL for slarfb DOUBLE PRECISION for dlarfb COMPLEX for clarfb COMPLEX*16 for zlarfb Array, DIMENSION (<i>ldt</i>, <i>k</i>). Contains the triangular <i>k</i>-by-<i>k</i> matrix <i>T</i> in the representation of the block reflector.
<i>LDT</i>	INTEGER. The leading dimension of the array <i>t</i>. <i>ldt</i> ≥ <i>k</i>.
<i>c</i>	REAL for slarfb DOUBLE PRECISION for dlarfb COMPLEX for clarfb COMPLEX*16 for zlarfb Array, DIMENSION (<i>ldc</i>, <i>n</i>). On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.

ldc INTEGER. The leading dimension of the array *c*.
 $ldc \geq \max(1, m)$.

work REAL for *slarfb*
 DOUBLE PRECISION for *dlarfb*
 COMPLEX for *clarfb*
 COMPLEX*16 for *zlarfb*
 Workspace array, DIMENSION (*ldwork*, *k*).

ldwork INTEGER. The leading dimension of the array *work*.
 If *side* = 'L', $ldwork \geq \max(1, n)$;
 if *side* = 'R', $ldwork \geq \max(1, m)$.

Output Parameters

c On exit, *c* is overwritten by H^*C , or H'^*C , or C^*H , or C^*H' .

?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call slarfg( n, alpha, x, incx, tau )
call dlarfg( n, alpha, x, incx, tau )
call clarfg( n, alpha, x, incx, tau )
call zlarfg( n, alpha, x, incx, tau )
```

Description

The routine ?larfg generates a real/complex elementary reflector H of order n , such that

$$H'^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H'^*H = I,$$

where α and β are scalars (with β real for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v' \end{bmatrix}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that for `clarfg/zlarfg`, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$ (for complex flavors).

Input Parameters

n	INTEGER. The order of the elementary reflector.
α	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> COMPLEX*16 for <code>zlarfg</code> On entry, the value α .
x	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> COMPLEX*16 for <code>zlarfg</code> Array, DIMENSION $(1+(n-2)*\text{abs}(\text{incx}))$. On entry, the vector x .
incx	INTEGER. The increment between elements of x . $\text{incx} > 0$.

Output Parameters

α	On exit, it is overwritten with the value β .
x	On exit, it is overwritten with the vector v .
τ	REAL for <code>slarfg</code> DOUBLE PRECISION for <code>dlarfg</code> COMPLEX for <code>clarfg</code> COMPLEX*16 for <code>zlarfg</code> The value τ .

?larft

Forms the triangular factor T of a block reflector H
 $= I - V^* T^* V^H$.

Syntax

```
call slarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call clarft( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlarft( direct, storev, n, k, v, ldv, tau, t, ldt )
```

Description

The routine ?larft forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If $direct = 'F'$, $H = H(1) * H(2) * \dots * H(k)$ and T is upper triangular;

If $direct = 'B'$, $H = H(k) * \dots * H(2) * H(1)$ and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array v , and $H = I - V^* T^* V^H$.

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array v , and $H = I - V^H T^* V$.

Input Parameters

<i>direct</i>	CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): = 'C': column-wise = 'R': row-wise.
<i>n</i>	INTEGER. The order of the block reflector H . $n \geq 0$.

<i>k</i>	INTEGER. The order of the triangular factor <i>T</i> (equal to the number of elementary reflectors). $k \geq 1$.
<i>v</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft COMPLEX*16 for zlarft Array, DIMENSION (<i>ldv</i> , <i>k</i>) if <i>storev</i> = 'C' or (<i>ldv</i> , <i>n</i>) if <i>storev</i> = 'R'. The matrix <i>v</i> .
<i>ldv</i>	INTEGER. The leading dimension of the array <i>v</i> . If <i>storev</i> = 'C', $ldv \geq \max(1, n)$; if <i>storev</i> = 'R', $ldv \geq k$.
<i>tau</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft COMPLEX*16 for zlarft Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$.
<i>ldt</i>	INTEGER. The leading dimension of the output array <i>t</i> . $ldt \geq k$.

Output Parameters

<i>t</i>	REAL for slarft DOUBLE PRECISION for dlarft COMPLEX for clarft COMPLEX*16 for zlarft Array, DIMENSION (<i>ldt</i> , <i>k</i>). The <i>k</i> -by- <i>k</i> triangular factor <i>T</i> of the block reflector. If <i>direct</i> = 'F', <i>T</i> is upper triangular; if <i>direct</i> = 'B', <i>T</i> is lower triangular. The rest of the array is not used.
<i>v</i>	The matrix <i>v</i> .

Application Notes

The shape of the matrix v and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C': *direct* = 'F' and *storev* = 'R':

$$\begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

$$\begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

direct = 'B' and *storev* = 'C': *direct* = 'B' and *storev* = 'R':

$$\begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$

$$\begin{bmatrix} v_1 & v_1 & 1 & & \\ v_2 & v_2 & v_2 & 1 & \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

?larfx

Applies an elementary reflector to a general rectangular matrix, with loop unrolling when the reflector has order less than or equal to 10.

Syntax

```
call slarfx( side, m, n, v, tau, c, ldc, work )
call dlarfx( side, m, n, v, tau, c, ldc, work )
call clarfx( side, m, n, v, tau, c, ldc, work )
call zlarfx( side, m, n, v, tau, c, ldc, work )
```

Description

The routine ?larfx applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right.

H is represented in the form

$H = I - \tau v v'$, where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then H is taken to be the unit matrix

Input Parameters

<i>side</i>	CHARACTER*1. If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H .
<i>m</i>	INTEGER. The number of rows of the matrix C .
<i>n</i>	INTEGER. The number of columns of the matrix C .
<i>v</i>	REAL for slarfx DOUBLE PRECISION for dlarfx COMPLEX for clarfx COMPLEX*16 for zlarfx Array, DIMENSION (<i>m</i>) if <i>side</i> = 'L' or (<i>n</i>) if <i>side</i> = 'R'. The vector v in the representation of H .
<i>tau</i>	REAL for slarfx

	DOUBLE PRECISION for dlarfx
	COMPLEX for clarfx
	COMPLEX*16 for zlarfx
	The value <i>tau</i> in the representation of <i>H</i> .
<i>c</i>	REAL for slarfx
	DOUBLE PRECISION for dlarfx
	COMPLEX for clarfx
	COMPLEX*16 for zlarfx
	Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>C</i> .
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . <i>lda</i> ≥ (1, <i>m</i>).
<i>work</i>	REAL for slarfx
	DOUBLE PRECISION for dlarfx
	COMPLEX for clarfx
	COMPLEX*16 for zlarfx
	Workspace array, DIMENSION
	(<i>n</i>) if <i>side</i> = 'L' or
	(<i>m</i>) if <i>side</i> = 'R'.
	<i>work</i> is not referenced if <i>H</i> has order < 11.

Output Parameters

<i>c</i>	On exit, <i>C</i> is overwritten by the matrix H^*C if <i>side</i> = 'L', or C^*H if <i>side</i> = 'R'.

?largv

Generates a vector of plane rotations with real cosines and real/complex sines.

Syntax

```
call slargv( n, x, incx, y, incy, c, incc )
call dlargv( n, x, incx, y, incy, c, incc )
call clargv( n, x, incx, y, incy, c, incc )
call zlargv( n, x, incx, y, incy, c, incc )
```

Description

The routine generates a vector of real/complex plane rotations with real cosines, determined by elements of the real/complex vectors x and y .

For slargv/dlargv:

$$\begin{bmatrix} c(i) & s(i) \\ -s(i) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} a_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

For clargv/zlargv:

$$\begin{bmatrix} c(i) & s(i) \\ -\text{conjg}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} r_i \\ 0 \end{bmatrix}, \text{ for } i = 1, 2, \dots, n$$

where $c(i)^2 + \text{abs}(s(i))^2 = 1$ and the following conventions are used (these are the same as in clartg/zlartg but differ from the BLAS Level 1 routine crotg/zrotg):

If $y_i = 0$, then $c(i) = 1$ and $s(i) = 0$;

If $x_i = 0$, then $c(i) = 0$ and $s(i)$ is chosen so that r_i is real.

Input Parameters

n	INTEGER. The number of plane rotations to be generated.
x, y	REAL for slargv DOUBLE PRECISION for dlargv COMPLEX for clargv COMPLEX*16 for zlargv Arrays, DIMENSION $(1+(n-1)*incx)$ and $(1+(n-1)*incy)$, respectively. On entry, the vectors x and y .
$incx$	INTEGER. The increment between elements of x . $incx > 0$.
$incy$	INTEGER. The increment between elements of y . $incy > 0$.

incc INTEGER. The increment between elements of the output array *c*. *incc* > 0.

Output Parameters

x On exit, $x(i)$ is overwritten by a_i (for real flavors), or by r_i (for complex flavors), for $i = 1, \dots, n$.

y On exit, the sines $s(i)$ of the plane rotations.

c REAL for slargv/clargv
DOUBLE PRECISION for dlargv/zlargv
Array, DIMENSION $(1+(n-1)*incc)$. The cosines of the plane rotations.

?larnv

Returns a vector of random numbers from a uniform or normal distribution.

Syntax

```
call slarnv( idist, iseed, n, x )
call dlarnv( idist, iseed, n, x )
call clarnv( idist, iseed, n, x )
call zlarnv( idist, iseed, n, x )
```

Description

The routine ?larnv returns a vector of n random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine ?laruv to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

Input Parameters

idist INTEGER. Specifies the distribution of the random numbers:
for slarnv and dlarnv:
= 1: uniform (0,1)
= 2: uniform (-1,1)

= 3: normal (0,1).
for `clarndv` and `zlarndv`:
= 1: real and imaginary parts each uniform (0,1)
= 2: real and imaginary parts each uniform (-1,1)
= 3: real and imaginary parts each normal (0,1)
= 4: uniformly distributed on the disc $\text{abs}(z) < 1$
= 5: uniformly distributed on the circle $\text{abs}(z) = 1$

iseed INTEGER. Array, DIMENSION (4).
On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and *iseed*(4) must be odd.

n INTEGER. The number of random numbers to be generated.

Output Parameters

x REAL for `slarndv`
DOUBLE PRECISION for `dlarndv`
COMPLEX for `clarndv`
COMPLEX*16 for `zlarndv`
Array, DIMENSION (*n*). The generated random numbers.

iseed On exit, the seed is updated.

?larra

Computes the splitting points with the specified threshold.

Syntax

```
call slarra( n, d, e, e2, spltol, tnrm, nsplit, isplit, info )
call dlarra( n, d, e, e2, spltol, tnrm, nsplit, isplit, info )
```

Description

This routine computes the splitting points with the specified threshold and sets any "small" off-diagonal elements to zero.

Input Parameters

n INTEGER. The order of the matrix ($n > 1$).

<i>d</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .
<i>e</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (<i>n</i>). First (<i>n</i> -1) entries contain the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e</i> (<i>n</i>) need not be set.
<i>e2</i>	REAL for slarra DOUBLE PRECISION for dlarra Array, DIMENSION (<i>n</i>). First (<i>n</i> -1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix <i>T</i> ; <i>e2</i> (<i>n</i>) need not be set.
<i>spltol</i>	REAL for slarra DOUBLE PRECISION for dlarra The threshold for splitting. Two criteria can be used: <i>spltol</i> <0 : criterion based on absolute off-diagonal value; <i>spltol</i> >0 : criterion that preserves relative accuracy.
<i>tnrm</i>	REAL for slarra DOUBLE PRECISION for dlarra The norm of the matrix.

Output Parameters

<i>e</i>	On exit, the entries <i>e</i> (<i>isplit</i> (<i>i</i>)), $1 \leq i \leq nsplit$, are set to zero, the other entries of <i>e</i> are untouched.
<i>e2</i>	On exit, the entries <i>e2</i> (<i>isplit</i> (<i>i</i>)), $1 \leq i \leq nsplit$, are set to zero.
<i>nsplit</i>	INTEGER. The number of blocks the matrix <i>T</i> splits into. $1 \leq nsplit \leq n$
<i>isplit</i>	INTEGER. Array, DIMENSION (<i>n</i>).

The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit(1)$, the second of rows/columns $isplit(1)+1$ through $isplit(2)$, and so on, and the $nsplit$ -th consists of rows/columns $isplit(nsplit-1)+1$ through $isplit(nsplit)=n$.

info

INTEGER.

= 0: successful exit.

?larrb

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

call slarrb(*n*, *d*, *lld*, *ifirst*, *ilast*, *rtol1*, *rtol2*, *offset*, *w*, *wgap*, *werr*,
work, *iwork*, *pivmin*, *spdiam*, *twist*, *info*)

call dlarrb(*n*, *d*, *lld*, *ifirst*, *ilast*, *rtol1*, *rtol2*, *offset*, *w*, *wgap*, *werr*,
work, *iwork*, *pivmin*, *spdiam*, *twist*, *info*)

Description

Given the relatively robust representation (RRR) $L^*D^*L^T$, the routine does "limited" bisection to refine the eigenvalues of $L^*D^*L^T$, $w(ifirst-offset)$ through $w(ilast-offset)$, to more accuracy. Initial guesses for these eigenvalues are input in w . The corresponding estimate of the error in these guesses and their gaps are input in $werr$ and $wgap$, respectively. During bisection, intervals $[left, right]$ are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

n INTEGER. The order of the matrix.

d REAL for slarrb
DOUBLE PRECISION for dlarrb
Array, DIMENSION (*n*). The *n* diagonal elements of the diagonal matrix D .

lld REAL for slarrb
DOUBLE PRECISION for dlarrb
Array, DIMENSION (*n-1*).

	The $n-1$ elements $L_i * L_i * D_i$.
<i>ifirst</i>	INTEGER. The index of the first eigenvalue to be computed.
<i>ilast</i>	INTEGER. The index of the last eigenvalue to be computed.
<i>rtol1, rtol2</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Tolerance for the convergence of the bisection intervals. An interval [<i>left</i> , <i>right</i>] has converged if $\text{RIGHT-LEFT.LT.MAX}(\text{rtol1} * \text{gap}, \text{rtol2} * \max(\text{left} , \text{right}))$, where <i>gap</i> is the (estimated) distance to the nearest eigenvalue.
<i>offset</i>	INTEGER. Offset for the arrays <i>w</i> , <i>wgap</i> and <i>werr</i> , that is, the <i>ifirst</i> - <i>offset</i> through <i>ilast</i> - <i>offset</i> elements of these arrays are to be used.
<i>w</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n</i>). On input, <i>w</i> (<i>ifirst</i> - <i>offset</i>) through <i>w</i> (<i>ilast</i> - <i>offset</i>) are estimates of the eigenvalues of $L * D * L^T$ indexed <i>ifirst</i> through <i>ilast</i> .
<i>wgap</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n</i> -1). The estimated gaps between consecutive eigenvalues of $L * D * L^T$, that is, <i>wgap</i> (<i>i</i> - <i>offset</i>) is the gap between eigenvalues <i>i</i> and <i>i</i> +1. Note that if <i>IFIRST</i> .EQ. <i>ILAST</i> then <i>wgap</i> (<i>ifirst</i> - <i>offset</i>) must be set to 0.
<i>werr</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Array, DIMENSION (<i>n</i>). On input, <i>werr</i> (<i>ifirst</i> - <i>offset</i>) through <i>werr</i> (<i>ilast</i> - <i>offset</i>) are the errors in the estimates of the corresponding elements in <i>w</i> .
<i>work</i>	REAL for slarrb DOUBLE PRECISION for dlarrb Workspace array, DIMENSION (2* <i>n</i>).
<i>pivmin</i>	REAL for slarrb DOUBLE PRECISION for dlarrb The minimum pivot in the Sturm sequence.

<i>spdiam</i>	REAL for slarrb DOUBLE PRECISION for dlarrb The spectral diameter of the matrix.
<i>twist</i>	INTEGER. The twist index for the twisted factorization that is used for the negcount. $twist = n: \text{ Compute negcount from } L^*D^*L^T - \lambda i$ $= L_+^* D_+^* L_+^T$ $twist = n: \text{ Compute negcount from } L^*D^*L^T - \lambda i$ $= U_-^* D_-^* U_-^T$ $twist = n: \text{ Compute negcount from } L^*D^*L^T - \lambda i$ $= N_r^* D_r^* N_r$
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (2*n).

Output Parameters

<i>w</i>	On output, the estimates of the eigenvalues are “refined”.
<i>wgap</i>	On output, the gaps are refined.
<i>werr</i>	On output, “refined” errors in the estimates of <i>w</i> .
<i>info</i>	INTEGER. Error flag.

slarrc

Computes the number of eigenvalues of the symmetric tridiagonal matrix.

Syntax

```
call slarrc( jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info )
call dlarrc( jobt, n, vl, vu, d, e, pivmin, eigcnt, lcnt, rcnt, info )
```

Description

This routine finds the number of eigenvalues of the symmetric tridiagonal matrix *T* or of its factorization $L^*D^*L^T$ in the specified interval.

Input Parameters

<i>jobt</i>	CHARACTER*1. = 'T': computes Sturm count for matrix T . = 'L': computes Sturm count for matrix $L^*D^*L^T$.
<i>n</i>	INTEGER. The order of the matrix. ($n > 1$).
<i>vl,vu</i>	REAL for slarrc DOUBLE PRECISION for dlarrc The lower and upper bounds for the eigenvalues.
<i>d</i>	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If <i>jobt</i> = 'T': contains the n diagonal elements of the tridiagonal matrix T . If <i>jobt</i> = 'L': contains the n diagonal elements of the diagonal matrix D .
<i>e</i>	REAL for slarrc DOUBLE PRECISION for dlarrc Array, DIMENSION (n). If <i>jobt</i> = 'T': contains the $(n-1)$ offdiagonal elements of the matrix T . If <i>jobt</i> = 'L': contains the $(n-1)$ offdiagonal elements of the matrix L .
<i>pivmin</i>	REAL for slarrc DOUBLE PRECISION for dlarrc The minimum pivot in the Sturm sequence for the matrix T .

Output Parameters

<i>eigcnt</i>	INTEGER. The number of eigenvalues of the symmetric tridiagonal matrix T that are in the half-open interval $(vl, vu]$.
<i>lcnt,rcnt</i>	INTEGER. The left and right negcounts of the interval.
<i>info</i>	INTEGER.

Now it is not used and always is set to 0.

?larrd

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

```
call slarrd( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin,
            nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info )

call dlarrd( range, order, n, vl, vu, il, iu, gers, reltol, d, e, e2, pivmin,
            nsplit, isplit, m, w, werr, wl, wu, iblock, indexw, work, iwork, info )
```

Description

The routine computes the eigenvalues of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from `?stemr`. The user may ask for all eigenvalues, all eigenvalues in the half-open interval $(vl, vu]$, or the il -th through iu -th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. (For more details see [Kahan66]).

Input Parameters

<i>range</i>	CHARACTER. = 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval $(vl, vu]$ will be found. = 'I': ("Index") the il-th through iu-th eigenvalues will be found.
<i>order</i>	CHARACTER. = 'B': ("By block") the eigenvalues will be grouped by split-off block (see <i>iblock</i>, <i>isplit</i> below) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.
<i>n</i>	INTEGER. The order of the tridiagonal matrix T ($n \geq 1$).
<i>vl,vu</i>	REAL for <code>slarrd</code>

DOUBLE PRECISION for dlarrrd
 If *range* = 'V': the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to *vl*, or greater than *vu*, will not be returned.
vl < *vu*.
 If *range* = 'A' or 'I': not referenced.

il,iu INTEGER.
 If *range* = 'I': the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n=0$.
 If *range* = 'A' or 'V': not referenced.

gers REAL for slarrrd
 DOUBLE PRECISION for dlarrrd
 Array, DIMENSION (2*n).
 The n Gerschgorin intervals (the i -th Gerschgorin interval is (*gers*(2*i-1), *gers*(2*i))).

reltol REAL for slarrrd
 DOUBLE PRECISION for dlarrrd
 The minimum relative width of an interval. When an interval is narrower than *reltol* times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least *radix*machine epsilon*.

d REAL for slarrrd
 DOUBLE PRECISION for dlarrrd
 Array, DIMENSION (n).
 Contains n diagonal elements of the tridiagonal matrix T .

e REAL for slarrrd
 DOUBLE PRECISION for dlarrrd
 Array, DIMENSION ($n-1$).
 Contains ($n-1$) off-diagonal elements of the tridiagonal matrix T .

e2 REAL for slarrrd
 DOUBLE PRECISION for dlarrrd
 Array, DIMENSION ($n-1$).

	Contains $(n-1)$ squared off-diagonal elements of the tridiagonal matrix T .
<i>pivmin</i>	REAL for slarrd DOUBLE PRECISION for dlarrrd The minimum pivot in the Sturm sequence for the matrix T .
<i>nsplit</i>	INTEGER. The number of diagonal blocks the matrix T . $1 \leq nsplit \leq n$
<i>isplit</i>	INTEGER. Arrays, DIMENSION (n) . The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), and so on, and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= n . (Only the first <i>nsplit</i> elements actually is used, but since the user cannot know a priori value of <i>nsplit</i> , n words must be reserved for <i>isplit</i> .)
<i>work</i>	REAL for slarrd DOUBLE PRECISION for dlarrrd Workspace array, DIMENSION $(4*n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION $(4*n)$.

Output Parameters

<i>m</i>	INTEGER. The actual number of eigenvalues found. $0 \leq m \leq n$. (See also the description of <i>info</i> =2, 3.)
<i>w</i>	REAL for slarrd DOUBLE PRECISION for dlarrrd Array, DIMENSION (n) .

The first m elements of w contain the eigenvalue approximations. ?laprd computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue j . The eigenvalue approximation is given as the interval midpoint $w(j) = (a_j + b_j) / 2$. The corresponding error is bounded by $werr(j) = \text{abs}(a_j - b_j) / 2$.

werr

REAL for slarrd
DOUBLE PRECISION for dlarrrd
Array, DIMENSION (n).

The error bound on the corresponding eigenvalue approximation in w .

wl, wu

REAL for slarrd
DOUBLE PRECISION for dlarrrd
The interval $(wl, wu]$ contains all the wanted eigenvalues.
If *range* = 'V': then $wl = vl$ and $wu = vu$.
If *range* = 'A': then wl and wu are the global Gerschgorin bounds on the spectrum.
If *range* = 'I': then wl and wu are computed by ?laebz from the index range specified.

iblock

INTEGER.
Array, DIMENSION (n).
At each row/column j where $e(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix.
If $info = 0$, then $iblock(i)$ specifies to which block (from 1 to the number of blocks) the eigenvalue $w(i)$ belongs.
(The routine may use the remaining $n-m$ elements as workspace.)

indexw

INTEGER.
Array, DIMENSION (n).
The indices of the eigenvalues within each block (submatrix); for example, $indexw(i) = j$ and $iblock(i) = k$ imply that the i -th eigenvalue $w(i)$ is the j -th eigenvalue in block k .

info

INTEGER.
= 0: successful exit.
< 0: if $info = -i$, the i -th argument has an illegal value
> 0: some or all of the eigenvalues fail to converge or are not computed:

=1 or 3: bisection fail to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

=2 or 3: `range='I'` only: not all of the eigenvalues `il:iu` are found.

=4: `range='I'`, and the Gershgorin interval initially used is too small. No eigenvalues are computed.

?larre

Given the tridiagonal matrix T , sets small off-diagonal elements to zero and for each unreduced block T_i , finds base representations and eigenvalues.

Syntax

```
call slarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit,
            isplit, m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )

call dlarre( range, n, vl, vu, il, iu, d, e, e2, rtol1, rtol2, spltol, nsplit,
            isplit, m, w, werr, wgap, iblock, indexw, gers, pivmin, work, iwork, info )
```

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , the routine sets any “small” off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block spectrum
- the base representation, $T_i - \sigma_i * I = L_i * D_i * L_i^T$, and
- eigenvalues of each $L_i * D_i * L_i^T$.

The representations and eigenvalues found are then used by `?stemr` to compute the eigenvectors of a symmetric tridiagonal matrix. The accuracy varies depending on whether bisection is used to find a few eigenvalues or the `dqds` algorithm (subroutine `?lasq2`) to compute all and discard any unwanted one. As an added benefit, `?larre` also outputs the n Gerschgorin intervals for the matrices $L_i * D_i * L_i^T$.

Input Parameters

<i>range</i>	CHARACTER. = 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval $(v_l, v_u]$ will be found. = 'I': ("Index") the i_l-th through i_u-th eigenvalues of the entire matrix will be found.
<i>n</i>	INTEGER. The order of the matrix. $n > 0$.
<i>v_l, v_u</i>	REAL for slarre DOUBLE PRECISION for dlarre If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to v_l, or greater than v_u, are not returned. $v_l < v_u$.
<i>i_l, i_u</i>	INTEGER. If <i>range</i>='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq i_l \leq i_u \leq n$.
<i>d</i>	REAL for slarre DOUBLE PRECISION for dlarre Array, DIMENSION (n). The n diagonal elements of the diagonal matrices T.
<i>e</i>	REAL for slarre DOUBLE PRECISION for dlarre Array, DIMENSION (n). The first $(n-1)$ entries contain the subdiagonal elements of the tridiagonal matrix T; $e(n)$ need not be set.
<i>e2</i>	REAL for slarre DOUBLE PRECISION for dlarre Array, DIMENSION (n). The first $(n-1)$ entries contain the squares of the subdiagonal elements of the tridiagonal matrix T; $e2(n)$ need not be set.
<i>rtol1, rtol2</i>	REAL for slarre DOUBLE PRECISION for dlarre

	Parameters for bisection. An interval <code>[LEFT,RIGHT]</code> has converged if <code>RIGHT-LEFT.LT.MAX(rtol1*gap, rtol2*max(LEFT , RIGHT))</code> .
<code>spltol</code>	REAL for <code>slarre</code> DOUBLE PRECISION for <code>dlarre</code> The threshold for splitting.
<code>work</code>	REAL for <code>slarre</code> DOUBLE PRECISION for <code>dlarre</code> Workspace array, DIMENSION <code>(6*n)</code> .
<code>iwork</code>	INTEGER. Workspace array, DIMENSION <code>(5*n)</code> .

Output Parameters

<code>vl, vu</code>	On exit, if <code>range='I'</code> or <code>'A'</code> , contain the bounds on the desired part of the spectrum.
<code>d</code>	On exit, the n diagonal elements of the diagonal matrices D_i .
<code>e</code>	On exit, the subdiagonal elements of the unit bidiagonal matrices L_i . The entries <code>e(isplit(i))</code> , $1 \leq i \leq nsplit$, contain the base points σ_{σ_i} on output.
<code>e2</code>	On exit, the entries <code>e2(isplit(i))</code> , $1 \leq i \leq nsplit$, have been set to zero.
<code>nsplit</code>	INTEGER. The number of blocks T splits into. $1 \leq nsplit \leq n$.
<code>isplit</code>	INTEGER. Array, DIMENSION <code>(n)</code> . The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to <code>isplit(1)</code> , the second of rows/columns <code>isplit(1)+1</code> through <code>isplit(2)</code> , etc., and the <code>nsplit</code> -th consists of rows/columns <code>isplit(nsplit-1)+1</code> through <code>isplit(nsplit)=n</code> .
<code>m</code>	INTEGER. The total number of eigenvalues (of all the $L_i * D_i * L_i^T$) found.
<code>w</code>	REAL for <code>slarre</code> DOUBLE PRECISION for <code>dlarre</code>

Array, DIMENSION (n). The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i * D_i * L_i^T$, are sorted in ascending order. The routine may use the remaining $n-m$ elements as workspace.

werr REAL for slarre
DOUBLE PRECISION for dlarre
Array, DIMENSION (n). The error bound on the corresponding eigenvalue in w .

wgap REAL for slarre
DOUBLE PRECISION for dlarre
Array, DIMENSION (n). The separation from the right neighbor eigenvalue in w . The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block the left gap is stored.

iblock INTEGER. Array, DIMENSION (n).
The indices of the blocks (submatrices) associated with the corresponding eigenvalues in w ; $iblock(i)=1$ if eigenvalue $w(i)$ belongs to the first block from the top, $=2$ if $w(i)$ belongs to the second block, etc.

indexw INTEGER. Array, DIMENSION (n).
The indices of the eigenvalues within each block (submatrix); for example, $indexw(i)=10$ and $iblock(i)=2$ imply that the i -th eigenvalue $w(i)$ is the 10-th eigenvalue in the second block.

gers REAL for slarre
DOUBLE PRECISION for dlarre
Array, DIMENSION ($2*n$). The n Gerschgorin intervals (the i -th Gerschgorin interval is $(gers(2*i-1), gers(2*i))$).

pivmin REAL for slarre
DOUBLE PRECISION for dlarre
The minimum pivot in the Sturm sequence for T .

info INTEGER.
If $info = 0$: successful exit
If $info > 0$: A problem occurred in ?larre. If $info = 5$, the Rayleigh Quotient Iteration failed to converge to full accuracy.

If $info < 0$: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter $info$ for further information is required.

- If $info = -1$, there is a problem in `?larrrd`
- If $info = -2$, no base representation could be found in `maxtry` iterations. Increasing `maxtry` and recompilation might be a remedy.
- If $info = -3$, there is a problem in `?larrrb` when computing the refined root representation for `?lasq2`.
- If $info = -4$, there is a problem in `?larrrb` when performing bisection on the desired part of the spectrum.
- If $info = -5$, there is a problem in `?lasq2`.
- If $info = -6$, there is a problem in `?lasq2`.

?larrrf

Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.

Syntax

```
call slarrrf( n, d, l, ld, clstrt, clend, w, wgap, werr, spdiam, clgapl, clgapr,
             pivmin, sigma, dplus, lplus, work, info )
```

```
call dlarrrf( n, d, l, ld, clstrt, clend, w, wgap, werr, spdiam, clgapl, clgapr,
             pivmin, sigma, dplus, lplus, work, info )
```

Description

Given the initial representation $L * D * L^T$ and its cluster of close eigenvalues (in a relative measure), $w(clstrt), w(clstrt+1), \dots w(clend)$, the routine `?larrrf` finds a new relatively robust representation

$$L * D * L^T - \sigma_i * I = L(+) * D(+) * L(+)^T$$

such that at least one of the eigenvalues of $L(+) * D(+) * L(+)^T$ is relatively isolated.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix (subblock, if the matrix is splitted).
<i>d</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>l</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> .
<i>ld</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (<i>n</i> -1). The <i>n</i> -1 elements $L_i * D_i$.
<i>clstrt</i>	INTEGER. The index of the first eigenvalue in the cluster.
<i>clend</i>	INTEGER. The index of the last eigenvalue in the cluster.
<i>w</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION $\geq (clend - clstrt + 1)$. The eigenvalue approximations of $L * D * L^T$ in ascending order. $w(clstrt)$ through $w(clend)$ form the cluster of relatively close eigenvalues.
<i>wgap</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION $\geq (clend - clstrt + 1)$. The separation from the right neighbor eigenvalue in <i>w</i> .
<i>werr</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION $\geq (clend - clstrt + 1)$. On input, <i>werr</i> contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in <i>w</i> .
<i>spdiam</i>	REAL for slarrf DOUBLE PRECISION for dlarrf

	Estimate of the spectral diameter obtained from the Gerschgorin intervals.
<i>clgapl, clgapr</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Absolute gap on each end of the cluster. Set by the calling routine to protect against shifts too close to eigenvalues outside the cluster.
<i>pivmin</i>	REAL for slarrf DOUBLE PRECISION for dlarrf The minimum pivot allowed in the Sturm sequence.
<i>work</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Workspace array, DIMENSION (2*n).

Output Parameters

<i>wgap</i>	On output, the gaps are refined.
<i>sigma</i>	REAL for slarrf DOUBLE PRECISION for dlarrf The shift used to form $L(+) * D^*(+) * L(+)^T$.
<i>dplus</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (n). The n diagonal elements of the diagonal matrix $D(+)$.
<i>lplus</i>	REAL for slarrf DOUBLE PRECISION for dlarrf Array, DIMENSION (n). The first (n-1) elements of <i>lplus</i> contain the subdiagonal elements of the unit bidiagonal matrix $L(+)$.

zlarrj

Performs refinement of the initial estimates of the eigenvalues of the matrix T .

Syntax

```
call slarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork,
            pivmin, spdiam, info )
```

```
call dlarrj( n, d, e2, ifirst, ilast, rtol, offset, w, werr, work, iwork,
            pivmin, spdiam, info )
```

Description

Given the initial eigenvalue approximations of T , this routine does bisection to refine the eigenvalues of T , $w(\text{ifirst}-\text{offset})$ through $w(\text{ilast}-\text{offset})$, to more accuracy. Initial guesses for these eigenvalues are input in w , the corresponding estimate of the error in these guesses in $werr$. During bisection, intervals $[a,b]$ are maintained by storing their mid-points and semi-widths in the arrays w and $werr$ respectively.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T .
<i>d</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
<i>e2</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION ($n-1$). Contains ($n-1$) squared sub-diagonal elements of the T .
<i>ifirst</i>	INTEGER. The index of the first eigenvalue to be computed.
<i>ilast</i>	INTEGER. The index of the last eigenvalue to be computed.
<i>rtol</i>	REAL for slarrj DOUBLE PRECISION for dlarrj

	Tolerance for the convergence of the bisection intervals. An interval $[a, b]$ is considered to be converged if $(b-a) \leq rtol * \max(a , b)$.
<i>offset</i>	INTEGER. Offset for the arrays <i>w</i> and <i>werr</i> , that is the <i>ifirst-offset</i> through <i>ilast-offset</i> elements of these arrays are to be used.
<i>w</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION (<i>n</i>). On input, <i>w(ifirst-offset)</i> through <i>w(ilast-offset)</i> are estimates of the eigenvalues of L^*D*L^T indexed <i>ifirst</i> through <i>ilast</i> .
<i>werr</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Array, DIMENSION (<i>n</i>). On input, <i>werr(ifirst-offset)</i> through <i>werr(ilast-offset)</i> are the errors in the estimates of the corresponding elements in <i>w</i> .
<i>work</i>	REAL for slarrj DOUBLE PRECISION for dlarrj Workspace array, DIMENSION ($2*n$).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION ($2*n$).
<i>pivmin</i>	REAL for slarrj DOUBLE PRECISION for dlarrj The minimum pivot in the Sturm sequence for the matrix <i>T</i> .
<i>spdiam</i>	REAL for slarrj DOUBLE PRECISION for dlarrj The spectral diameter of the matrix <i>T</i> .

Output Parameters

<i>w</i>	On exit, contains the refined estimates of the eigenvalues.

<code>werr</code>	On exit, contains the refined errors in the estimates of the corresponding elements in w .
<code>info</code>	INTEGER. Now it is not used and always is set to 0.

?larrk

Computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy.

Syntax

```
call slarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
call dlarrk( n, iw, gl, gu, d, e2, pivmin, reltol, w, werr, info )
```

Description

The routine computes one eigenvalue of a symmetric tridiagonal matrix T to suitable accuracy. This is an auxiliary code to be called from `?stemr`.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $(\text{overflow}^{1/2} * \text{underflow}^{1/4})$ in absolute value, and for greatest accuracy, it should not be much smaller than that. (For more details see [Kahan66].)

Input Parameters

n	INTEGER. The order of the matrix T . ($n \geq 1$).
iw	INTEGER. The index of the eigenvalue to be returned.
gl, gu	REAL for <code>slarrk</code> DOUBLE PRECISION for <code>dlarrk</code> An upper and a lower bound on the eigenvalue.
d	REAL for <code>slarrk</code> DOUBLE PRECISION for <code>dlarrk</code> Array, DIMENSION (n). Contains n diagonal elements of the matrix T .
$e2$	REAL for <code>slarrk</code> DOUBLE PRECISION for <code>dlarrk</code> Array, DIMENSION ($n-1$).

<i>pivmin</i>	Contains $(n-1)$ squared off-diagonal elements of the T. REAL for slarrk DOUBLE PRECISION for dlarrk The minimum pivot in the Sturm sequence for the matrix T.
<i>reltol</i>	REAL for slarrk DOUBLE PRECISION for dlarrk The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, that is converged. Note: this should always be at least <i>radix*machine epsilon</i>.

Output Parameters

<i>w</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Contains the eigenvalue approximation.
<i>werr</i>	REAL for slarrk DOUBLE PRECISION for dlarrk Contains the error bound on the corresponding eigenvalue approximation in w.
<i>info</i>	INTEGER. = 0: Eigenvalue converges = -1: Eigenvalue does not converge

?larr

Performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Syntax

```
call slarr( n, d, e, info )
call dlarr( n, d, e, info )
```

Description

The routine performs tests to decide whether the symmetric tridiagonal matrix T warrants expensive computations which guarantee high relative accuracy in the eigenvalues.

Input Parameters

n INTEGER. The order of the matrix T . ($n > 0$).

d REAL for slarrv
DOUBLE PRECISION for dlarrv
Array, DIMENSION (n).
Contains n diagonal elements of the matrix T .

e REAL for slarrv
DOUBLE PRECISION for dlarrv
Array, DIMENSION (n).
The first $(n-1)$ entries contain sub-diagonal elements of the tridiagonal matrix T ; $e(n)$ is set to 0.

Output Parameters

$info$ INTEGER.
= 0: the matrix warrants computations preserving relative accuracy (default value).
= -1: the matrix warrants computations guaranteeing only absolute accuracy.

?larrv

Computes the eigenvectors of the tridiagonal matrix $T = L^*D^*L^T$ given L , D and the eigenvalues of $L^*D^*L^T$.

Syntax

```
call slarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )

call dlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )

call clarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )

call zlarrv( n, vl, vu, d, l, pivmin, isplit, m, dol, dou, minrgp, rtol1,
            rtol2, w, werr, wgap, iblock, indexw, gers, z, ldz, isuppz, work, iwork, info
            )
```

Description

The routine ?larrv computes the eigenvectors of the tridiagonal matrix $T = L^*D^*L^T$ given L , D and approximations to the eigenvalues of $L^*D^*L^T$.

The input eigenvalues should have been computed by slarre for real flavors (slarrv/clarrv) and by dlarre for double precision flavors (dlarrv/zlarrv).

Input Parameters

n	INTEGER. The order of the matrix. $n \geq 0$.
vl, vu	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Lower and upper bounds respectively of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range.
d	REAL for slarrv/clarrv

DOUBLE PRECISION for dlarrv/zlarrv
 Array, DIMENSION (n). On entry, the n diagonal elements of the diagonal matrix D .

l REAL for slarrv/clarrv
 DOUBLE PRECISION for dlarrv/zlarrv
 Array, DIMENSION (n).
 On entry, the $(n-1)$ subdiagonal elements of the unit bidiagonal matrix L are contained in elements 1 to $n-1$ of L if the matrix is not splitted. At the end of each block the corresponding shift is stored as given by slarre for real flavors and by dlarre for double precision flavors.

pivmin REAL for slarrv/clarrv
 DOUBLE PRECISION for dlarrv/zlarrv
 The minimum pivot allowed in the Sturm sequence.

isplit INTEGER. Array, DIMENSION (n).
 The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to isplit(1), the second of rows/columns isplit(1)+1 through isplit(2), etc.

m INTEGER. The total number of eigenvalues found.
 $0 \leq m \leq n$. If range = 'A', $m = n$, and if range = 'I', $m = iu - il + 1$.

dol, dou INTEGER.
 If you want to compute only selected eigenvectors from all the eigenvalues supplied, specify an index range dol:dou. Or else apply the setting dol=1, dou=m. Note that dol and dou refer to the order in which the eigenvalues are stored in w .
 If you want to compute only selected eigenpairs, then the columns dol-1 to dou+1 of the eigenvector space Z contain the computed eigenvectors. All other columns of Z are set to zero.

minrgp, rtol1, rtol2 REAL for slarrv/clarrv
 DOUBLE PRECISION for dlarrv/zlarrv
 Parameters for bisection. An interval [LEFT,RIGHT] has converged if RIGHT-LEFT.LT.MAX(rtol1*gap, rtol2*max(|LEFT|,|RIGHT|)).

<i>w</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). The first <i>m</i> elements of <i>w</i> contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block (the output array <i>w</i> from ?larre is expected here). These eigenvalues are set with respect to the shift of the corresponding root representation for their block.
<i>werr</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). The first <i>m</i> elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in <i>w</i>.
<i>wgap</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (<i>n</i>). The separation from the right neighbor eigenvalue in <i>w</i>.
<i>iblock</i>	INTEGER. Array, DIMENSION (<i>n</i>). The indices of the blocks (submatrices) associated with the corresponding eigenvalues in <i>w</i>; <i>iblock</i>(<i>i</i>)=1 if eigenvalue <i>w</i>(<i>i</i>) belongs to the first block from the top, =2 if <i>w</i>(<i>i</i>) belongs to the second block, etc.
<i>indexw</i>	INTEGER. Array, DIMENSION (<i>n</i>). The indices of the eigenvalues within each block (submatrix); for example, <i>indexw</i>(<i>i</i>)= 10 and <i>iblock</i>(<i>i</i>)=2 imply that the <i>i</i>-th eigenvalue <i>w</i>(<i>i</i>) is the 10-th eigenvalue in the second block.
<i>gers</i>	REAL for slarrv/clarrv DOUBLE PRECISION for dlarrv/zlarrv Array, DIMENSION (2*<i>n</i>). The <i>n</i> Gerschgorin intervals (the <i>i</i>-th Gerschgorin interval is (<i>gers</i>(2*<i>i</i>-1), <i>gers</i>(2*<i>i</i>)). The Gerschgorin intervals should be computed from the original unshifted matrix.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i>. <i>ldz</i> ≥ 1, and if <i>jobz</i> = 'V', <i>ldz</i> ≥ max(1, <i>n</i>).

work REAL for slarrv/clarrv
DOUBLE PRECISION for dlarrv/zlarrv
Workspace array, DIMENSION (12*n).

iwork INTEGER.
Workspace array, DIMENSION (7*n).

Output Parameters

d On exit, *d* may be overwritten.

l On exit, *l* is overwritten.

w On exit, *w* holds the eigenvalues of the unshifted matrix.

werr On exit, *werr* contains refined values of its input approximations.

wgap On exit, *wgap* contains refined values of its input approximations. Very small gaps are changed.

z REAL for slarrv
DOUBLE PRECISION for dlarrv
COMPLEX for clarrv
COMPLEX*16 for zlarrv
Array, DIMENSION (ldz, max(1,m)).
If *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *T* corresponding to the input eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).

NOTE. The user must ensure that at least max(1,m) columns are supplied in the array *z*.

isuppz INTEGER .
Array, DIMENSION (2*max(1,m)) . The support of the eigenvectors in *z*, that is, the indices indicating the nonzero elements in *z*. The *i*-th eigenvector is nonzero only in elements *isuppz*(2*i*-1) through *isuppz*(2*i*).

info INTEGER.
If *info* = 0: successful exit

If *info* > 0: A problem occurred in ?larrv. If *info* = 5, the Rayleigh Quotient Iteration failed to converge to full accuracy.

If *info* < 0: One of the called subroutines signaled an internal problem. Inspection of the corresponding parameter *info* for further information is required.

- If *info* = -1, there is a problem in ?larrrb when refining a child eigenvalue;
- If *info* = -2, there is a problem in ?larrrf when computing the relatively robust representation (RRR) of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter *minrgp* smaller and recompile. However, as the orthogonality of the computed vectors is proportional to $1/\text{minrgp}$, you should be aware that you might be trading in precision when you decrease *minrgp*.
- If *info* = -3, there is a problem in ?larrrb when refining a single eigenvalue after the Rayleigh correction was rejected.

?lartg

Generates a plane rotation with real cosine and real/complex sine.

Syntax

```
call slartg( f, g, cs, sn, r )
```

```
call dlartg( f, g, cs, sn, r )
```

```
call clartg( f, g, cs, sn, r )
```

```
call zlartg( f, g, cs, sn, r )
```

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -\text{conjg}(sn) & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + |sn|^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine `?rotg`, except for the following differences.

For `slartg/dlartg`:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$ and $g \neq 0$, then $cs=0$ and $sn=1$ without doing any floating point operations (saves work in `?bdsqr` when there are zeros on the diagonal);

If f exceeds g in magnitude, cs will be positive.

For `clartg/zlartg`:

f and g are unchanged on return;

If $g=0$, then $cs=1$ and $sn=0$;

If $f=0$, then $cs=0$ and sn is chosen so that r is real.

Input Parameters

f, g REAL for `slartg`
 DOUBLE PRECISION for `dlartg`
 COMPLEX for `clartg`
 COMPLEX*16 for `zlartg`
 The first and second component of vector to be rotated.

Output Parameters

cs REAL for `slartg/clartg`
 DOUBLE PRECISION for `dlartg/zlartg`
 The cosine of the rotation.

sn REAL for `slartg`
 DOUBLE PRECISION for `dlartg`
 COMPLEX for `clartg`

	COMPLEX*16 for zlarg
	The sine of the rotation.
r	REAL for slarg
	DOUBLE PRECISION for dlarg
	COMPLEX for clarg
	COMPLEX*16 for zlarg
	The nonzero component of the rotated vector.

?larg

Applies a vector of plane rotations with real cosines and real/complex sines to the elements of a pair of vectors.

Syntax

```
call slarg( n, x, incx, y, incy, c, s, incc )
call dlarg( n, x, incx, y, incy, c, s, incc )
call clarg( n, x, incx, y, incy, c, s, incc )
call zlarg( n, x, incx, y, incy, c, s, incc )
```

Description

The routine applies a vector of real/complex plane rotations with real cosines to elements of the real/complex vectors x and y . For $i = 1, 2, \dots, n$

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} := \begin{bmatrix} c(i) & s(i) \\ -\text{conjg}(s(i)) & c(i) \end{bmatrix} \begin{bmatrix} x_i \\ y_i \end{bmatrix}$$

Input Parameters

n	INTEGER. The number of plane rotations to be applied.
x, y	REAL for slarg DOUBLE PRECISION for dlarg COMPLEX for clarg COMPLEX*16 for zlarg

Arrays, DIMENSION $(1+(n-1)*incx)$ and $(1+(n-1)*incy)$, respectively. The input vectors x and y .

incx INTEGER. The increment between elements of x . $incx > 0$.

incy INTEGER. The increment between elements of y . $incy > 0$.

c REAL for slartv/clartv
DOUBLE PRECISION for dlartv/zlartv
Array, DIMENSION $(1+(n-1)*incc)$.
The cosines of the plane rotations.

s REAL for slartv
DOUBLE PRECISION for dlartv
COMPLEX for clartv
COMPLEX*16 for zlartv
Array, DIMENSION $(1+(n-1)*incc)$.
The sines of the plane rotations.

incc INTEGER. The increment between elements of c and s . $incc > 0$.

Output Parameters

x, y The rotated vectors x and y .

?laruv

Returns a vector of n random real numbers from a uniform distribution.

Syntax

```
call slaruv( iseed, n, x )
call dlaruv( iseed, n, x )
```

Description

The routine ?laruv returns a vector of n random real numbers from a uniform (0,1) distribution ($n \leq 128$).

This is an auxiliary routine called by ?larnv.

Input Parameters

<i>iseed</i>	INTEGER. Array, DIMENSION (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd.
<i>n</i>	INTEGER. The number of random numbers to be generated. $n \leq 128$.

Output Parameters

<i>x</i>	REAL for slaruv DOUBLE PRECISION for dlaruv Array, DIMENSION (<i>n</i>). The generated random numbers.
<i>seed</i>	On exit, the seed is updated.

?larz

Applies an elementary reflector (as returned by ?tzzrzf) to a general matrix.

Syntax

```
call slarz( side, m, n, l, v, incv, tau, c, ldc, work )
call dlarz( side, m, n, l, v, incv, tau, c, ldc, work )
call clarz( side, m, n, l, v, incv, tau, c, ldc, work )
call zlarz( side, m, n, l, v, incv, tau, c, ldc, work )
```

Description

The routine ?larz applies a real/complex elementary reflector H to a real/complex m -by- n matrix C , from either the left or the right. H is represented in the form

$$H = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then H is taken to be the unit matrix.

For complex flavors, to apply H^H (the conjugate transpose of H), supply `conjg( $\tau$ )` instead of τ .

H is a product of k elementary reflectors as returned by ?tzzrzf.

Input Parameters

side CHARACTER*1.
 If *side* = 'L': form H^*C
 If *side* = 'R': form C^*H

m INTEGER. The number of rows of the matrix C .

n INTEGER. The number of columns of the matrix C .

l INTEGER. The number of entries of the vector v containing the meaningful part of the Householder vectors.
 If *side* = 'L', $m \geq L \geq 0$,
 if *side* = 'R', $n \geq L \geq 0$.

v REAL for slarz
 DOUBLE PRECISION for dlarz
 COMPLEX for clarz
 COMPLEX*16 for zlarz
 Array, DIMENSION (1+(*l*-1)*abs(*incv*)).
 The vector v in the representation of H as returned by ?tzzrzf.
v is not used if $\tau = 0$.

incv INTEGER. The increment between elements of v .
incv $\neq 0$.

tau REAL for slarz
 DOUBLE PRECISION for dlarz
 COMPLEX for clarz
 COMPLEX*16 for zlarz
 The value τ in the representation of H .

c REAL for slarz
 DOUBLE PRECISION for dlarz
 COMPLEX for clarz
 COMPLEX*16 for zlarz
 Array, DIMENSION (*ldc*,*n*).
 On entry, the m -by- n matrix C .

ldc INTEGER. The leading dimension of the array c .
ldc $\geq \max(1, m)$.

work REAL for slarz
 DOUBLE PRECISION for dlarz
 COMPLEX for clarz
 COMPLEX*16 for zlarz
 Workspace array, DIMENSION
 (*n*) if *side* = 'L' or
 (*m*) if *side* = 'R'.

Output Parameters

c On exit, *c* is overwritten by the matrix H^*C if *side* = 'L',
 or C^*H if *side* = 'R'.

?larzb

*Applies a block reflector or its
 transpose/conjugate-transpose to a general matrix.*

Syntax

```
call slarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,  
work, ldwork )
```

```
call dlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,  
work, ldwork )
```

```
call clarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,  
work, ldwork )
```

```
call zlarzb( side, trans, direct, storev, m, n, k, l, v, ldv, t, ldt, c, ldc,  
work, ldwork )
```

Description

The routine applies a real/complex block reflector H or its transpose H^T (or H^H for complex flavors) to a real/complex distributed m -by- n matrix C from the left or the right. Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

side CHARACTER*1.
 If *side* = 'L': apply H or H^T/H^H from the left

If $side = 'R'$: apply H or H^T/H^H from the right
trans CHARACTER*1.
If $trans = 'N'$: apply H (No transpose)
If $trans='C'$: apply H^T/H^H (transpose/conjugate transpose)
direct CHARACTER*1.
Indicates how H is formed from a product of elementary reflectors
= 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward, not supported)
= 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
storev CHARACTER*1.
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Column-wise (not supported)
= 'R': Row-wise.
m INTEGER. The number of rows of the matrix C .
n INTEGER. The number of columns of the matrix C .
k INTEGER. The order of the matrix T (equal to the number of elementary reflectors whose product defines the block reflector).
l INTEGER. The number of columns of the matrix v containing the meaningful part of the Householder reflectors.
If $side = 'L'$, $m \geq 1 \geq 0$, if $side = 'R'$, $n \geq 1 \geq 0$.
v REAL for slarzb
DOUBLE PRECISION for dlarzb
COMPLEX for clarzb
COMPLEX*16 for zlarzb
Array, DIMENSION (ldv , nv).
If $storev = 'C'$, $nv = k$;
if $storev = 'R'$, $nv = l$.
ldv INTEGER. The leading dimension of the array v .
If $storev = 'C'$, $ldv \geq l$; if $storev = 'R'$, $ldv \geq k$.
t REAL for slarzb
DOUBLE PRECISION for dlarzb
COMPLEX for clarzb
COMPLEX*16 for zlarzb

	Array, DIMENSION (ldt, k). The triangular k -by- k matrix T in the representation of the block reflector.
ldt	INTEGER. The leading dimension of the array t . $ldt \geq k$.
c	REAL for slarzb DOUBLE PRECISION for dlarzb COMPLEX for clarzb COMPLEX*16 for zlarzb Array, DIMENSION (ldc, n). On entry, the m -by- n matrix C .
ldc	INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.
$work$	REAL for slarzb DOUBLE PRECISION for dlarzb COMPLEX for clarzb COMPLEX*16 for zlarzb Workspace array, DIMENSION ($ldwork, k$).
$ldwork$	INTEGER. The leading dimension of the array $work$. If $side = 'L'$, $ldwork \geq \max(1, n)$; if $side = 'R'$, $ldwork \geq \max(1, m)$.

Output Parameters

c	On exit, c is overwritten by H^*C , or H^T/H^H*C , or C^*H , or C^*H^T/H^H .

slarzt

Forms the triangular factor T of a block reflector H
 $= I - V^* T^* V^H$.

Syntax

```
call slarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
call dlarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
call clarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
call zlarzt( direct, storev, n, k, v, ldv, tau, t, ldt )
```

Description

The routine forms the triangular factor T of a real/complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If $direct = 'F'$, $H = H(1) * H(2) * \dots * H(k)$, and T is upper triangular.

If $direct = 'B'$, $H = H(k) * \dots * H(2) * H(1)$, and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array v , and $H = I - V^* T^* V^H$

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array v , and $H = I - V^* T^* V^H$

Currently, only $storev = 'R'$ and $direct = 'B'$ are supported.

Input Parameters

<i>direct</i>	CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: If $direct = 'F'$: $H = H(1) * H(2) * \dots * H(k)$ (forward, not supported) If $direct = 'B'$: $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	CHARACTER*1. Specifies how the vectors which define the elementary reflectors are stored (see also <i>Application Notes</i> below): If $storev = 'C'$: column-wise (not supported) If $storev = 'R'$: row-wise

<i>n</i>	INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	INTEGER. The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.
<i>v</i>	REAL for slarzt DOUBLE PRECISION for dlarzt COMPLEX for clarzt COMPLEX*16 for zlarzt Array, DIMENSION (<i>ldv</i> , <i>k</i>) if <i>storev</i> = 'C' (<i>ldv</i> , <i>n</i>) if <i>storev</i> = 'R' The matrix V .
<i>ldv</i>	INTEGER. The leading dimension of the array V . If <i>storev</i> = 'C', $ldv \geq \max(1, n)$; if <i>storev</i> = 'R', $ldv \geq k$.
<i>tau</i>	REAL for slarzt DOUBLE PRECISION for dlarzt COMPLEX for clarzt COMPLEX*16 for zlarzt Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$.
<i>ldt</i>	INTEGER. The leading dimension of the output array t . $ldt \geq k$.

Output Parameters

<i>t</i>	REAL for slarzt DOUBLE PRECISION for dlarzt COMPLEX for clarzt COMPLEX*16 for zlarzt Array, DIMENSION (<i>ldt</i> , <i>k</i>). The k -by- k triangular factor T of the block reflector. If <i>direct</i> = 'F', T is upper triangular; if <i>direct</i> = 'B', T is lower triangular. The rest of the array is not used.
<i>v</i>	The matrix V . See <i>Application Notes</i> below.

Application Notes

The shape of the matrix v and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

`direct = 'F' and storev = 'C':` `direct = 'F' and storev = 'R':`

$$v = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot \\ & 1 & \cdot \\ & & 1 \end{bmatrix}$$

$$\begin{array}{c} \text{---}V\text{---} \\ / \qquad \backslash \end{array} \begin{bmatrix} v_1 & v_2 & v_3 & v_1 & v_2 & \cdot & \cdot & \cdot & 1 \\ v_2 & v_2 & v_2 & v_2 & v_2 & \cdot & \cdot & \cdot & 1 \\ v_3 & v_3 & v_3 & v_3 & v_3 & \cdot & \cdot & 1 & \cdot \end{bmatrix}$$

`direct = 'B' and storev = 'C':` `direct = 'B' and storev = 'R':`

$$V = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 1 \end{bmatrix} \begin{bmatrix} v_1 & v_1 & v_1 \\ v_1 & v_1 & v_1 \\ v_1 & v_1 & v_1 \\ v_1 & v_1 & v_1 \\ v_1 & v_1 & v_1 \end{bmatrix}$$

$$\begin{matrix} & \text{---} V \text{---} \\ / & & \backslash \end{matrix} \begin{bmatrix} 1 & & & & v_1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & & & v_1 & v_1 & v_1 & v_1 & v_1 \\ & & 1 & & v_1 & v_1 & v_1 & v_1 & v_1 \end{bmatrix}$$

?las2

Computes singular values of a 2-by-2 triangular matrix.

Syntax

`call slas2( f, g, h, ssmin, ssmax )`

`call dlas2( f, g, h, ssmin, ssmax )`

Description

The routine ?las2 computes the singular values of the 2-by-2 matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, *ssmin* is the smaller singular value and *SSMAX* is the larger singular value.

Input Parameters

f, g, h REAL for `slas2`
 DOUBLE PRECISION for `dlas2`
 The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix,
 respectively.

Output Parameters

$ssmin, ssmax$ REAL for `slas2`
 DOUBLE PRECISION for `dlas2`
 The smaller and the larger singular values, respectively.

Application Notes

Barring over/underflow, all output quantities are correct to within a few units in the last place (*ulps*), even in the absence of a guard digit in addition/subtraction. In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows, or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?lascl

Multiplies a general rectangular matrix by a real scalar defined as c_{to}/c_{from} .

Syntax

```
call slascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call dlascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call clascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
call zlascl( type, kl, ku, cfrom, cto, m, n, a, lda, info )
```

Description

The routine `?lascl` multiplies the m -by- n real/complex matrix A by the real scalar c_{to}/c_{from} . The operation is performed without over/underflow as long as the final result $c_{to} * A(i, j) / c_{from}$ does not over/underflow.

type specifies that *A* may be full, upper triangular, lower triangular, upper Hessenberg, or banded.

Input Parameters

<i>type</i>	CHARACTER*1. This parameter specifies the storage type of the input matrix. = 'G': <i>A</i> is a full matrix. = 'L': <i>A</i> is a lower triangular matrix. = 'U': <i>A</i> is an upper triangular matrix. = 'H': <i>A</i> is an upper Hessenberg matrix. = 'B': <i>A</i> is a symmetric band matrix with lower bandwidth <i>kl</i> and upper bandwidth <i>ku</i> and with the only the lower half stored = 'Q': <i>A</i> is a symmetric band matrix with lower bandwidth <i>kl</i> and upper bandwidth <i>ku</i> and with the only the upper half stored. = 'Z': <i>A</i> is a band matrix with lower bandwidth <i>kl</i> and upper bandwidth <i>ku</i>.
<i>kl</i>	INTEGER. The lower bandwidth of <i>A</i>. Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.
<i>ku</i>	INTEGER. The upper bandwidth of <i>A</i>. Referenced only if <i>type</i> = 'B', 'Q' or 'Z'.
<i>cfrom, cto</i>	REAL for <code>slascl/clascl</code> DOUBLE PRECISION for <code>dlascl/zlascl</code> The matrix <i>A</i> is multiplied by <i>cto/cfrom</i>. <i>A</i>(<i>i</i>, <i>j</i>) is computed without over/underflow if the final result <i>cto</i>*<i>A</i>(<i>i</i>, <i>j</i>) / <i>cfrom</i> can be represented without over/underflow. <i>cfrom</i> must be nonzero.
<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i>. $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i>. $n \geq 0$.
<i>a</i>	REAL for <code>slascl</code> DOUBLE PRECISION for <code>dlascl</code> COMPLEX for <code>clascl</code> COMPLEX*16 for <code>zlascl</code> Array, DIMENSION (<i>lda</i>, <i>n</i>). The matrix to be multiplied by <i>cto/cfrom</i>. See <i>type</i> for the storage type.

lda INTEGER. The leading dimension of the array *a*.
 $lda \geq \max(1, m)$.

Output Parameters

a The multiplied matrix *A*.
info INTEGER.
 If *info* = 0 - successful exit
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.

?lasd0

Computes the singular values of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasd0( n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info )
call dlasd0( n, sqre, d, e, u, ldu, vt, ldvt, smlsiz, iwork, work, info )
```

Description

Using a divide and conquer approach, the routine ?lasd0 computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and offdiagonal e , where $m = n + sqre$.

The algorithm computes orthogonal matrices U and VT such that $B = U*S*VT$. The singular values s are overwritten on d .

The related subroutine ?lasda computes only the singular values, and optionally, the singular vectors in compact form.

Input Parameters

n INTEGER. On entry, the row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array d .
sqre INTEGER. Specifies the column dimension of the bidiagonal matrix.

	If $s_{qre} = 0$: the bidiagonal matrix has column dimension $m = n$. If $s_{qre} = 1$: the bidiagonal matrix has column dimension $m = n+1$.
<i>d</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION (n). On entry, <i>d</i> contains the main diagonal of the bidiagonal matrix.
<i>e</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION ($m-1$). Contains the subdiagonal entries of the bidiagonal matrix. On exit, <i>e</i> is destroyed.
<i>ldu</i>	INTEGER. On entry, leading dimension of the output array <i>u</i>.
<i>ldvt</i>	INTEGER. On entry, leading dimension of the output array <i>vt</i>.
<i>smlsiz</i>	INTEGER. On entry, maximum size of the subproblems at the bottom of the computation tree.
<i>iwork</i>	INTEGER. Workspace array, dimension must be at least $(8n)$.
<i>work</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Workspace array, dimension must be at least $(3m^2+2m)$.

Output Parameters

<i>d</i>	On exit <i>d</i>, If $info = 0$, contains singular values of the bidiagonal matrix.
<i>u</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION at least (ldq, n). On exit, <i>u</i> contains the left singular vectors.
<i>vt</i>	REAL for slasd0 DOUBLE PRECISION for dlasd0 Array, DIMENSION at least $(ldvt, m)$. On exit, <i>vt'</i> contains the right singular vectors.

info INTEGER.
 If *info* = 0: successful exit.
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.
 If *info* = 1, an singular value did not converge.

?lasd1

Computes the SVD of an upper bidiagonal matrix B of the specified size. Used by ?bdsdc.

Syntax

```
call slasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork,
work, info )
```

```
call dlasd1( nl, nr, sqre, d, alpha, beta, u, ldu, vt, ldvt, idxq, iwork,
work, info )
```

Description

This routine computes the SVD of an upper bidiagonal n -by- m matrix B , where $n = nl + nr + 1$ and $m = n + sqre$.

The routine ?lasd1 is called from ?lasd0.

A related subroutine ?lasd7 handles the case in which the singular values (and the singular vectors in factored form) are desired.

?lasd1 computes the SVD as follows:

$$VT = U(in) * \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1' & a & Z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out) * (D(out) \ 0) * VT(out)$$

where $Z' = (Z1' \ a \ Z2' \ b) = u' * VT'$, and u is a vector of dimension m with *alpha* and *beta* in the $nl+1$ and $nl+2$ -th entries and zeros elsewhere; and the entry b is empty if $sqre = 0$.

The left singular vectors of the original matrix are stored in u , and the transpose of the right singular vectors are stored in vt , and the singular values are in d . The algorithm consists of three stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or when there are zeros in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?lasd2`.
2. The second stage consists of calculating the updated singular values. This is done by finding the square roots of the roots of the secular equation via the routine `?lasd4` (as called by `?lasd3`). This routine also calculates the singular vectors of the current problem.
3. The final stage consists of computing the updated singular vectors directly using the updated singular values. The singular vectors for the current problem are multiplied with the singular vectors from the overall problem.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER. If <i>sqre</i> = 0: the lower block is an <i>nr</i> -by- <i>nr</i> square matrix. If <i>sqre</i> = 1: the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has row dimension $n = nl + nr + 1$, and column dimension $m = n + sqre$.
<i>d</i>	REAL for <code>slasd1</code> DOUBLE PRECISION for <code>dlsd1</code> Array, DIMENSION ($nl+nr+1$). $n = nl+nr+1$. On entry $d(1:nl, 1:nl)$ contains the singular values of the upper block; and $d(nl+2:n)$ contains the singular values of the lower block.
<i>alpha</i>	REAL for <code>slasd1</code> DOUBLE PRECISION for <code>dlsd1</code> Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for <code>slasd1</code>

	DOUBLE PRECISION for dlasd1
	Contains the off-diagonal element associated with the added row.
<i>u</i>	REAL for slasd1 DOUBLE PRECISION for dlasd1 Array, DIMENSION (<i>ldu</i> , <i>n</i>). On entry <i>u</i> (1: <i>nl</i> , 1: <i>nl</i>) contains the left singular vectors of the upper block; <i>u</i> (<i>nl</i> +2: <i>n</i> , <i>nl</i> +2: <i>n</i>) contains the left singular vectors of the lower block.
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i> . <i>ldu</i> ≥ max(1, <i>n</i>).
<i>vt</i>	REAL for slasd1 DOUBLE PRECISION for dlasd1 Array, DIMENSION (<i>ldvt</i> , <i>m</i>), where <i>m</i> = <i>n</i> + <i>sqr</i> . On entry <i>vt</i> (1: <i>nl</i> +1, 1: <i>nl</i> +1) ' contains the right singular vectors of the upper block; <i>vt</i> (<i>nl</i> +2: <i>m</i> , <i>nl</i> +2: <i>m</i>) ' contains the right singular vectors of the lower block.
<i>ldvt</i>	INTEGER. The leading dimension of the array <i>vt</i> . <i>ldvt</i> ≥ max(1, <i>M</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (4 <i>n</i>).
<i>work</i>	REAL for slasd1 DOUBLE PRECISION for dlasd1 Workspace array, DIMENSION (3 <i>m</i> ₂ + 2 <i>m</i>).

Output Parameters

<i>d</i>	On exit <i>d</i> (1: <i>n</i>) contains the singular values of the modified matrix.
<i>alpha</i>	On exit, the diagonal element associated with the added row deflated by max(abs(<i>alpha</i>), abs(<i>beta</i>), abs(<i>D</i> (<i>I</i>))), <i>I</i> = 1, <i>n</i> .
<i>beta</i>	On exit, the off-diagonal element associated with the added row deflated by max(abs(<i>alpha</i>), abs(<i>beta</i>), abs(<i>D</i> (<i>I</i>))), <i>I</i> = 1, <i>n</i> .

<code>u</code>	On exit <code>u</code> contains the left singular vectors of the bidiagonal matrix.
<code>vt</code>	On exit <code>vt'</code> contains the right singular vectors of the bidiagonal matrix.
<code>idxq</code>	INTEGER Array, DIMENSION (n). Contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, $d(idxq(i = 1, n))$ will be in ascending order.
<code>info</code>	INTEGER. If <code>info = 0</code> : successful exit. If <code>info = -i < 0</code> , the i -th argument had an illegal value. If <code>info = 1</code> , an singular value did not converge.

?lasd2

Merges the two sets of singular values together into a single sorted set. Used by ?bdsdc.

Syntax

```
call slasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma,
u2, ldu2, vt2, ldvt2, idxp, idx, idxp, idxq, coltyp, info )

call dlasd2( nl, nr, sqre, k, d, z, alpha, beta, u, ldu, vt, ldvt, dsigma,
u2, ldu2, vt2, ldvt2, idxp, idx, idxp, idxq, coltyp, info )
```

Description

The routine `?lasd2` merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the `z` vector. For each such occurrence the order of the related secular equation problem is reduced by one.

The routine `?lasd2` is called from `?lasd1`.

Input Parameters

`nl` INTEGER. The row dimension of the upper block.
 $nl \geq 1$.

<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER. If <i>sqre</i> = 0): the lower block is an <i>nr</i>-by-<i>nr</i> square matrix If <i>sqre</i> = 1): the lower block is an <i>nr</i>-by-(<i>nr</i>+1) rectangular matrix. The bidiagonal matrix has $n = n1 + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<i>d</i>	REAL for slasd2 DOUBLE PRECISION for dlasd2 Array, DIMENSION (<i>n</i>). On entry <i>d</i> contains the singular values of the two submatrices to be combined.
<i>alpha</i>	REAL for slasd2 DOUBLE PRECISION for dlasd2 Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for slasd2 DOUBLE PRECISION for dlasd2 Contains the off-diagonal element associated with the added row.
<i>u</i>	REAL for slasd2 DOUBLE PRECISION for dlasd2 Array, DIMENSION (<i>ldu</i>, <i>n</i>). On entry <i>u</i> contains the left singular vectors of two submatrices in the two square blocks with corners at (1,1), (<i>n1</i>, <i>n1</i>), and (<i>n1</i>+2, <i>n1</i>+2), (<i>n</i>,<i>n</i>).
<i>ldu</i>	INTEGER. The leading dimension of the array <i>u</i>. $ldu \geq n$.
<i>ldu2</i>	INTEGER. The leading dimension of the output array <i>u2</i>. $ldu2 \geq n$.
<i>vt</i>	REAL for slasd2 DOUBLE PRECISION for dlasd2 Array, DIMENSION (<i>ldvt</i>, <i>m</i>). On entry, <i>vt'</i> contains the right singular vectors of two submatrices in the two square blocks with corners at (1,1), (<i>n1</i>+1, <i>n1</i>+1), and (<i>n1</i>+2, <i>n1</i>+2), (<i>m</i>, <i>m</i>).

<i>ldvt</i>	INTEGER. The leading dimension of the array <i>vt</i> . $ldvt \geq m$.
<i>ldvt2</i>	INTEGER. The leading dimension of the output array <i>vt2</i> . $ldvt2 \geq m$.
<i>idxp</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to place deflated values of <i>D</i> at the end of the array. On output <i>idxp</i> (2: <i>k</i>) points to the nondeflated <i>d</i> -values and <i>idxp</i> (<i>k</i> +1: <i>n</i>) points to the deflated singular values.
<i>idx</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.
<i>coltyp</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). As workspace, this array contains a label that indicates which of the following types a column in the <i>u2</i> matrix or a row in the <i>vt2</i> matrix is: 1 : non-zero in the upper half only 2 : non-zero in the lower half only 3 : dense 4 : deflated.
<i>idxq</i>	INTEGER. Array, DIMENSION (<i>n</i>). This parameter contains the permutation that separately sorts the two sub-problems in <i>D</i> into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have <i>n</i> l+1 added to their values.

Output Parameters

<i>k</i>	INTEGER. Contains the dimension of the non-deflated matrix, This is the order of the related secular equation. $1 \leq k \leq n$.
<i>d</i>	On exit <i>D</i> contains the trailing (<i>n</i> - <i>k</i>) updated singular values (those which were deflated) sorted into increasing order.

<i>u</i>	On exit <i>u</i> contains the trailing $(n-k)$ updated left singular vectors (those which were deflated) in its last $n-k$ columns.
<i>z</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlsd2</code> Array, DIMENSION (<i>n</i>). On exit, <i>z</i> contains the updating row vector in the secular equation.
<i>dsigma</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlsd2</code> Array, DIMENSION (<i>n</i>). Contains a copy of the diagonal elements ($k-1$ singular values and one zero) in the secular equation.
<i>u2</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlsd2</code> Array, DIMENSION (<i>ldu2</i> , <i>n</i>). Contains a copy of the first $k-1$ left singular vectors which will be used by <code>?lasd3</code> in a matrix multiply (<code>?gemm</code>) to solve for the new left singular vectors. <i>u2</i> is arranged into four blocks. The first block contains a column with 1 at $n1+1$ and zero everywhere else; the second block contains non-zero entries only at and above $n1$; the third contains non-zero entries only below $n1+1$; and the fourth is dense.
<i>vt</i>	On exit, <i>vt'</i> contains the trailing $(n-k)$ updated right singular vectors (those which were deflated) in its last $n-k$ columns. In case <i>sqr</i> = 1, the last row of <i>vt</i> spans the right null space.
<i>vt2</i>	REAL for <code>slasd2</code> DOUBLE PRECISION for <code>dlsd2</code> Array, DIMENSION (<i>ldvt2</i> , <i>n</i>). <i>vt2'</i> contains a copy of the first k right singular vectors which will be used by <code>?lasd3</code> in a matrix multiply (<code>?gemm</code>) to solve for the new right singular vectors. <i>vt2</i> is arranged into three blocks. The first block contains a row that corresponds to the special 0 diagonal element in <i>sigma</i> ; the second block contains non-zeros only at and before $n1 + 1$; the third block contains non-zeros only at and after $n1 + 2$.

<i>idxc</i>	INTEGER. Array, DIMENSION (<i>n</i>). This will contain the permutation used to arrange the columns of the deflated <i>u</i> matrix into three groups: the first group contains non-zero entries only at and above <i>nl</i> , the second contains non-zero entries only below <i>nl+2</i> , and the third is dense.
<i>coltyp</i>	On exit, it is an array of dimension 4, with <i>coltyp</i> (<i>i</i>) being the dimension of the <i>i</i> -th type columns.
<i>info</i>	INTEGER. If <i>info</i> = 0): successful exit If <i>info</i> = - <i>i</i> < 0, the <i>i</i> -th argument had an illegal value.

?lasd3

Finds all square roots of the roots of the secular equation, as defined by the values in D and Z, and then updates the singular vectors by matrix multiplication. Used by ?bdsdc.

Syntax

```
call slasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt,
vt2, ldvt2, idxc, ctot, z, info )

call dlasd3( nl, nr, sqre, k, d, q, ldq, dsigma, u, ldu, u2, ldu2, vt, ldvt,
vt2, ldvt2, idxc, ctot, z, info )
```

Description

The routine ?lasd3 finds all the square roots of the roots of the secular equation, as defined by the values in *D* and *Z*.

It makes the appropriate calls to ?lasd4 and then updates the singular vectors by matrix multiplication.

The routine ?lasd3 is called from ?lasd1.

Input Parameters

<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block.

$nr \geq 1$.

sqre INTEGER.
 If $sqre = 0$): the lower block is an nr -by- nr square matrix.
 If $sqre = 1$): the lower block is an nr -by- $(nr+1)$ rectangular matrix. The bidiagonal matrix has $n = n1 + nr + 1$ rows and $m = n + sqre \geq n$ columns.

k INTEGER. The size of the secular equation, $1 \leq k \leq n$.

q REAL for slasd3
 DOUBLE PRECISION for dlasd3
 Workspace array, DIMENSION at least (ldq, k).

ldq INTEGER. The leading dimension of the array *q*.
 $ldq \geq k$.

dsigma REAL for slasd3
 DOUBLE PRECISION for dlasd3
 Array, DIMENSION (k). The first k elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.

ldu INTEGER. The leading dimension of the array *u*.
 $ldu \geq n$.

u2 REAL for slasd3
 DOUBLE PRECISION for dlasd3
 Array, DIMENSION ($ldu2, n$).
 The first k columns of this matrix contain the non-deflated left singular vectors for the split problem.

ldu2 INTEGER. The leading dimension of the array *u2*.
 $ldu2 \geq n$.

ldvt INTEGER. The leading dimension of the array *vt*.
 $ldvt \geq n$.

vt2 REAL for slasd3
 DOUBLE PRECISION for dlasd3
 Array, DIMENSION ($ldvt2, n$).
 The first k columns of *vt2'* contain the non-deflated right singular vectors for the split problem.

<i>ldvt2</i>	INTEGER. The leading dimension of the array <i>vt2</i> . $ldvt2 \geq n$.
<i>idxc</i>	INTEGER. Array, DIMENSION (<i>n</i>). The permutation used to arrange the columns of <i>u</i> (and rows of <i>vt</i>) into three groups: the first group contains non-zero entries only at and above (or before) <i>nl + 1</i> ; the second contains non-zero entries only at and below (or after) <i>nl+2</i> ; and the third is dense. The first column of <i>u</i> and the row of <i>vt</i> are treated separately, however. The rows of the singular vectors found by ?lasd4 must be likewise permuted before the matrix multiplies can take place.
<i>ctot</i>	INTEGER. Array, DIMENSION (4). A count of the total number of the various types of columns in <i>u</i> (or rows in <i>vt</i>), as described in <i>idxc</i> . The fourth column type is any column which has been deflated.
<i>z</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the components of the deflation-adjusted updating row vector.

Output Parameters

<i>d</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array, DIMENSION (<i>k</i>). On exit the square roots of the roots of the secular equation, in ascending order.
<i>u</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array, DIMENSION (<i>ldu</i> , <i>n</i>). The last <i>n - k</i> columns of this matrix contain the deflated left singular vectors.
<i>vt</i>	REAL for slasd3 DOUBLE PRECISION for dlasd3 Array, DIMENSION (<i>ldvt</i> , <i>m</i>).

The last $m - k$ columns of vt' contain the deflated right singular vectors.

vt2 Destroyed on exit.

z Destroyed on exit.

info INTEGER.
 If *info* = 0): successful exit.
 If *info* = -*i* < 0, the *i*-th argument had an illegal value.
 If *info* = 1, an singular value did not converge.

Application Notes

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

?lasd4

*Computes the square root of the *i*-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. Used by ?bdsdc.*

Syntax

```
call slasd4( n, i, d, z, delta, rho, sigma, work, info )
call dlasd4( n, i, d, z, delta, rho, sigma, work, info )
```

Description

This routine computes the square root of the *i*-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix whose entries are given as the squares of the corresponding entries in the array *d*, and that $0 \leq d(i) < d(j)$ for $i < j$ and that $\rho > 0$. This is arranged by the calling routine, and is no loss in generality. The rank-one modified system is thus

$$\text{diag}(d) * \text{diag}(d) + \rho * z * z^T,$$

where the Euclidean norm of *z* is equal to 1. The method consists of approximating the rational functions in the secular equation by simpler interpolating rational functions.

Input Parameters

<i>n</i>	INTEGER. The length of all arrays.
<i>i</i>	INTEGER. The index of the eigenvalue to be computed. $1 \leq i \leq n$.
<i>d</i>	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (<i>n</i>). The original eigenvalues. They must be in order, $0 \leq d(i) < d(j)$ for $i < j$.
<i>z</i>	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (<i>n</i>). The components of the updating vector.
<i>rho</i>	REAL for slasd4 DOUBLE PRECISION for dlasd4 The scalar in the symmetric updating formula.
<i>work</i>	REAL for slasd4 DOUBLE PRECISION for dlasd4 Workspace array, DIMENSION (<i>n</i>). If $n \neq 1$, <i>work</i> contains ($d(j) + \text{sigma}_i$) in its <i>j</i> -th component. If $n = 1$, then <i>work</i> (1) = 1.

Output Parameters

<i>delta</i>	REAL for slasd4 DOUBLE PRECISION for dlasd4 Array, DIMENSION (<i>n</i>). If $n \neq 1$, <i>delta</i> contains ($d(j) - \text{sigma}_i$) in its <i>j</i> -th component. If $n = 1$, then <i>delta</i> (1) = 1. The vector <i>delta</i> contains the information necessary to construct the (singular) eigenvectors.
<i>sigma</i>	REAL for slasd4 DOUBLE PRECISION for dlasd4

info The computed σ_i , the i -th updated eigenvalue.
 INTEGER.
 = 0: successful exit
 > 0: If *info* = 1, the updating process failed.

?lasd5

Computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by ?bdsdc.

Syntax

```
call slasd5( i, d, z, delta, rho, dsigma, work )
call dlasd5( i, d, z, delta, rho, dsigma, work )
```

Description

This routine computes the square root of the i -th eigenvalue of a positive symmetric rank-one modification of a 2-by-2 diagonal matrix $\text{diag}(d) * \text{diag}(d) + \rho * Z * Z^T$

The diagonal entries in the array d must satisfy $0 \leq d(i) < d(j)$ for $i < j$, ρ must be greater than 0, and that the Euclidean norm of the vector z is equal to 1.

Input Parameters

i *INTEGER*. The index of the eigenvalue to be computed. $i = 1$ or $i = 2$.

d *REAL* for *slasd5*
 DOUBLE PRECISION for *dlasd5*
 Array, dimension (2).
 The original eigenvalues, $0 \leq d(1) < d(2)$.

z *REAL* for *slasd5*
 DOUBLE PRECISION for *dlasd5*
 Array, dimension (2).
 The components of the updating vector.

rho *REAL* for *slasd5*
 DOUBLE PRECISION for *dlasd5*
 The scalar in the symmetric updating formula.

work REAL for slasd5
DOUBLE PRECISION for dlasd5.
Workspace array, dimension (2). Contains ($d(j) + \sigma_i$) in its j -th component.

Output Parameters

delta REAL for slasd5
DOUBLE PRECISION for dlasd5.
Array, dimension (2).
Contains ($d(j) - \sigma_i$) in its j -th component. The vector *delta* contains the information necessary to construct the eigenvectors.

dsigma REAL for slasd5
DOUBLE PRECISION for dlasd5.
The computed σ_i , the i -th updated eigenvalue.

?lasd6

Computes the SVD of an updated upper bidiagonal matrix obtained by merging two smaller ones by appending a row. Used by ?bdsdc.

Syntax

```
call slasd6( icompg, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr,
            givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork,
            info )
```

```
call dlasd6( icompg, nl, nr, sqre, d, vf, vl, alpha, beta, idxq, perm, givptr,
            givcol, ldgcol, givnum, ldgnum, poles, difl, difr, z, k, c, s, work, iwork,
            info )
```

Description

The routine ?lasd6 computes the *SVD* of an updated upper bidiagonal matrix B obtained by merging two smaller ones by appending a row. This routine is used only for the problem which requires all singular values and optionally singular vector matrices in factored form. B is an n -by- m matrix with $n = nl + nr + 1$ and $m = n + sqre$. A related subroutine, ?lasd1, handles the case in which all singular values and singular vectors of the bidiagonal matrix are desired. ?lasd6 computes the *SVD* as follows:

$$B = U(in) * \begin{bmatrix} D1(in) & 0 & 0 & 0 \\ Z1' & a & Z2' & b \\ 0 & 0 & D2(in) & 0 \end{bmatrix} * VT(in)$$

$$= U(out) * (D(out) * VT(out))$$

where $Z' = (Z1' \ a \ Z2' \ b) = u' * VT'$, and u is a vector of dimension m with $alpha$ and $beta$ in the $nl+1$ and $nl+2$ -th entries and zeros elsewhere; and the entry b is empty if $sqr = 0$.

The singular values of B can be computed using $D1$, $D2$, the first components of all the right singular vectors of the lower block, and the last components of all the right singular vectors of the upper block. These components are stored and updated in vf and vl , respectively, in `?lasd6`. Hence U and VT are not explicitly referenced.

The singular values are stored in D . The algorithm consists of two stages:

1. The first stage consists of deflating the size of the problem when there are multiple singular values or if there is a zero in the z vector. For each such occurrence the dimension of the secular equation problem is reduced by one. This stage is performed by the routine `?lasd7`.
2. The second stage consists of calculating the updated singular values. This is done by finding the roots of the secular equation via the routine `?lasd4` (as called by `?lasd8`). This routine also updates vf and vl and computes the distances between the updated singular values and the old singular values. `?lasd6` is called from `?lasda`.

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form: = 0: Compute singular values only = 1: Compute singular vectors in factored form as well.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqr</i>	INTEGER. = 0: the lower block is an nr -by- nr square matrix.

	= 1: the lower block is an nr-by-$(nr+1)$ rectangular matrix. The bidiagonal matrix has row dimension $n=nl+nr+1$, and column dimension $m = n + sqre$.
<i>d</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension ($nl+nr+1$). On entry $d(1:nl,1:nl)$ contains the singular values of the upper block, and $d(nl+2:n)$ contains the singular values of the lower block.
<i>vf</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (m). On entry, $vf(1:nl+1)$ contains the first components of all right singular vectors of the upper block; and $vf(nl+2:m)$ contains the first components of all right singular vectors of the lower block.
<i>vl</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (m). On entry, $vl(1:nl+1)$ contains the last components of all right singular vectors of the upper block; and $vl(nl+2:m)$ contains the last components of all right singular vectors of the lower block.
<i>alpha</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Contains the off-diagonal element associated with the added row.
<i>ldgcol</i>	INTEGER. The leading dimension of the output array <i>givcol</i>, must be at least n.
<i>ldgnum</i>	INTEGER. The leading dimension of the output arrays <i>givnum</i> and <i>poles</i>, must be at least n.
<i>work</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6

iwork Workspace array, dimension ($4m$).
 INTEGER.
 Workspace array, dimension ($3n$).

Output Parameters

d On exit $d(1:n)$ contains the singular values of the modified matrix.

vf On exit, *vf* contains the first components of all right singular vectors of the bidiagonal matrix.

vl On exit, *vl* contains the last components of all right singular vectors of the bidiagonal matrix.

alpha On exit, the diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(D(I))), I = 1, n$.

beta On exit, the off-diagonal element associated with the added row deflated by $\max(\text{abs}(\text{alpha}), \text{abs}(\text{beta}), \text{abs}(D(I))), I = 1, n$.

idxq INTEGER.
 Array, dimension (n). This contains the permutation which will reintegrate the subproblem just solved back into sorted order, that is, $d(\text{idxq}(i = 1, n))$ will be in ascending order.

perm INTEGER.
 Array, dimension (n). The permutations (from deflation and sorting) to be applied to each block. Not referenced if $\text{icompq} = 0$.

givptr INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if $\text{icompq} = 0$.

givcol INTEGER.
 Array, dimension ($\text{ldgcol}, 2$). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if $\text{icompq} = 0$.

givnum REAL for `slasd6`
 DOUBLE PRECISION for `dlsd6`

	Array, dimension (<i>ldgnum</i>, 2). Each number indicates the <i>c</i> or <i>s</i> value to be used in the corresponding Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>poles</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>ldgnum</i>, 2). On exit, <i>poles</i>(1,*) is an array containing the new singular values obtained from solving the secular equation, and <i>poles</i>(2,*) is an array containing the poles in the secular equation. Not referenced if <i>icompq</i> = 0.
<i>difl</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>n</i>). On exit, <i>difl</i>(<i>i</i>) is the distance between <i>i</i>-th updated (undeflated) singular value and the <i>i</i>-th (undeflated) old singular value.
<i>difr</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>ldgnum</i>, 2) if <i>icompq</i> = 1 and dimension (<i>n</i>) if <i>icompq</i> = 0. On exit, <i>difr</i>(<i>i</i>, 1) is the distance between <i>i</i>-th updated (undeflated) singular value and the <i>i</i>+1-th (undeflated) old singular value. If <i>icompq</i> = 1, <i>difr</i>(1: <i>k</i>, 2) is an array containing the normalizing factors for the right singular vector matrix. See ?lasd8 for details on <i>difl</i> and <i>difr</i>.
<i>z</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6 Array, dimension (<i>m</i>). The first elements of this array contain the components of the deflation-adjusted updating row vector.
<i>k</i>	INTEGER. Contains the dimension of the non-deflated matrix. This is the order of the related secular equation. $1 \leq k \leq n$.
<i>c</i>	REAL for slasd6 DOUBLE PRECISION for dlasd6

c contains garbage if *sqre* = 0 and the *c*-value of a Givens rotation related to the right null space if *sqre* = 1.

s REAL for slasd6
DOUBLE PRECISION for dlasd6
s contains garbage if *sqre* = 0 and the *s*-value of a Givens rotation related to the right null space if *sqre* = 1.

info INTEGER.
= 0: successful exit.
< 0: if *info* = -*i*, the *i*-th argument had an illegal value.
> 0: if *info* = 1, an singular value did not converge

?lasd7

Merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. Used by ?bdsdc.

Syntax

```
call slasd7( icompg, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta,
dsigma, idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s,
info )
```

```
call dlasd7( icompg, nl, nr, sqre, k, d, z, zw, vf, vfw, vl, vlw, alpha, beta,
dsigma, idx, idxp, idxq, perm, givptr, givcol, ldgcol, givnum, ldgnum, c, s,
info )
```

Description

The routine ?lasd7 merges the two sets of singular values together into a single sorted set. Then it tries to deflate the size of the problem. There are two ways in which deflation can occur: when two or more singular values are close together or if there is a tiny entry in the *z* vector. For each such occurrence the order of the related secular equation problem is reduced by one. ?lasd7 is called from ?lasd6.

Input Parameters

icompg INTEGER. Specifies whether singular vectors are to be computed in compact form, as follows:
= 0: Compute singular values only.

	= 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>nl</i>	INTEGER. The row dimension of the upper block. $nl \geq 1$.
<i>nr</i>	INTEGER. The row dimension of the lower block. $nr \geq 1$.
<i>sqre</i>	INTEGER. = 0: the lower block is an <i>nr</i> -by- <i>nr</i> square matrix. = 1: the lower block is an <i>nr</i> -by-(<i>nr</i> +1) rectangular matrix. The bidiagonal matrix has $n = nl + nr + 1$ rows and $m = n + sqre \geq n$ columns.
<i>d</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>n</i>). On entry <i>d</i> contains the singular values of the two submatrices to be combined.
<i>zw</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). Workspace for <i>z</i> .
<i>vf</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). On entry, <i>vf</i> (1: <i>nl</i> +1) contains the first components of all right singular vectors of the upper block; and <i>vf</i> (<i>nl</i> +2: <i>m</i>) contains the first components of all right singular vectors of the lower block.
<i>vfw</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>). Workspace for <i>vf</i> .
<i>vl</i>	REAL for slasd7 DOUBLE PRECISION for dlasd7 Array, DIMENSION (<i>m</i>).

	On entry, $vl(1:nl+1)$ contains the last components of all right singular vectors of the upper block; and $vl(nl+2:m)$ contains the last components of all right singular vectors of the lower block.
<i>VLW</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlsd7</code> Array, DIMENSION (<i>m</i>). Workspace for VL.
<i>alpha</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlsd7</code>. Contains the diagonal element associated with the added row.
<i>beta</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlsd7</code> Contains the off-diagonal element associated with the added row.
<i>idx</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to sort the contents of <i>d</i> into ascending order.
<i>idxp</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). This will contain the permutation used to place deflated values of <i>d</i> at the end of the array.
<i>idxq</i>	INTEGER. Array, DIMENSION (<i>n</i>). This contains the permutation which separately sorts the two sub-problems in <i>d</i> into ascending order. Note that entries in the first half of this permutation must first be moved one position backward; and entries in the second half must first have $nl+1$ added to their values.
<i>ldgcol</i>	INTEGER. The leading dimension of the output array <i>givcol</i>, must be at least <i>n</i>.
<i>ldgnum</i>	INTEGER. The leading dimension of the output array <i>givnum</i>, must be at least <i>n</i>.

Output Parameters

<i>k</i>	INTEGER. Contains the dimension of the non-deflated matrix, this is the order of the related secular equation. $1 \leq k \leq n$.
<i>d</i>	On exit, <i>d</i> contains the trailing (<i>n-k</i>) updated singular values (those which were deflated) sorted into increasing order.
<i>z</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlsd7</code>. Array, DIMENSION (<i>m</i>). On exit, <i>z</i> contains the updating row vector in the secular equation.
<i>vf</i>	On exit, <i>vf</i> contains the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the last components of all right singular vectors of the bidiagonal matrix.
<i>dsigma</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlsd7</code>. Array, DIMENSION (<i>n</i>). Contains a copy of the diagonal elements (<i>k</i>-1 singular values and one zero) in the secular equation.
<i>idxp</i>	On output, <i>idxp</i>(2: <i>k</i>) points to the nondeflated <i>d</i>-values and <i>idxp</i>(<i>k</i>+1:<i>n</i>) points to the deflated singular values.
<i>perm</i>	INTEGER. Array, DIMENSION (<i>n</i>). The permutations (from deflation and sorting) to be applied to each singular block. Not referenced if <i>icompq</i> = 0.
<i>givptr</i>	INTEGER. The number of Givens rotations which took place in this subproblem. Not referenced if <i>icompq</i> = 0.
<i>givcol</i>	INTEGER. Array, DIMENSION (<i>ldgcol</i>, 2). Each pair of numbers indicates a pair of columns to take place in a Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>givnum</i>	REAL for <code>slasd7</code> DOUBLE PRECISION for <code>dlsd7</code>.

	Array, DIMENSION (<i>ldgnum</i> , 2). Each number indicates the <i>c</i> or <i>s</i> value to be used in the corresponding Givens rotation. Not referenced if <i>icompq</i> = 0.
<i>c</i>	REAL for <i>slasd7</i> . DOUBLE PRECISION for <i>dlasd7</i> . If <i>sqre</i> = 0, then <i>c</i> contains garbage, and if <i>sqre</i> = 1, then <i>c</i> contains <i>c</i> -value of a Givens rotation related to the right null space.
<i>s</i>	REAL for <i>slasd7</i> . DOUBLE PRECISION for <i>dlasd7</i> . If <i>sqre</i> = 0, then <i>s</i> contains garbage, and if <i>sqre</i> = 1, then <i>s</i> contains <i>s</i> -value of a Givens rotation related to the right null space.
<i>info</i>	INTEGER. = 0: successful exit. < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value.

?lasd8

*Finds the square roots of the roots of the secular equation, and stores, for each element in *D*, the distance to its two nearest poles. Used by ?bdsdc.*

Syntax

```
call slasd8( icompq, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info
)
call dlasd8( icompq, k, d, z, vf, vl, difl, difr, lddifr, dsigma, work, info
)
```

Description

The routine ?lasd8 finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to ?lasd4, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. ?lasd8 is called from ?lasd6.

Input Parameters

<i>icompq</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine: = 0: Compute singular values only. = 1: Compute singular vectors in factored form as well.
<i>k</i>	INTEGER. The number of terms in the rational function to be solved by ?lasd4. $k \geq 1$.
<i>z</i>	REAL for slasd8 DOUBLE PRECISION for dlasd8. Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the components of the deflation-adjusted updating row vector.
<i>vf</i>	REAL for slasd8 DOUBLE PRECISION for dlasd8. Array, DIMENSION (<i>k</i>). On entry, <i>vf</i> contains information passed through dbede8.
<i>vl</i>	REAL for slasd8 DOUBLE PRECISION for dlasd8. Array, DIMENSION (<i>k</i>). On entry, <i>vl</i> contains information passed through dbede8.
<i>lddifr</i>	INTEGER. The leading dimension of the output array <i>difr</i>, must be at least <i>k</i>.
<i>dsigma</i>	REAL for slasd8 DOUBLE PRECISION for dlasd8. Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>work</i>	REAL for slasd8 DOUBLE PRECISION for dlasd8. Workspace array, DIMENSION at least $(3k)$.

Output Parameters

<i>d</i>	REAL for slasd8 DOUBLE PRECISION for dlasd8.

Array, `DIMENSION ( k )`.
 On output, *D* contains the updated singular values.

vf
 On exit, *vf* contains the first *k* components of the first components of all right singular vectors of the bidiagonal matrix.

vl
 On exit, *vl* contains the first *k* components of the last components of all right singular vectors of the bidiagonal matrix.

difl
 REAL for `slasd8`
 DOUBLE PRECISION for `dlasd8`.
 Array, `DIMENSION ( k )`. On exit, $difl(i) = d(i) - dsigma(i)$.

difr
 REAL for `slasd8`
 DOUBLE PRECISION for `dlasd8`.
 Array,
`DIMENSION ( lddifr, 2 )` if *icompg* = 1 and
`DIMENSION ( k )` if *icompg* = 0.
 On exit, $difr(i,1) = d(i) - dsigma(i+1)$, $difr(k,1)$ is not defined and will not be referenced. If *icompg* = 1, $difr(1:k,2)$ is an array containing the normalizing factors for the right singular vector matrix.

info
 INTEGER.
 = 0: successful exit.
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value.
 > 0: If *info* = 1, an singular value did not converge.

?lasd9

*Finds the square roots of the roots of the secular equation, and stores, for each element in *D*, the distance to its two nearest poles. Used by ?bdsdc.*

Syntax

```
call slasd9( icompg, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
call dlasd9( icompg, ldu, k, d, z, vf, vl, difl, difr, dsigma, work, info )
```

Description

The routine `?lasd9` finds the square roots of the roots of the secular equation, as defined by the values in *dsigma* and *z*. It makes the appropriate calls to `?lasd4`, and stores, for each element in *d*, the distance to its two nearest poles (elements in *dsigma*). It also updates the arrays *vf* and *vl*, the first and last components of all the right singular vectors of the original bidiagonal matrix. `?lasd9` is called from `?lasd7`.

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in factored form in the calling routine: If <i>icompg</i> = 0, compute singular values only; If <i>icompg</i> = 1, compute singular vector matrices in factored form also.
<i>k</i>	INTEGER. The number of terms in the rational function to be solved by <code>slasd4</code>. $k \geq 1$.
<i>dsigma</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, DIMENSION(<i>k</i>). The first <i>k</i> elements of this array contain the old roots of the deflated updating problem. These are the poles of the secular equation.
<i>z</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, DIMENSION (<i>k</i>). The first <i>k</i> elements of this array contain the components of the deflation-adjusted updating row vector.
<i>vf</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, DIMENSION(<i>k</i>). On entry, <i>vf</i> contains information passed through <code>sbede8</code>.
<i>vl</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, DIMENSION(<i>k</i>). On entry, <i>vl</i> contains information passed through <code>sbede8</code>.
<i>work</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>.

Workspace array, `DIMENSION` at least $(3k)$.

Output Parameters

<i>d</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, <code>DIMENSION(k)</code>. <i>d</i>(<i>i</i>) contains the updated singular values.
<i>vf</i>	On exit, <i>vf</i> contains the first <i>k</i> components of the first components of all right singular vectors of the bidiagonal matrix.
<i>vl</i>	On exit, <i>vl</i> contains the first <i>k</i> components of the last components of all right singular vectors of the bidiagonal matrix.
<i>difl</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, <code>DIMENSION(k)</code>. On exit, <i>difl</i>(<i>i</i>) = <i>d</i>(<i>i</i>) - <i>dsigma</i>(<i>i</i>).
<i>difr</i>	REAL for <code>slasd9</code> DOUBLE PRECISION for <code>dlasd9</code>. Array, <code>DIMENSION(ldu, 2)</code> if <i>icompg</i> = 1 and <code>DIMENSION(k)</code> if <i>icompg</i> = 0. On exit, <i>difr</i>(<i>i</i>, 1) = <i>d</i>(<i>i</i>) - <i>dsigma</i>(<i>i</i>+1), <i>difr</i>(<i>k</i>, 1) is not defined and will not be referenced. If <i>icompg</i> = 1, <i>difr</i>(1:<i>k</i>, 2) is an array containing the normalizing factors for the right singular vector matrix.
<i>info</i>	INTEGER. = 0: successful exit. < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value. > 0: If <i>info</i> = 1, an singular value did not converge

?lasda

Computes the singular value decomposition (SVD) of a real upper bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasda( icompg, smlsiz, n, sqre, d, e, u, ldu, vt, k, difl, difr, z,
            poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )

call dlasda( icompg, smlsiz, n, sqre, d, e, u, ldu, vt, k, difl, difr, z,
            poles, givptr, givcol, ldgcol, perm, givnum, c, s, work, iwork, info )
```

Description

Using a divide and conquer approach, ?lasda computes the singular value decomposition (SVD) of a real upper bidiagonal n -by- m matrix B with diagonal d and off-diagonal e , where $m = n + sqre$.

The algorithm computes the singular values in the $SVD\ B = U*S*V^T$. The orthogonal matrices U and V^T are optionally computed in compact form. A related subroutine ?lasd0 computes the singular values and the singular vectors in explicit form.

Input Parameters

<i>icompg</i>	INTEGER. Specifies whether singular vectors are to be computed in compact form, as follows: = 0: Compute singular values only. = 1: Compute singular vectors of upper bidiagonal matrix in compact form.
<i>smlsiz</i>	INTEGER. The maximum size of the subproblems at the bottom of the computation tree.
<i>n</i>	INTEGER. The row dimension of the upper bidiagonal matrix. This is also the dimension of the main diagonal array d .
<i>sqre</i>	INTEGER. Specifies the column dimension of the bidiagonal matrix. If $sqre = 0$: the bidiagonal matrix has column dimension $m = n$

If $s_{qre} = 1$: the bidiagonal matrix has column dimension $m = n + 1$.

d REAL for slasda
DOUBLE PRECISION for dlasda.
Array, DIMENSION (n). On entry, *d* contains the main diagonal of the bidiagonal matrix.

e REAL for slasda
DOUBLE PRECISION for dlasda.
Array, DIMENSION ($m - 1$). Contains the subdiagonal entries of the bidiagonal matrix. On exit, *e* is destroyed.

ldu INTEGER. The leading dimension of arrays *u*, *vt*, *difl*, *difr*, *poles*, *givnum*, and *z*. $ldu \geq n$.

ldgcol INTEGER. The leading dimension of arrays *givcol* and *perm*. $ldgcol \geq n$.

work REAL for slasda
DOUBLE PRECISION for dlasda.
Workspace array, DIMENSION ($6n + (smlsiz+1)^2$).

iwork INTEGER.
Workspace array, *Dimension* must be at least $(7n)$.

Output Parameters

d On exit *d*, if *info* = 0, contains the singular values of the bidiagonal matrix.

u REAL for slasda
DOUBLE PRECISION for dlasda.
Array, DIMENSION (*ldu*, *smlsiz*) if *icompq* = 1.
Not referenced if *icompq* = 0.
If *icompq* = 1, on exit, *u* contains the left singular vector matrices of all subproblems at the bottom level.

vt REAL for slasda
DOUBLE PRECISION for dlasda.
Array, DIMENSION (*ldu*, *smlsiz+1*) if *icompq* = 1, and not referenced if *icompq* = 0. If *icompq* = 1, on exit, *vt* contains the right singular vector matrices of all subproblems at the bottom level.

<i>k</i>	INTEGER. Array, DIMENSION (<i>n</i>) if <i>icompg</i> = 1 and DIMENSION (1) if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>k</i>(<i>i</i>) is the dimension of the <i>i</i>-th secular equation on the computation tree.
<i>difl</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>ldu</i>, <i>nlvl</i>), where <i>nlvl</i> = floor(log₂(<i>n</i>/<i>smlsiz</i>)).
<i>difr</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>ldu</i>, 2 <i>nlvl</i>) if <i>icompg</i> = 1 and DIMENSION (<i>n</i>) if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>difl</i>(1:<i>n</i>, <i>i</i>) and <i>difr</i>(1:<i>n</i>, 2<i>i</i> - 1) record distances between singular values on the <i>i</i>-th level and singular values on the (<i>i</i> - 1)-th level, and <i>difr</i>(1:<i>n</i>, 2<i>i</i>) contains the normalizing factors for the right singular vector matrix. See ?lasd8 for details.
<i>z</i>	REAL for slasda DOUBLE PRECISION for dlasda. Array, DIMENSION (<i>ldu</i>, <i>nlvl</i>) if <i>icompg</i> = 1 and DIMENSION (<i>n</i>) if <i>icompg</i> = 0. The first <i>k</i> elements of <i>z</i>(1, <i>i</i>) contain the components of the deflation-adjusted updating row vector for subproblems on the <i>i</i>-th level.
<i>poles</i>	REAL for slasda DOUBLE PRECISION for dlasda Array, DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>poles</i>(1, 2<i>i</i> - 1) and <i>poles</i>(1, 2<i>i</i>) contain the new and old singular values involved in the secular equations on the <i>i</i>-th level.
<i>givptr</i>	INTEGER. Array, DIMENSION (<i>n</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>givptr</i>(<i>i</i>) records the number of Givens rotations performed on the <i>i</i>-th problem on the computation tree.

<i>givcol</i>	INTEGER . Array, DIMENSION (<i>ldgcol</i>, 2*<i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, for each <i>i</i>, <i>givcol</i>(1, 2 <i>i</i> - 1) and <i>givcol</i>(1, 2 <i>i</i>) record the locations of Givens rotations performed on the <i>i</i>-th level on the computation tree.
<i>perm</i>	INTEGER . Array, DIMENSION (<i>ldgcol</i>, <i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, <i>perm</i> (1, <i>i</i>) records permutations done on the <i>i</i>-th level of the computation tree.
<i>givnum</i>	REAL for <i>slasda</i> DOUBLE PRECISION for <i>dlasda</i>. Array DIMENSION (<i>ldu</i>, 2*<i>nlvl</i>) if <i>icompg</i> = 1, and not referenced if <i>icompg</i> = 0. If <i>icompg</i> = 1, on exit, for each <i>i</i>, <i>givnum</i>(1, 2 <i>i</i> - 1) and <i>givnum</i>(1, 2 <i>i</i>) record the <i>c</i>- and <i>s</i>-values of Givens rotations performed on the <i>i</i>-th level on the computation tree.
<i>c</i>	REAL for <i>slasda</i> DOUBLE PRECISION for <i>dlasda</i>. Array, DIMENSION (<i>n</i>) if <i>icompg</i> = 1, and DIMENSION (1) if <i>icompg</i> = 0. If <i>icompg</i> = 1 and the <i>i</i>-th subproblem is not square, on exit, <i>c</i>(<i>i</i>) contains the <i>c</i>-value of a Givens rotation related to the right null space of the <i>i</i>-th subproblem.
<i>s</i>	REAL for <i>slasda</i> DOUBLE PRECISION for <i>dlasda</i>. Array, DIMENSION (<i>n</i>) if <i>icompg</i> = 1, and DIMENSION (1) if <i>icompg</i> = 0. If <i>icompg</i> = 1 and the <i>i</i>-th subproblem is not square, on exit, <i>s</i>(<i>i</i>) contains the <i>s</i>-value of a Givens rotation related to the right null space of the <i>i</i>-th subproblem.
<i>info</i>	INTEGER. = 0: successful exit. < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value > 0: If <i>info</i> = 1, an singular value did not converge

?lasdq

Computes the SVD of a real bidiagonal matrix with diagonal d and off-diagonal e . Used by ?bdsdc.

Syntax

```
call slasdq( uplo, sqre, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc,
            work, info )
```

```
call dlasdq( uplo, sqre, n, ncvt, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc,
            work, info )
```

Description

The routine ?lasdq computes the singular value decomposition (SVD) of a real (upper or lower) bidiagonal matrix with diagonal d and off-diagonal e , accumulating the transformations if desired. If B is the input bidiagonal matrix, the algorithm computes orthogonal matrices Q and P such that $B = Q^T S P^T$. The singular values s are overwritten on d .

The input matrix U is changed to $U^* Q$ if desired.

The input matrix VT is changed to $P^T VT$ if desired.

The input matrix C is changed to $Q^T C$ if desired.

Input Parameters

<i>uplo</i>	CHARACTER*1. On entry, <i>uplo</i> specifies whether the input bidiagonal matrix is upper or lower bidiagonal. If <i>uplo</i> = 'U' or 'u', B is upper bidiagonal; If <i>uplo</i> = 'L' or 'l', B is lower bidiagonal.
<i>sqre</i>	INTEGER. = 0: then the input matrix is n -by- n . = 1: then the input matrix is n -by- $(n+1)$ if <i>uplu</i> = 'U' and $(n+1)$ -by- n if <i>uplu</i> = 'L'. The bidiagonal matrix has $n = n_l + n_r + 1$ rows and $m = n + sqre \geq n$ columns.
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the number of rows and columns in the matrix. <i>n</i> must be at least 0.

<i>ncvt</i>	INTEGER. On entry, <i>ncvt</i> specifies the number of columns of the matrix <i>VT</i> . <i>ncvt</i> must be at least 0.
<i>nru</i>	INTEGER. On entry, <i>nru</i> specifies the number of rows of the matrix <i>U</i> . <i>nru</i> must be at least 0.
<i>ncc</i>	INTEGER. On entry, <i>ncc</i> specifies the number of columns of the matrix <i>C</i> . <i>ncc</i> must be at least 0.
<i>d</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION (<i>n</i>). On entry, <i>d</i> contains the diagonal entries of the bidiagonal matrix.
<i>e</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION is (<i>n</i> -1) if <i>sqre</i> = 0 and <i>n</i> if <i>sqre</i> = 1. On entry, the entries of <i>e</i> contain the off-diagonal entries of the bidiagonal matrix.
<i>vt</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION (<i>ldvt</i> , <i>ncvt</i>). On entry, contains a matrix which on exit has been premultiplied by P^T , dimension <i>n</i> -by- <i>ncvt</i> if <i>sqre</i> = 0 and (<i>n</i> +1)-by- <i>ncvt</i> if <i>sqre</i> = 1 (not referenced if <i>ncvt</i> =0).
<i>ldvt</i>	INTEGER. On entry, <i>ldvt</i> specifies the leading dimension of <i>vt</i> as declared in the calling (sub) program. <i>ldvt</i> must be at least 1. If <i>ncvt</i> is nonzero, <i>ldvt</i> must also be at least <i>n</i> .
<i>u</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> . Array, DIMENSION (<i>ldu</i> , <i>n</i>). On entry, contains a matrix which on exit has been postmultiplied by <i>Q</i> , dimension <i>nru</i> -by- <i>n</i> if <i>sqre</i> = 0 and <i>nru</i> -by-(<i>n</i> +1) if <i>sqre</i> = 1 (not referenced if <i>nru</i> =0).
<i>ldu</i>	INTEGER. On entry, <i>ldu</i> specifies the leading dimension of <i>u</i> as declared in the calling (sub) program. <i>ldu</i> must be at least $\max(1, \text{ } nru \text{ })$.
<i>c</i>	REAL for <i>slasdq</i> DOUBLE PRECISION for <i>dlasdq</i> .

	Array, DIMENSION (<i>ldc</i> , <i>ncc</i>). On entry, contains an <i>n</i> -by- <i>ncc</i> matrix which on exit has been premultiplied by Q' , dimension <i>n</i> -by- <i>ncc</i> if <i>scre</i> = 0 and (<i>n</i> +1)-by- <i>ncc</i> if <i>scre</i> = 1 (not referenced if <i>ncc</i> =0).
<i>ldc</i>	INTEGER. On entry, <i>ldc</i> specifies the leading dimension of <i>c</i> as declared in the calling (sub) program. <i>ldc</i> must be at least 1. If <i>ncc</i> is non-zero, <i>ldc</i> must also be at least <i>n</i> .
<i>work</i>	REAL for slasdq DOUBLE PRECISION for dlasdq. Array, DIMENSION (4 <i>n</i>). This is a workspace array. Only referenced if one of <i>ncvt</i> , <i>nru</i> , or <i>ncc</i> is nonzero, and if <i>n</i> is at least 2.

Output Parameters

<i>d</i>	On normal exit, <i>d</i> contains the singular values in ascending order.
<i>e</i>	On normal exit, <i>e</i> will contain 0. If the algorithm does not converge, <i>d</i> and <i>e</i> will contain the diagonal and superdiagonal entries of a bidiagonal matrix orthogonally equivalent to the one given as input.
<i>vt</i>	On exit, the matrix has been premultiplied by P' .
<i>u</i>	On exit, the matrix has been postmultiplied by Q .
<i>c</i>	On exit, the matrix has been premultiplied by Q' .
<i>info</i>	INTEGER. On exit, a value of 0 indicates a successful exit. If <i>info</i> < 0, argument number - <i>info</i> is illegal. If <i>info</i> > 0, the algorithm did not converge, and <i>info</i> specifies how many superdiagonals did not converge.

?lasdt

Creates a tree of subproblems for bidiagonal divide and conquer. Used by ?bdsdc.

Syntax

```
call slasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
```

```
call dlasdt( n, lvl, nd, inode, ndiml, ndimr, msub )
```

Description

The routine creates a tree of subproblems for bidiagonal divide and conquer.

Input Parameters

<i>n</i>	INTEGER. On entry, the number of diagonal elements of the bidiagonal matrix.
<i>msub</i>	INTEGER. On entry, the maximum row dimension each subproblem at the bottom of the tree can be of.

Output Parameters

<i>lvl</i>	INTEGER. On exit, the number of levels on the computation tree.
<i>nd</i>	INTEGER. On exit, the number of nodes on the tree.
<i>inode</i>	INTEGER. Array, DIMENSION (<i>n</i>). On exit, centers of subproblems.
<i>ndiml</i>	INTEGER . Array, DIMENSION (<i>n</i>). On exit, row dimensions of left children.
<i>ndimr</i>	INTEGER . Array, DIMENSION (<i>n</i>). On exit, row dimensions of right children.

zlaset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```
call slaset( uplo, m, n, alpha, beta, a, lda )
call dlaset( uplo, m, n, alpha, beta, a, lda )
call claset( uplo, m, n, alpha, beta, a, lda )
call zlaset( uplo, m, n, alpha, beta, a, lda )
```

Description

The routine initializes an m -by- n matrix A to β on the diagonal and α on the off-diagonals.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies the part of the matrix A to be set. If <i>uplo</i> = 'U', upper triangular part is set; the strictly lower triangular part of A is not changed. If <i>uplo</i> = 'L': lower triangular part is set; the strictly upper triangular part of A is not changed. Otherwise: All of the matrix A is set.
<i>m</i>	INTEGER. The number of rows of the matrix A . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix A . $n \geq 0$.
<i>alpha, beta</i>	REAL for slaset DOUBLE PRECISION for dlaset COMPLEX for claset COMPLEX*16 for zlaset. The constants to which the off-diagonal and diagonal elements are to be set, respectively.
<i>a</i>	REAL for slaset DOUBLE PRECISION for dlaset COMPLEX for claset COMPLEX*16 for zlaset.

Array, DIMENSION (lda, n).
 On entry, the m -by- n matrix A .
 lda INTEGER. The leading dimension of the array a .
 $lda \geq \max(1, m)$.

Output Parameters

a On exit, the leading m -by- n submatrix of A is set as follows:
 if $uplo = 'U'$, $A(i, j) = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$,
 if $uplo = 'L'$, $A(i, j) = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$,
 otherwise, $A(i, j) = \alpha, 1 \leq i \leq m, 1 \leq j \leq n, i \neq j$,
 and, for all $uplo$, $A(i, i) = \beta, 1 \leq i \leq \min(m, n)$.

?lasq1

*Computes the singular values of a real square
 bidiagonal matrix. Used by ?bdsqr.*

Syntax

```
call slasq1( n, d, e, work, info )
call dlasq1( n, d, e, work, info )
```

Description

The routine ?lasq1 computes the singular values of a real n -by- n bidiagonal matrix with diagonal d and off-diagonal e . The singular values are computed to high relative accuracy, in the absence of denormalization, underflow and overflow.

Input Parameters

n INTEGER. The number of rows and columns in the matrix. $n \geq 0$.
 d REAL for slasq1
 DOUBLE PRECISION for dlasq1.
 Array, DIMENSION (n).
 On entry, d contains the diagonal elements of the bidiagonal matrix whose SVD is desired.

<i>e</i>	REAL for <code>slasq1</code> DOUBLE PRECISION for <code>dlasq1</code>. Array, DIMENSION (<i>n</i>). On entry, elements <code>e(1:n-1)</code> contain the off-diagonal elements of the bidiagonal matrix whose <i>SVD</i> is desired.
<i>work</i>	REAL for <code>slasq1</code> DOUBLE PRECISION for <code>dlasq1</code>. Workspace array, DIMENSION ($4n$).

Output Parameters

<i>d</i>	On normal exit, <i>d</i> contains the singular values in decreasing order.
<i>e</i>	On exit, <i>e</i> is overwritten.
<i>info</i>	INTEGER. = 0: successful exit; < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value; > 0: the algorithm failed: = 1, a split was marked by a positive value in <i>e</i>; = 2, current block of <i>z</i> not diagonalized after $30n$ iterations (in inner while loop); = 3, termination criterion of outer while loop not met (program created more than <i>n</i> unreduced blocks).

?lasq2

*Computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the `qd` array *z* to high relative accuracy. Used by `?bdsqr` and `?stegr`.*

Syntax

```
call slasq2( n, z, info )
call dlasq2( n, z, info )
```

Description

The routine `?lasq2` computes all the eigenvalues of the symmetric positive definite tridiagonal matrix associated with the *qd* array *z* to high relative accuracy, in the absence of denormalization, underflow and overflow.

To see the relation of *z* to the tridiagonal matrix, let *L* be a unit lower bidiagonal matrix with subdiagonals *z*(2,4,6,...) and let *U* be an upper bidiagonal matrix with 1's above and diagonal *z*(1,3,5,...). The tridiagonal is *LU* or, if you prefer, the symmetric tridiagonal to which it is similar.

Input Parameters

n INTEGER. The number of rows and columns in the matrix.
 $n \geq 0$.

z REAL for `slasq2`
 DOUBLE PRECISION for `dlasq2`.
 Array, DIMENSION (4 * *n*).
 On entry, *z* holds the *qd* array.

Output Parameters

z On exit, entries 1 to *n* hold the eigenvalues in decreasing order, *z*(2*n*+1) holds the trace, and *z*(2*n*+2) holds the sum of the eigenvalues. If $n > 2$, then *z*(2*n*+3) holds the iteration count, *z*(2*n*+4) holds ndivs/n^2 , and *z*(2*n*+5) holds the percentage of shifts that failed.

info INTEGER.
 = 0: successful exit;
 < 0: if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*, if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+ *j*);
 > 0: the algorithm failed:
 = 1, a split was marked by a positive value in *e*;
 = 2, current block of *z* not diagonalized after 30**n* iterations (in inner while loop);
 = 3, termination criterion of outer while loop not met (program created more than *n* unreduced blocks).

Application Notes

The routine `?lasq2` defines a logical variable, `ieee`, which is `.TRUE.` on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs, and `.FALSE.` otherwise. This variable is passed to `?lazq3`.

?lasq3

Checks for deflation, computes a shift and calls `dqds`. Used by `?bdsqr`.

Syntax

```
call slasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee
)
call dlasq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee
)
```

Description

The routine `?lasq3` checks for deflation, computes a shift, and calls `dqds`. In case of failure, it changes shifts, and tries again until output is positive.

Input Parameters

<code>i0</code>	INTEGER. First index.
<code>n0</code>	INTEGER. Last index.
<code>z</code>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the <i>qd</i> array.
<code>pp</code>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<code>desig</code>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Lower order part of <i>sigma</i> .
<code>qmax</code>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Maximum value of <i>q</i> .
<code>ieee</code>	LOGICAL. Flag for ieee or non-ieee arithmetic (passed to <code>?lasq5</code>).

Output Parameters

<i>dmin</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Minimum value of <i>d</i> .
<i>sigma</i>	REAL for <code>slasq3</code> DOUBLE PRECISION for <code>dlasq3</code> . Sum of shifts used in current segment.
<i>desig</i>	Lower order part of <i>sigma</i> .
<i>nfail</i>	INTEGER. Number of times shift was too big.
<i>iter</i>	INTEGER. Number of iterations.
<i>ndiv</i>	INTEGER. Number of divisions.

?lasq4

*Computes an approximation to the smallest eigenvalue using values of *d* from the previous transform. Used by ?bdsqr.*

Syntax

```
call slasq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype
)
call dlasq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau, ttype
)
```

Description

The routine computes an approximation *tau* to the smallest eigenvalue using values of *d* from the previous transform.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq4</code> DOUBLE PRECISION for <code>dlasq4</code> . Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the <i>qd</i> array.

<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>n0in</i>	INTEGER. The value of <i>n0</i> at start of eigtest.
<i>dmin</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>).
<i>dmin2</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1).
<i>dn</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains <i>d</i> (<i>n</i>).
<i>dn1</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains <i>d</i> (<i>n</i> -1).
<i>dn2</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Contains <i>d</i> (<i>n</i> -2).

Output Parameters

<i>tau</i>	REAL for slasq4 DOUBLE PRECISION for dlasq4. Shift.
<i>ttype</i>	INTEGER. Shift type.

?lasq5

Computes one dqds transform in ping-pong form.
Used by ?bdsqr and ?stegr.

Syntax

```
call slasq5( i0, n0, z, pp, tau, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee )
call dlasq5( i0, n0, z, pp, tau, dmin, dmin1, dmin2, dn, dnm1, dnm2, ieee )
```

Description

The routine computes one dqds transform in ping-pong form: one version for ieee machines, another for non-ieee machines.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the qd array. <i>emin</i> is stored in <i>z</i> (4* <i>n0</i>) to avoid an extra argument.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>tau</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. This is the shift.
<i>ieee</i>	LOGICAL. Flag for IEEE or non-IEEE arithmetic.

Output Parameters

<i>dmin</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Minimum value of <i>d</i> .
<i>dmin1</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>).
<i>dmin2</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1).
<i>dn</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Contains <i>d</i> (<i>n0</i>), the last value of <i>d</i> .
<i>dnm1</i>	REAL for slasq5 DOUBLE PRECISION for dlasq5. Contains <i>d</i> (<i>n0</i> -1).
<i>dnm2</i>	REAL for slasq5

DOUBLE PRECISION for `dlasq5`. Contains $d(n0-2)$.

?lasq6

*Computes one dqd transform in ping-pong form.
Used by ?bdsqr and ?stegr.*

Syntax

```
call slasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
call dlasq6( i0, n0, z, pp, dmin, dmin1, dmin2, dn, dnm1, dnm2 )
```

Description

The routine ?lasq6 computes one dqd (shift equal to zero) transform in ping-pong form, with protection against underflow and overflow.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Array, DIMENSION (4 <i>n</i>). <i>z</i> holds the qd array. <i>emin</i> is stored in $z(4*n0)$ to avoid an extra argument.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.

Output Parameters

<i>dmin</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Minimum value of d .
<i>dmin1</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Minimum value of d , excluding $d(n0)$.
<i>dmin2</i>	REAL for <code>slasq6</code> DOUBLE PRECISION for <code>dlasq6</code> . Minimum value of d , excluding $d(n0)$ and $d(n0-1)$.
<i>dn</i>	REAL for <code>slasq6</code>

	DOUBLE PRECISION for dlasq6. Contains $d(n0)$, the last value of d .
$dnm1$	REAL for slasq6 DOUBLE PRECISION for dlasq6. Contains $d(n0-1)$.
$dnm2$	REAL for slasq6 DOUBLE PRECISION for dlasq6. Contains $d(n0-2)$.

?lasr

Applies a sequence of plane rotations to a general rectangular matrix.

Syntax

```
call slasr( side, pivot, direct, m, n, c, s, a, lda )
call dlasr( side, pivot, direct, m, n, c, s, a, lda )
call clasr( side, pivot, direct, m, n, c, s, a, lda )
call zlasr( side, pivot, direct, m, n, c, s, a, lda )
```

Description

The routine applies a sequence of plane rotations to a real/complex matrix A , from the left or the right.

$A := P^*A$, when $side = 'L'$ (Left-hand side)

$A := A^*P$, when $side = 'R'$ (Right-hand side)

where P is an orthogonal matrix consisting of a sequence of plane rotations with $z = m$ when $side = 'L'$ and $z = n$ when $side = 'R'$.

When $direct = 'F'$ (Forward sequence), then

$$P = P(z-1) * \dots * P(2) * P(1),$$

and when $direct = 'B'$ (Backward sequence), then

$$P = P(1) * P(2) * \dots * P(z-1),$$

where $P(k)$ is a plane rotation matrix defined by the 2-by-2 plane rotation:

$$R(k) = \begin{bmatrix} c(k) & s(k) \\ -s(k) & c(k) \end{bmatrix}$$

When $pivot = 'V'$ (Variable pivot), the rotation is performed for the plane $(k, k + 1)$, that is, $P(k)$ has the form

$$P(k) = \begin{bmatrix} 1 & & & & & \\ & \dots & & & & \\ & & 1 & & & \\ & & & c(k) & s(k) & \\ & & & -s(k) & c(k) & \\ & & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears as a rank-2 modification to the identity matrix in rows and columns k and $k+1$.

When $pivot = 'T'$ (Top pivot), the rotation is performed for the plane $(1, k+1)$, so $P(k)$ has the form

$$P(k) = \begin{bmatrix} c(k) & & & s(k) & & \\ & 1 & & & & \\ & & \dots & & & \\ & & & 1 & & \\ -s(k) & & & & c(k) & \\ & & & & & 1 \\ & & & & & \dots \\ & & & & & & 1 \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and $k+1$.

Similarly, when $pivot = 'B'$ (Bottom pivot), the rotation is performed for the plane (k, z) , giving $P(k)$ the form

$$P(k) = \begin{bmatrix} 1 & & & & & \\ & \dots & & & & \\ & & 1 & & & \\ & & & c(k) & & s(k) \\ & & & & 1 & \\ & & & & & \dots \\ & & & & & & 1 \\ & & & -s(k) & & & c(k) \end{bmatrix}$$

where $R(k)$ appears in rows and columns k and z . The rotations are performed without ever forming $P(k)$ explicitly.

Input Parameters

side CHARACTER*1. Specifies whether the plane rotation matrix P is applied to A on the left or the right.

	= 'L': left, compute $A := P^*A$ = 'R': right, compute $A := A^*P$
<i>direct</i>	CHARACTER*1. Specifies whether P is a forward or backward sequence of plane rotations. = 'F': forward, $P = P(z-1) * \dots * P(2) * P(1)$ = 'B': backward, $P = P(1) * P(2) * \dots * P(z-1)$
<i>pivot</i>	CHARACTER*1. Specifies the plane for which $P(k)$ is a plane rotation matrix. = 'V': Variable pivot, the plane $(k, k+1)$ = 'T': Top pivot, the plane $(1, k+1)$ = 'B': Bottom pivot, the plane (k, z)
<i>m</i>	INTEGER. The number of rows of the matrix A. If $m \leq 1$, an immediate return is effected.
<i>n</i>	INTEGER. The number of columns of the matrix A. If $n \leq 1$, an immediate return is effected.
<i>c, s</i>	REAL for slasr/clasr DOUBLE PRECISION for dlasr/zlasr. Arrays, DIMENSION $(m-1)$ if <i>side</i> = 'L', $(n-1)$ if <i>side</i> = 'R' . $c(k)$ and $s(k)$ contain the cosine and sine of the plane rotations respectively that define the 2-by-2 plane rotation part ($R(k)$) of the $P(k)$ matrix as described above in <i>Description</i>.
<i>a</i>	REAL for slasr DOUBLE PRECISION for dlasr COMPLEX for clasr COMPLEX*16 for zlasr. Array, DIMENSION (lda, n). The m-by-n matrix A.
<i>lda</i>	INTEGER. The leading dimension of the array a. $lda \geq \max(1, m)$.

Output Parameters

a On exit, *A* is overwritten by P^*A if *side* = 'R', or by A^*P if *side* = 'L'.

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt( id, n, d, info )
```

```
call dlasrt( id, n, d, info )
```

Description

The routine ?lasrt sorts the numbers in *d* in increasing order (if *id* = 'I') or in decreasing order (if *id* = 'D'). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of *stack* limits *n* to about 2^{32} .

Input Parameters

id CHARACTER*1.
= 'I': sort *d* in increasing order;
= 'D': sort *d* in decreasing order.

n INTEGER. The length of the array *d*.

d REAL for slasrt
DOUBLE PRECISION for dlasrt.
On entry, the array to be sorted.

Output Parameters

d On exit, *d* has been sorted into increasing order
($d(1) \leq \dots \leq d(n)$) or into decreasing order
($d(1) \geq \dots \geq d(n)$), depending on *id*.

info INTEGER.
= 0: successful exit
< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call slassq( n, x, incx, scale, sumsq )
call dlassq( n, x, incx, scale, sumsq )
call classq( n, x, incx, scale, sumsq )
call zlassq( n, x, incx, scale, sumsq )
```

Description

The real routines `slassq`/`dlassq` return the values `scl` and `smSQ` such that

$$scl^2 * smSQ = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = x(1 + (i - 1) * incx)$.

The value of `sumsq` is assumed to be non-negative and `scl` returns the value

$$scl = \max(scale, \text{abs}(x(i))).$$

Values `scale` and `sumsq` must be supplied in `scale` and `sumsq`, and `scl` and `smSQ` are overwritten on `scale` and `sumsq`, respectively.

The complex routines `classq`/`zlassq` return the values `scl` and `ssq` such that

$$scl^2 * ssq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = \text{abs}(x(1 + (i - 1) * incx))$.

The value of `sumsq` is assumed to be at least unity and the value of `ssq` will then satisfy 1.0

$$\leq ssq \leq sumsq + 2n$$

`scale` is assumed to be non-negative and `scl` returns the value

$$scl = \max(scale, \text{abs}(\text{real}(x(i))), \text{abs}(\text{aimag}(x(i)))).$$

Values `scale` and `sumsq` must be supplied in `scale` and `sumsq`, and `scl` and `ssq` are overwritten on `scale` and `sumsq`, respectively.

All routines `?lassq` make only one pass through the vector `x`.

Input Parameters

<i>n</i>	INTEGER. The number of elements to be used from the vector <i>x</i> .
<i>x</i>	REAL for <i>slassq</i> DOUBLE PRECISION for <i>dlassq</i> COMPLEX for <i>classq</i> COMPLEX*16 for <i>zlassq</i> . The vector for which a scaled sum of squares is computed: $x(i) = x(1+(i-1)*incx), 1 \leq i \leq n$.
<i>incx</i>	INTEGER. The increment between successive values of the vector <i>x</i> . <i>incx</i> > 0.
<i>scale</i>	REAL for <i>slassq/classq</i> DOUBLE PRECISION for <i>dlassq/zlassq</i> . On entry, the value <i>scale</i> in the equation above.
<i>sumsq</i>	REAL for <i>slassq/classq</i> DOUBLE PRECISION for <i>dlassq/zlassq</i> . On entry, the value <i>sumsq</i> in the equation above.

Output Parameters

<i>scale</i>	On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares.
<i>sumsq</i>	For real flavors: On exit, <i>sumsq</i> is overwritten with the value <i>sumsq</i> in the equation above. For complex flavors: On exit, <i>sumsq</i> is overwritten with the value <i>ssq</i> in the equation above.

?lasv2

Computes the singular value decomposition of a 2-by-2 triangular matrix.

Syntax

```
call slasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
call dlasv2( f, g, h, ssmin, ssmax, snr, csr, snl, csl )
```

Description

The routine ?lasv2 computes the singular value decomposition of a 2-by-2 triangular matrix

$$\begin{bmatrix} f & g \\ 0 & h \end{bmatrix}$$

On return, $\text{abs}(ssmax)$ is the larger singular value, $\text{abs}(ssmin)$ is the smaller singular value, and (csl, snl) and (csr, snr) are the left and right singular vectors for $\text{abs}(ssmax)$, giving the decomposition

$$\begin{bmatrix} csl & snl \\ -snl & csl \end{bmatrix} \begin{bmatrix} f & g \\ 0 & h \end{bmatrix} \begin{bmatrix} csr & -snr \\ snr & csr \end{bmatrix} = \begin{bmatrix} ssmax & 0 \\ 0 & ssmin \end{bmatrix}$$

Input Parameters

f, g, h	REAL for slasv2 DOUBLE PRECISION for dlasv2. The (1,1), (1,2) and (2,2) elements of the 2-by-2 matrix, respectively.

Output Parameters

$ssmin, ssmax$	REAL for slasv2 DOUBLE PRECISION for dlasv2.

`abs(ssmin)` and `abs(ssmax)` is the smaller and the larger singular value, respectively.

snl, csl REAL for `slasv2`
 DOUBLE PRECISION for `dlasv2`.
 The vector (*csl, snl*) is a unit left singular vector for the singular value `abs(ssmax)`.

snr, csr REAL for `slasv2`
 DOUBLE PRECISION for `dlasv2`.
 The vector (*csr, snr*) is a unit right singular vector for the singular value `abs(ssmax)`.

Application Notes

Any input parameter may be aliased with any output parameter.

Barring over/underflow and assuming a guard digit in subtraction, all output quantities are correct to within a few units in the last place (ulps).

In ieee arithmetic, the code works correctly if one matrix element is infinite. Overflow will not occur unless the largest singular value itself overflows or is within a few ulps of overflow. (On machines with partial overflow, like the Cray, overflow may occur if the largest singular value is within a factor of 2 of overflow.) Underflow is harmless if underflow is gradual. Otherwise, results may correspond to a matrix modified by perturbations of size near the underflow threshold.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call slaswp( n, a, lda, k1, k2, ipiv, incx )
call dlaswp( n, a, lda, k1, k2, ipiv, incx )
call claswp( n, a, lda, k1, k2, ipiv, incx )
call zlaswp( n, a, lda, k1, k2, ipiv, incx )
```

Description

The routine performs a series of row interchanges on the matrix *A*. One row interchange is initiated for each of rows *k1* through *k2* of *A*.

Input Parameters

<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> .
<i>a</i>	REAL for <i>slaswp</i> DOUBLE PRECISION for <i>dlaswp</i> COMPLEX for <i>claswp</i> COMPLEX*16 for <i>zlaswp</i> . Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the matrix of column dimension <i>n</i> to which the row interchanges will be applied.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> .
<i>k1</i>	INTEGER. The first element of <i>ipiv</i> for which a row interchange will be done.
<i>k2</i>	INTEGER. The last element of <i>ipiv</i> for which a row interchange will be done.
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>k2</i> * <i>incx</i>). The vector of pivot indices. Only the elements in positions <i>k1</i> through <i>k2</i> of <i>ipiv</i> are accessed. <i>ipiv</i> (<i>k</i>) = <i>l</i> implies rows <i>k</i> and <i>l</i> are to be interchanged.
<i>incx</i>	INTEGER. The increment between successive values of <i>ipiv</i> . If <i>ipiv</i> is negative, the pivots are applied in reverse order.

Output Parameters

<i>a</i>	On exit, the permuted matrix.

?lasy2

Solves the Sylvester matrix equation where the matrices are of order 1 or 2.

Syntax

```
call slasy2( ltranl, ltranr, isgn, n1, n2, tl, ldtl, tr, ldtr, b, ldb, scale,
x, ldx, xnorm, info )
```

```
call dlasy2( ltranl, ltranr, isgn, n1, n2, tl, ldtl, tr, ldtr, b, ldb, scale,
x, ldx, xnorm, info )
```

Description

The routine solves for the $n1$ -by- $n2$ matrix X , $1 \leq n1, n2 \leq 2$, in

$$\text{op}(TL) * X + \text{isgn} * X * \text{op}(TR) = \text{scale} * B,$$

where

TL is $n1$ -by- $n1$,

TR is $n2$ -by- $n2$,

B is $n1$ -by- $n2$,

and $\text{isgn} = 1$ or -1 . $\text{op}(T) = T$ or T^T , where T^T denotes the transpose of T .

Input Parameters

<i>ltranl</i>	LOGICAL. On entry, <i>ltranl</i> specifies the $\text{op}(TL)$: = <code>.FALSE.</code> , $\text{op}(TL) = TL$, = <code>.TRUE.</code> , $\text{op}(TL) = (TL)^T$.
<i>ltranr</i>	LOGICAL. On entry, <i>ltranr</i> specifies the $\text{op}(TR)$: = <code>.FALSE.</code> , $\text{op}(TR) = TR$, = <code>.TRUE.</code> , $\text{op}(TR) = (TR)^T$.
<i>isgn</i>	INTEGER. On entry, <i>isgn</i> specifies the sign of the equation as described before. <i>isgn</i> may only be 1 or -1.
<i>n1</i>	INTEGER. On entry, <i>n1</i> specifies the order of matrix TL . <i>n1</i> may only be 0, 1 or 2.

<i>n2</i>	INTEGER. On entry, <i>n2</i> specifies the order of matrix <i>TR</i> . <i>n2</i> may only be 0, 1 or 2.
<i>t1</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldt1</i> ,2). On entry, <i>t1</i> contains an <i>n1</i> -by- <i>n1</i> matrix <i>TL</i> .
<i>ldt1</i>	INTEGER. The leading dimension of the matrix <i>TL</i> . $ldt1 \geq \max(1, n1)$.
<i>tr</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldtr</i> ,2). On entry, <i>tr</i> contains an <i>n2</i> -by- <i>n2</i> matrix <i>TR</i> .
<i>ldtr</i>	INTEGER. The leading dimension of the matrix <i>TR</i> . $ldtr \geq \max(1, n2)$.
<i>b</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldb</i> ,2). On entry, the <i>n1</i> -by- <i>n2</i> matrix <i>B</i> contains the right-hand side of the equation.
<i>ldb</i>	INTEGER. The leading dimension of the matrix <i>B</i> . $ldb \geq \max(1, n1)$.
<i>ldx</i>	INTEGER. The leading dimension of the output matrix <i>X</i> . $ldx \geq \max(1, n1)$.

Output Parameters

<i>scale</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. On exit, <i>scale</i> contains the scale factor. <i>scale</i> is chosen less than or equal to 1 to prevent the solution overflowing.
<i>x</i>	REAL for slasy2 DOUBLE PRECISION for dlasy2. Array, DIMENSION (<i>ldx</i> ,2). On exit, <i>x</i> contains the <i>n1</i> -by- <i>n2</i> solution.
<i>xnorm</i>	REAL for slasy2

info DOUBLE PRECISION for `dlasy2`.
 On exit, *xnorm* is the infinity-norm of the solution.
 INTEGER. On exit, *info* is set to 0: successful exit. 1: *TL* and *TR* have too close eigenvalues, so *TL* or *TR* is perturbed to get a nonsingular equation.

NOTE. For higher speed, this routine does not check the inputs for errors.

?lasyf

Computes a partial factorization of a real/complex symmetric matrix, using the diagonal pivoting method.

Syntax

```
call slasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call dlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call clasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlasyf( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Description

The routine `?lasyf` computes a partial factorization of a real/complex symmetric matrix *A* using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{12}' \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}' & U_{12}' \end{bmatrix} \text{ if } uplo = 'U', \text{ or}$$

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{12}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } uplo = 'L'$$

where the order of *D* is at most *nb*.

The actual order is returned in the argument *kb*, and is either *nb* or *nb-1*, or *n* if $n \leq nb$.

This is an auxiliary routine called by `?sytrf`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if *uplo* = 'U') or A_{22} (if *uplo* = 'L').

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>nb</i>	INTEGER. The maximum number of columns of the matrix <i>A</i> that should be factored. <i>nb</i> should be at least 2 to allow for 2-by-2 pivot blocks.
<i>a</i>	REAL for <code>slasyf</code> DOUBLE PRECISION for <code>dlasyf</code> COMPLEX for <code>clasyf</code> COMPLEX*16 for <code>zlasyf</code> . Array, DIMENSION (<i>lda</i> , <i>n</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> , and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> , and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.
<i>w</i>	REAL for <code>slasyf</code> DOUBLE PRECISION for <code>dlasyf</code> COMPLEX for <code>clasyf</code> COMPLEX*16 for <code>zlasyf</code> . Workspace array, DIMENSION (<i>ldw</i> , <i>nb</i>).
<i>ldw</i>	INTEGER. The leading dimension of the array <i>w</i> . $ldw \geq \max(1, n)$.

Output Parameters

<i>kb</i>	INTEGER. The number of columns of <i>A</i> that were actually factored <i>kb</i> is either <i>nb</i> -1 or <i>nb</i> , or <i>n</i> if $n \leq nb$.
<i>a</i>	On exit, <i>a</i> contains details of the partial factorization.
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). Details of the interchanges and the block structure of <i>D</i> . If <i>uplo</i> = 'U', only the last <i>kb</i> elements of <i>ipiv</i> are set; if <i>uplo</i> = 'L', only the first <i>kb</i> elements are set. If <i>ipiv</i> (<i>k</i>) > 0, then rows and columns <i>k</i> and <i>ipiv</i> (<i>k</i>) were interchanged and <i>D</i> (<i>k</i> , <i>k</i>) is a 1-by-1 diagonal block. If <i>uplo</i> = 'U' and <i>ipiv</i> (<i>k</i>) = <i>ipiv</i> (<i>k</i> -1) < 0, then rows and columns <i>k</i> -1 and - <i>ipiv</i> (<i>k</i>) were interchanged and <i>D</i> (<i>k</i> -1: <i>k</i> , <i>k</i> -1: <i>k</i>) is a 2-by-2 diagonal block. If <i>uplo</i> = 'L' and <i>ipiv</i> (<i>k</i>) = <i>ipiv</i> (<i>k</i> +1) < 0, then rows and columns <i>k</i> +1 and - <i>ipiv</i> (<i>k</i>) were interchanged and <i>D</i> (<i>k</i> : <i>k</i> +1, <i>k</i> : <i>k</i> +1) is a 2-by-2 diagonal block.
<i>info</i>	INTEGER. = 0: successful exit > 0: if <i>info</i> = <i>k</i> , <i>D</i> (<i>k</i> , <i>k</i>) is exactly zero. The factorization has been completed, but the block diagonal matrix <i>D</i> is exactly singular.

?lahef

Computes a partial factorization of a complex Hermitian indefinite matrix, using the diagonal pivoting method.

Syntax

```
call clahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
call zlahef( uplo, n, nb, kb, a, lda, ipiv, w, ldw, info )
```

Description

The routine ?lahef computes a partial factorization of a complex Hermitian matrix *A*, using the Bunch-Kaufman diagonal pivoting method. The partial factorization has the form:

$$A = \begin{bmatrix} I & U_{12} \\ 0 & U_{12}' \end{bmatrix} \begin{bmatrix} A_{11} & 0 \\ 0 & D \end{bmatrix} \begin{bmatrix} I & 0 \\ U_{12}' & U_{12}' \end{bmatrix} \text{ if } uplo = 'U', \text{ or}$$

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{21} & I \end{bmatrix} \begin{bmatrix} D & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} L_{12}' & L_{21}' \\ 0 & I \end{bmatrix} \text{ if } uplo = 'L'$$

where the order of D is at most nb .

The actual order is returned in the argument kb , and is either nb or $nb-1$, or n if $n \leq nb$.

Note that U' denotes the conjugate transpose of U .

This is an auxiliary routine called by `?hetrf`. It uses blocked code (calling Level 3 BLAS) to update the submatrix A_{11} (if $uplo = 'U'$) or A_{22} (if $uplo = 'L'$).

Input Parameters

$uplo$	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: = 'U': upper triangular = 'L': lower triangular
n	INTEGER. The order of the matrix A . $n \geq 0$.
nb	INTEGER. The maximum number of columns of the matrix A that should be factored. nb should be at least 2 to allow for 2-by-2 pivot blocks.
a	COMPLEX for <code>claherf</code> COMPLEX*16 for <code>zlaherf</code> . Array, DIMENSION (lda , n). On entry, the Hermitian matrix A . If $uplo = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

lda INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

w COMPLEX for `clahef`
COMPLEX*16 for `zlahef`.
Workspace array, DIMENSION (ldw, nb).

ldw INTEGER. The leading dimension of the array w . $ldw \geq \max(1, n)$.

Output Parameters

kb INTEGER. The number of columns of A that were actually factored kb is either $nb-1$ or nb , or n if $n \leq nb$.

a On exit, A contains details of the partial factorization.

ipiv INTEGER.
Array, DIMENSION (n). Details of the interchanges and the block structure of D .
If $uplo = 'U'$, only the last kb elements of $ipiv$ are set;
if $uplo = 'L'$, only the first kb elements are set.
If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ are interchanged and $D(k, k)$ is a 1-by-1 diagonal block.
If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ are interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.
If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ are interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info INTEGER.
= 0: successful exit
> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular.

?latbs

Solves a triangular banded system of equations.

Syntax

```
call slatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm,
info )
```

```
call dlatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm,
info )
```

```
call clatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm,
info )
```

```
call zlatbs( uplo, trans, diag, normin, n, kd, ab, ldab, x, scale, cnorm,
info )
```

Description

The routine solves one of the triangular systems

$A*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular band matrix. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine ?tbsv is called. If the matrix A is singular ($A(j, j)=0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': upper triangular = 'L': lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^H*x = s*b$ (conjugate transpose)

<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is unit triangular = 'N': non-unit triangular = 'U': unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> is set. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms is computed and stored in <i>cnorm</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.
<i>kd</i>	INTEGER. The number of subdiagonals or superdiagonals in the triangular matrix <i>A</i>. $kb \geq 0$.
<i>ab</i>	REAL for slatbs DOUBLE PRECISION for dlatbs COMPLEX for clatbs COMPLEX*16 for zlatbs. Array, DIMENSION (<i>ldab</i>, <i>n</i>). The upper or lower triangular band matrix <i>A</i>, stored in the first <i>kb</i>+1 rows of the array. The <i>j</i>-th column of <i>A</i> is stored in the <i>j</i>-th column of the array <i>ab</i> as follows: if <i>uplo</i> = 'U', $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if <i>uplo</i> = 'L', $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i>. $ldab \geq kb+1$.
<i>x</i>	REAL for slatbs DOUBLE PRECISION for dlatbs COMPLEX for clatbs COMPLEX*16 for zlatbs. Array, DIMENSION (<i>n</i>). On entry, the right hand side <i>b</i> of the triangular system.
<i>cnorm</i>	REAL for slatbs/clatbs DOUBLE PRECISION for dlatbs/zlatbs. Array, DIMENSION (<i>n</i>).

If `NORMIN = 'Y'`, `cnorm` is an input argument and `cnorm(j)` contains the norm of the off-diagonal part of the j -th column of A .

If `trans = 'N'`, `cnorm(j)` must be greater than or equal to the infinity-norm, and if `trans = 'T'` or `'C'`, `cnorm(j)` must be greater than or equal to the 1-norm.

Output Parameters

<code>scale</code>	REAL for <code>slatbs/clatbs</code> DOUBLE PRECISION for <code>dlatbs/zlatbs</code>. The scaling factor s for the triangular system as described above. If <code>scale = 0</code>, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $Ax = 0$.
<code>cnorm</code>	If <code>normin = 'N'</code>, <code>cnorm</code> is an output argument and <code>cnorm(j)</code> returns the 1-norm of the off-diagonal part of the j-th column of A.
<code>info</code>	INTEGER. = 0: successful exit < 0: if <code>info = -k</code>, the k-th argument had an illegal value

?latdf

Uses the LU factorization of the n -by- n matrix computed by ?getc2 and computes a contribution to the reciprocal Dif-estimate.

Syntax

```
call slatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call dlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call clatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
call zlatdf( ijob, n, z, ldz, rhs, rdsum, rdscal, ipiv, jpiv )
```

Description

The routine `?latdf` uses the LU factorization of the n -by- n matrix Z computed by `?getc2` and computes a contribution to the reciprocal Dif-estimate by solving $Z^*x = b$ for x , and choosing the right-hand side b such that the norm of x is as large as possible. On entry $rhs = b$ holds the contribution from earlier solved sub-systems, and on return $rhs = x$.

The factorization of Z returned by `?getc2` has the form $Z = P^*L^*U^*Q$, where P and Q are permutation matrices. L is lower triangular with unit diagonal elements and U is upper triangular.

Input Parameters

ijob INTEGER.
ijob = 2: First compute an approximative null-vector e of Z using `?gecon`, e is normalized, and solve for $Z^*x = \pm e - f$ with the sign giving the greater value of 2-norm(x). This option is about 5 times as expensive as default.
ijob $\neq$ 2 (default): Local look ahead strategy where all entries of the right-hand side b is chosen as either +1 or -1.
 .

n INTEGER. The number of columns of the matrix Z .

z REAL for `slatdf/clatdf`
 DOUBLE PRECISION for `dlatdf/zlatdf`.
 Array, DIMENSION (*ldz*, *n*)
 On entry, the LU part of the factorization of the n -by- n matrix Z computed by `?getc2`: $Z = P^*L^*U^*Q$.

ldz INTEGER. The leading dimension of the array Z . $lda \geq \max(1, n)$.

rhs REAL for `slatdf/clatdf`
 DOUBLE PRECISION for `dlatdf/zlatdf`.
 Array, DIMENSION (*n*).
 On entry, *rhs* contains contributions from other subsystems.

rdsum REAL for `slatdf/clatdf`
 DOUBLE PRECISION for `dlatdf/zlatdf`.
 On entry, the sum of squares of computed contributions to the Dif-estimate under computation by `?tgsyL`, where the scaling factor *rdscal* has been factored out. If *trans* = 'T', *rdsum* is not touched.

	Note that <i>rdsum</i> only makes sense when <code>?tgssy2</code> is called by <code>?tgssyL</code>.
<i>rdscal</i>	REAL for <code>slatdf/clatdf</code> DOUBLE PRECISION for <code>dlatdf/zlatdf</code>. On entry, scaling factor used to prevent overflow in <i>rdsum</i>. If <i>trans</i> = <i>T'</i>, <i>rdscal</i> is not touched. Note that <i>rdscal</i> only makes sense when <code>?tgssy2</code> is called by <code>?tgssyL</code>.
<i>ipiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). The pivot indices; for $1 \leq i \leq n$, row <i>i</i> of the matrix has been interchanged with row <i>ipiv</i>(<i>i</i>).
<i>jpiv</i>	INTEGER. Array, DIMENSION (<i>n</i>). The pivot indices; for $1 \leq j \leq n$, column <i>j</i> of the matrix has been interchanged with column <i>jpiv</i>(<i>j</i>).

Output Parameters

<i>rhs</i>	On exit, <i>rhs</i> contains the solution of the subsystem with entries according to the value of <i>ijob</i>.
<i>rdsum</i>	On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If <i>trans</i> = <i>T'</i>, <i>rdsum</i> is not touched.
<i>rdscal</i>	On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i>. If <i>trans</i> = <i>T'</i>, <i>rdscal</i> is not touched.

?latps

Solves a triangular system of equations with the matrix held in packed storage.

Syntax

```
call slatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call dlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call clatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
call zlatps( uplo, trans, diag, normin, n, ap, x, scale, cnorm, info )
```

Description

The routine ?latps solves one of the triangular systems

$A^*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow, where A is an upper or lower triangular matrix stored in packed form. Here A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem does not cause overflow, the Level 2 BLAS routine ?tpsv is called. If the matrix A is singular ($A(j, j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': upper triangular = 'L': uower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^H*x = s*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular. = 'N': non-unit triangular = 'U': unit triangular

<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> is set. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>. $n \geq 0$.
<i>ap</i>	REAL for slatps DOUBLE PRECISION for dlatps COMPLEX for clatps COMPLEX*16 for zlatps. Array, DIMENSION $(n(n+1)/2)$. The upper or lower triangular matrix <i>A</i>, packed columnwise in a linear array. The <i>j</i>-th column of <i>A</i> is stored in the array <i>ap</i> as follows: if <i>uplo</i> = 'U', $ap(i + (j-1)j/2) = A(i, j)$ for $1 \leq i \leq j$; if <i>uplo</i> = 'L', $ap(i + (j-1)(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.
<i>x</i>	REAL for slatps DOUBLE PRECISION for dlatps COMPLEX for clatps COMPLEX*16 for zlatps. Array, DIMENSION (n) On entry, the right hand side <i>b</i> of the triangular system.
<i>cnorm</i>	REAL for slatps/clatps DOUBLE PRECISION for dlatps/zlatps. Array, DIMENSION (n). If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i>(<i>j</i>) contains the norm of the off-diagonal part of the <i>j</i>-th column of <i>A</i>. If <i>trans</i> = 'N', <i>cnorm</i>(<i>j</i>) must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i>(<i>j</i>) must be greater than or equal to the 1-norm.

Output Parameters

<i>x</i>	On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .

scale REAL for slatps/clatps
 DOUBLE PRECISION for dlatps/zlatps.
 The scaling factor s for the triangular system as described above.
 If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $A*x = 0$.

cnorm If $normin = 'N'$, *cnorm* is an output argument and *cnorm*(j) returns the 1-norm of the off-diagonal part of the j -th column of A .

info INTEGER.
 = 0: successful exit
 < 0: if $info = -k$, the k -th argument had an illegal value

?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call slatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call dlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call clatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
call zlatrd( uplo, n, nb, a, lda, e, tau, w, ldw )
```

Description

The routine ?latrd reduces nb rows and columns of a real symmetric or complex Hermitian matrix A to symmetric/Hermitian tridiagonal form by an orthogonal/unitary similarity transformation $Q^T A Q$ for real flavors, $Q^H A Q$ for complex flavors, and returns the matrices v and w which are needed to apply the transformation to the unreduced part of A .

If $uplo = 'U'$, ?latrd reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if `uplo = 'L'`, `?latrd` reduces the first `nb` rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by `?sytrd/?hetrd`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix <i>A</i> is stored: = 'U': upper triangular = 'L': lower triangular
<code>n</code>	INTEGER. The order of the matrix <i>A</i>.
<code>nb</code>	INTEGER. The number of rows and columns to be reduced.
<code>a</code>	REAL for <code>slatrd</code> DOUBLE PRECISION for <code>dlatrd</code> COMPLEX for <code>clatrd</code> COMPLEX*16 for <code>zlatrd</code>. Array, DIMENSION (<i>lda</i>, <i>n</i>). On entry, the symmetric/Hermitian matrix <i>A</i> If <code>uplo = 'U'</code>, the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>a</i> is not referenced. If <code>uplo = 'L'</code>, the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>a</i> is not referenced.
<code>lda</code>	INTEGER. The leading dimension of the array <i>a</i>. <i>lda</i> ≥ (1, <i>n</i>).
<code>ldw</code>	INTEGER. The leading dimension of the output array <i>w</i>. <i>ldw</i> ≥ max(1, <i>n</i>).

Output Parameters

<code>a</code>	On exit, if <code>uplo = 'U'</code>, the last <code>nb</code> columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of <i>a</i>; the elements above

the diagonal with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors;
 if *uplo* = 'L', the first *nb* columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of *a*; the elements below the diagonal with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors.

e REAL for slatrd/clatrd
 DOUBLE PRECISION for dlatrd/zlatrd.
 If *uplo* = 'U', *e*(*n-nb*:*n-1*) contains the superdiagonal elements of the last *nb* columns of the reduced matrix;
 if *uplo* = 'L', *e*(1:*nb*) contains the subdiagonal elements of the first *nb* columns of the reduced matrix.

tau REAL for slatrd
 DOUBLE PRECISION for dlatrd
 COMPLEX for clatrd
 COMPLEX*16 for zlatrd.
 Array, DIMENSION (*lda*, *n*).
 The scalar factors of the elementary reflectors, stored in *tau*(*n-nb*:*n-1*) if *uplo* = 'U', and in *tau*(1:*nb*) if *uplo* = 'L'.

w REAL for slatrd
 DOUBLE PRECISION for dlatrd
 COMPLEX for clatrd
 COMPLEX*16 for zlatrd.
 Array, DIMENSION (*lda*, *n*).
 The *n*-by-*nb* matrix *w* required to update the unreduced part of *A*.

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau u v^*$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $a(1:i-1, i)$, and τ in $\tau(i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form $H(i) = I - \tau v v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+1:n)$ is stored on exit in $a(i+1:n, i)$, and τ in $\tau(i)$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with W , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank-2k update of the form:

$$A := A - VW' - WV'.$$

The contents of a on exit are illustrated by the following examples with $n = 5$ and $nb = 2$:

if $uplo = 'U'$:

$$\begin{bmatrix} a & a & a & v_1 & v_1 \\ & a & a & v_1 & v_1 \\ & & a & 1 & v_1 \\ & & & d & 1 \\ & & & & d \end{bmatrix}$$

if $uplo = 'L'$:

$$\begin{bmatrix} d & & & & \\ & 1 & d & & \\ v_1 & 1 & a & & \\ v_1 & v_1 & a & a & \\ v_1 & v_1 & a & a & a \end{bmatrix}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```
call slatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call dlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call clatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
call zlatrs( uplo, trans, diag, normin, n, a, lda, x, scale, cnorm, info )
```

Description

The routine solves one of the triangular systems

$A^*x = s*b$, or $A^T*x = s*b$, or $A^H*x = s*b$ (for complex flavors)

with scaling to prevent overflow. Here A is an upper or lower triangular matrix, A^T denotes the transpose of A , A^H denotes the conjugate transpose of A , x and b are n -element vectors, and s is a scaling factor, usually less than or equal to 1, chosen so that the components of x will be less than the overflow threshold. If the unscaled problem will not cause overflow, the Level 2 BLAS routine `?trsv` is called. If the matrix A is singular ($A(j,j) = 0$ for some j), then s is set to 0 and a non-trivial solution to $A*x = 0$ is returned.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to A . = 'N': solve $A*x = s*b$ (no transpose) = 'T': solve $A^T*x = s*b$ (transpose) = 'C': solve $A^H*x = s*b$ (conjugate transpose)
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': non-unit triangular = 'U': non-unit triangular

<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. 0 n exit, the norms will be computed and stored in <i>cnorm</i>.
<i>n</i>	INTEGER. The order of the matrix <i>A</i>. $n \geq 0$
<i>a</i>	REAL for slatrs DOUBLE PRECISION for dlatrs COMPLEX for clatrs COMPLEX*16 for zlatrs. Array, DIMENSION (<i>lda</i>, <i>n</i>). Contains the triangular matrix <i>A</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>A</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>A</i> is not referenced. If <i>diag</i> = 'U', the diagonal elements of <i>A</i> are also not referenced and are assumed to be 1.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i>. $lda \geq \max(1, n)$.
<i>x</i>	REAL for slatrs DOUBLE PRECISION for dlatrs COMPLEX for clatrs COMPLEX*16 for zlatrs. Array, DIMENSION (<i>n</i>). On entry, the right hand side <i>b</i> of the triangular system.
<i>cnorm</i>	REAL for slatrs/clatrs DOUBLE PRECISION for dlatrs/zlatrs. Array, DIMENSION (<i>n</i>). If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> (<i>j</i>) contains the norm of the off-diagonal part of the <i>j</i>-th column of <i>A</i>.

If $trans = 'N'$, $cnorm(j)$ must be greater than or equal to the infinity-norm, and if $trans = 'T'$ or $'C'$, $cnorm(j)$ must be greater than or equal to the 1-norm.

Output Parameters

x	On exit, x is overwritten by the solution vector x .
$scale$	REAL for slatrs/clatrs DOUBLE PRECISION for dlatrs/zlatrs. Array, DIMENSION (lda, n). The scaling factor s for the triangular system as described above. If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $A*x = 0$.
$cnorm$	If $normin = 'N'$, $cnorm$ is an output argument and $cnorm(j)$ returns the 1-norm of the off-diagonal part of the j -th column of A .
$info$	INTEGER. = 0: successful exit < 0: if $info = -k$, the k -th argument had an illegal value

Application Notes

A rough bound on x is computed; if that is less than overflow, `?trsv` is called, otherwise, specific code is used which checks for possible overflow or divide-by-zero at every operation.

A columnwise scheme is used for solving $Ax = b$. The basic algorithm if A is lower triangular is

```
x[1:n] := b[1:n]
for j = 1, ..., n
  x(j) := x(j) / A(j,j)
  x[j+1:n] := x[j+1:n] - x(j)*a[j+1:n,j]
end
```

Define bounds on the components of x after j iterations of the loop:

```
M(j) = bound on x[1:j]
G(j) = bound on x[j+1:n]
```

Initially, let $M(0) = 0$ and $G(0) = \max\{x(i), i=1, \dots, n\}$.

Then for iteration $j+1$ we have

$$M(j+1) \leq G(j) / |a(j+1, j+1)|$$

$$G(j+1) \leq G(j) + M(j+1) * |a[j+2:n, j+1]|$$

$$\leq G(j) (1 + cnorm(j+1) / |a(j+1, j+1)|),$$

where $cnorm(j+1)$ is greater than or equal to the infinity-norm of column $j+1$ of a , not counting the diagonal. Hence

$$G(j) \leq G(0) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

and

$$|x(j)| \leq (G(0)/|A(j,j)|) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i,i)|)$$

Since $|x(j)| \leq M(j)$, we use the Level 2 BLAS routine `?trsv` if the reciprocal of the largest $M(j)$, $j=1, \dots, n$, is larger than $\max(\text{underflow}, 1/\text{overflow})$.

The bound on $x(j)$ is also used to determine when a step in the columnwise method can be performed without fear of overflow. If the computed bound is greater than a large constant, x is scaled to prevent overflow, but if the bound overflows, x is set to 0, $x(j)$ to 1, and scale to 0, and a non-trivial solution to $Ax = 0$ is found.

Similarly, a row-wise scheme is used to solve $A^T x = b$ or $A^H x = b$. The basic algorithm for A upper triangular is

for $j = 1, \dots, n$

$x(j) := (b(j) - A[1:j-1, j]' * x[1:j-1]) / A(j, j)$

end

We simultaneously compute two bounds

$$G(j) = \text{bound on } (b(i) - A[1:i-1, i]' * x[1:i-1]), \quad 1 \leq i \leq j$$

$M(j)$ = bound on $x(i)$, $1 \leq i \leq j$

The initial values are $G(0) = 0$, $M(0) = \max\{b(i), i=1, \dots, n\}$, and we add the constraint $G(j) \geq G(j-1)$ and $M(j) \geq M(j-1)$ for $j \geq 1$.

Then the bound on $x(j)$ is

$$M(j) \leq M(j-1) * (1 + cnorm(j)) / |A(j, j)|$$

$$\leq M(0) \prod_{1 \leq i \leq j} (1 + cnorm(i)/|A(i, i)|)$$

and we can safely call ?trsv if $1/M(n)$ and $1/G(n)$ are both greater than $\max(\text{underflow}, 1/\text{overflow})$.

?latrz

Factors an upper trapezoidal matrix by means of orthogonal/unitary transformations.

Syntax

```
call slatz( m, n, l, a, lda, tau, work )
call dlatrz( m, n, l, a, lda, tau, work )
call clatz( m, n, l, a, lda, tau, work )
call zlatrz( m, n, l, a, lda, tau, work )
```

Description

The routine ?latrz factors the m -by- $(m+1)$ real/complex upper trapezoidal matrix

$$[A1 \ A2] = [A(1:m, 1:m) \ A(1:m, n-l+1:n)]$$

as $(R \ 0)^* Z$, by means of orthogonal/unitary transformations. Z is an $(m+1)$ -by- $(m+1)$ orthogonal/unitary matrix and R and $A1$ are m -by- m upper triangular matrices.

Input Parameters

m INTEGER. The number of rows of the matrix A . $m \geq 0$.

<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> . $n \geq 0$.
<i>l</i>	INTEGER. The number of columns of the matrix <i>A</i> containing the meaningful part of the Householder vectors. $n-m \geq l \geq 0$.
<i>a</i>	REAL for slatz DOUBLE PRECISION for dlatrz COMPLEX for clatz COMPLEX*16 for zlatrz. Array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, the leading <i>m</i> -by- <i>n</i> upper trapezoidal part of the array <i>a</i> must contain the matrix to be factorized.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.
<i>work</i>	REAL for slatz DOUBLE PRECISION for dlatrz COMPLEX for clatz COMPLEX*16 for zlatrz. Workspace array, DIMENSION (<i>m</i>).

Output Parameters

<i>a</i>	On exit, the leading <i>m</i> -by- <i>m</i> upper triangular part of <i>a</i> contains the upper triangular matrix <i>R</i> , and elements $n-l+1$ to <i>n</i> of the first <i>m</i> rows of <i>a</i> , with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Z</i> as a product of <i>m</i> elementary reflectors.
<i>tau</i>	REAL for slatz DOUBLE PRECISION for dlatrz COMPLEX for clatz COMPLEX*16 for zlatrz. Array, DIMENSION (<i>m</i>). The scalar factors of the elementary reflectors.

Application Notes

The factorization is obtained by Householder's method. The *k*-th transformation matrix, $z(k)$, which is used to introduce zeros into the (*m* - *k* + 1)-th row of *A*, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix}$$

where

$$T(k) = I - \tau u(k) u(k)^T, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an l -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of $A2$.

The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $A2$, such that the elements of $z(k)$ are in $a(k, l+1), \dots, a(k, n)$.

The elements of r are returned in the upper triangular part of $A1$.

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

slauu2

Computes the product $U*U^T(U*U^H)$ or $L^T*L(L^H*L)$, where U and L are upper or lower triangular matrices (unblocked algorithm).

Syntax

```
call slauu2( uplo, n, a, lda, info )
call dlauu2( uplo, n, a, lda, info )
call clauu2( uplo, n, a, lda, info )
call zlauu2( uplo, n, a, lda, info )
```

Description

The routine ?lauu2 computes the product U^*U^T or L^T*L for real flavors, and L^H*L or L^H*L for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in A .

If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in A .

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the triangular factor stored in the array a is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	INTEGER. The order of the triangular factor U or L . $n \geq 0$.
<i>a</i>	REAL for slauu2 DOUBLE PRECISION for dlauu2 COMPLEX for clauu2 COMPLEX*16 for zlauu2. Array, DIMENSION (lda, n). On entry, the triangular factor U or L .
<i>lda</i>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, if $uplo = 'U'$, then the upper triangle of a is overwritten with the upper triangle of the product $U^*U^T(U^*U^H)$; if $uplo = 'L'$, then the lower triangle of a is overwritten with the lower triangle of the product $L^T*L(L^H*L)$.
<i>info</i>	INTEGER. = 0: successful exit

< 0: if *info* = -*k*, the *k*-th argument had an illegal value

?lauum

Computes the product $U^*U^T(U^*U^H)$ or $L^T*L(L^H*L)$, where U and L are upper or lower triangular matrices (blocked algorithm).

Syntax

```
call slauum( uplo, n, a, lda, info )
call dlauum( uplo, n, a, lda, info )
call clauum( uplo, n, a, lda, info )
call zlauum( uplo, n, a, lda, info )
```

Description

The routine ?lauum computes the product U^*U^T or L^T*L for real flavors, and L^H*L or L^H*L for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array *a*.

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor U in *A*.

If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor L in *A*.

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the triangular factor stored in the array <i>a</i> is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	INTEGER. The order of the triangular factor U or L . $n \geq 0$.
<i>a</i>	REAL for slauum DOUBLE PRECISION for dlauum COMPLEX for clauum

COMPLEX*16 for `zlauum`.

Array, DIMENSION (`lda`, `n`).

On entry, the triangular factor U or L .

`lda`

INTEGER. The leading dimension of the array `a`. $lda \geq \max(1, n)$.

Output Parameters

`a`

On exit,

if `uplo` = 'U', then the upper triangle of `a` is overwritten with the upper triangle of the product $U^*U^T(U^*U^H)$;

if `uplo` = 'L', then the lower triangle of `a` is overwritten with the lower triangle of the product $L^T*L(L^H*L)$.

`info`

INTEGER.

= 0: successful exit

< 0: if `info` = $-k$, the k -th argument had an illegal value

?lazq3

Checks for deflation, computes a shift and calls `dqds`.

Syntax

```
call slazq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee,
  ttype, dmin1, dmin2, dn, dn1, dn2, tau )
```

```
call dlazq3( i0, n0, z, pp, dmin, sigma, desig, qmax, nfail, iter, ndiv, ieee,
  ttype, dmin1, dmin2, dn, dn1, dn2, tau )
```

Description

The routine `?lazq3` checks for deflation, computes a shift (`tau`) and calls `dqds`. In case of failure, it changes shifts, and tries again until output is positive.

This routine is a thread safe version of `?lasq3` routine, which passes `ttype`, `dmin1`, `dmin2`, `dn`, `dn1`, `dn2`, and `tau` through the argument list in place of declaring them in a `SAVE` statement.

Input Parameters

`i0`

INTEGER.

	First index.
<i>n0</i>	INTEGER.
	Last index.
<i>z</i>	REAL for slasq3 DOUBLE PRECISION for dlasq3. Array, DIMENSION (4*n). <i>z</i> holds the <i>qd</i> array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>desig</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Lower order part of <i>sigma</i> .
<i>qmax</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Maximum value of <i>q</i> .
<i>ieee</i>	LOGICAL. Flag for IEEE or non-IEEE arithmetic (passed to the routine).
<i>ttype</i>	INTEGER. Shift type.
<i>dmin1</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dmin2</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Minimum value of <i>d</i> , excluding <i>d</i> (<i>n0</i>) and <i>d</i> (<i>n0</i> -1) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dn</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Contains <i>d</i> (<i>n</i>) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dn1</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3. Contains <i>d</i> (<i>n</i> -1) . Should be 0 on entry at the first iteration and should not be modified further.
<i>dn2</i>	REAL for slazq3 DOUBLE PRECISION for dlazq3.

Contains $d(n-2)$. Should be 0 on entry at the first iteration and should not be modified further.

tau REAL for slazq3
DOUBLE PRECISION for dlazq3.
Shift value

Output Parameters

dmin REAL for slazq3
DOUBLE PRECISION for dlazq3.
Minimum value of d .

sigma REAL for slazq3
DOUBLE PRECISION for dlazq3.
Sum of shifts used in current segment.

desig Lower order part of *sigma*.

nfail INTEGER.
Number of times shift was too big.

iter INTEGER.
Number of iterations.

ndiv INTEGER.
Number of divisions.

ttype Shift type.

dmin1 Minimum value of d , excluding $d(n0)$.

dmin2 Minimum value of d , excluding $d(n0)$ and $d(n0-1)$.

dn $d(n)$.

dn1 $d(n-1)$.

dn2 $d(n-2)$.

tau Shift value.

?lazq4

Computes an approximation to the smallest eigenvalue using values of d from the previous transform.

Syntax

```
call slazq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau,
           ttype, g )
```

```
call dlazq4( i0, n0, z, pp, n0in, dmin, dmin1, dmin2, dn, dn1, dn2, tau,
           ttype, g )
```

Description

The routine computes an approximation τ to the smallest eigenvalue using values of d from the previous transform.

This routine is a thread safe version of ?lasq4 routine, which passes g through the argument list in place of declaring g in a `SAVE` statement.

Input Parameters

<i>i0</i>	INTEGER. First index.
<i>n0</i>	INTEGER. Last index.
<i>z</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Array, DIMENSION (4*n). <i>z</i> holds the qd array.
<i>pp</i>	INTEGER. <i>pp</i> =0 for ping, <i>pp</i> =1 for pong.
<i>n0in</i>	INTEGER. The value of <i>n0</i> at start of eigtest.
<i>dmin</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Minimum value of d .
<i>dmin1</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4.

<i>dmin2</i>	Minimum value of d, excluding $d(n0)$. REAL for slazq4 DOUBLE PRECISION for dlazq4. Minimum value of d, excluding $d(n0)$ and $d(n0-1)$.
<i>dn</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Contains $d(n)$.
<i>dn1</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Contains $d(n-1)$.
<i>dn2</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Contains $d(n-2)$.
<i>g</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Shift coefficient.

Output Parameters

<i>tau</i>	REAL for slazq4 DOUBLE PRECISION for dlazq4. Shift value.
<i>ttype</i>	INTEGER. Shift type.
<i>g</i>	Shift coefficient.

?org2l/?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by ?geqlf (unblocked algorithm).

Syntax

```
call sorg2l( m, n, k, a, lda, tau, work, info )
call dorg2l( m, n, k, a, lda, tau, work, info )
call cung2l( m, n, k, a, lda, tau, work, info )
call zung2l( m, n, k, a, lda, tau, work, info )
```

Description

The routine ?org2l/?ung2l generates an m -by- n real/complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$Q = H(k) * \dots * H(2) * H(1)$ as returned by ?geqlf.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $m \geq n \geq 0$.
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for sorg2l DOUBLE PRECISION for dorg2l COMPLEX for cung2l COMPLEX*16 for zung2l. Array, DIMENSION (lda,n). On entry, the $(n-k+i)$ -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqlf in the last k columns of its array argument A.

lda INTEGER. The first dimension of the array *a*. $lda \geq \max(1, m)$.

tau REAL for sorg2l
DOUBLE PRECISION for dorg2l
COMPLEX for cung2l
COMPLEX*16 for zung2l.
Array, DIMENSION (*k*).
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqlf.

work REAL for sorg2l
DOUBLE PRECISION for dorg2l
COMPLEX for cung2l
COMPLEX*16 for zung2l.
Workspace array, DIMENSION (*n*).

Output Parameters

a On exit, the m -by- n matrix Q .

info INTEGER.
= 0: successful exit
< 0: if *info* = -*i*, the *i*-th argument has an illegal value

?org2r/?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by ?geqrf (unblocked algorithm).

Syntax

```
call sorg2r( m, n, k, a, lda, tau, work, info )
call dorg2r( m, n, k, a, lda, tau, work, info )
call cung2r( m, n, k, a, lda, tau, work, info )
call zung2r( m, n, k, a, lda, tau, work, info )
```

Description

The routine `?org2r/?ung2r` generates an m -by- n real/complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `?geqrf`.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $m \geq n \geq 0$.
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for <code>sorg2r</code> DOUBLE PRECISION for <code>dorg2r</code> COMPLEX for <code>cung2r</code> COMPLEX*16 for <code>zung2r</code> . Array, DIMENSION (lda, n). On entry, the i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>?geqrf</code> in the first k columns of its array argument a .
lda	INTEGER. The first DIMENSION of the array a . $lda \geq \max(1, m)$.
τ	REAL for <code>sorg2r</code> DOUBLE PRECISION for <code>dorg2r</code> COMPLEX for <code>cung2r</code> COMPLEX*16 for <code>zung2r</code> . Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>?geqrf</code> .
$work$	REAL for <code>sorg2r</code> DOUBLE PRECISION for <code>dorg2r</code>

COMPLEX for `cung2r`
 COMPLEX*16 for `zung2r`.
 Workspace array, DIMENSION (n).

Output Parameters

`a` On exit, the m -by- n matrix Q .
`info` INTEGER.
 = 0: successful exit
 < 0: if `info` = $-i$, the i -th argument has an illegal value

?orgl2/?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by ?gelqf (unblocked algorithm).

Syntax

```
call sorgl2( m, n, k, a, lda, tau, work, info )
call dorgl2( m, n, k, a, lda, tau, work, info )
call cungl2( m, n, k, a, lda, tau, work, info )
call zungl2( m, n, k, a, lda, tau, work, info )
```

Description

The routine ?orgl2/?ungl2 generates a m -by- n real/complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = H(k) * \dots * H(2) * H(1)$ for real flavors, or $Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ for complex flavors as returned by ?gelqf.

Input Parameters

`m` INTEGER. The number of rows of the matrix Q . $m \geq 0$.
`n` INTEGER. The number of columns of the matrix Q . $n \geq m$.
`k` INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.

<i>a</i>	REAL for sorgl2 DOUBLE PRECISION for dorgl2 COMPLEX for cungl2 COMPLEX*16 for zungl2. Array, DIMENSION (<i>lda</i>, <i>n</i>). On entry, the <i>i</i>-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gelqf in the first <i>k</i> rows of its array argument <i>a</i>.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i>. $lda \geq \max(1, m)$.
<i>tau</i>	REAL for sorgl2 DOUBLE PRECISION for dorgl2 COMPLEX for cungl2 COMPLEX*16 for zungl2. Array, DIMENSION (<i>k</i>). <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?gelqf.
<i>work</i>	REAL for sorgl2 DOUBLE PRECISION for dorgl2 COMPLEX for cungl2 COMPLEX*16 for zungl2. Workspace array, DIMENSION (<i>m</i>).

Output Parameters

<i>a</i>	On exit, the <i>m</i> -by- <i>n</i> matrix Q .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument has an illegal value.

?orgr2/?ungr2

Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by ?gerqf (unblocked algorithm).

Syntax

```
call sorgr2( m, n, k, a, lda, tau, work, info )
call dorgr2( m, n, k, a, lda, tau, work, info )
call cungr2( m, n, k, a, lda, tau, work, info )
call zungr2( m, n, k, a, lda, tau, work, info )
```

Description

The routine ?orgr2/?ungr2 generates an m -by- n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or $Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ for complex flavors as returned by ?gerqf.

Input Parameters

m	INTEGER. The number of rows of the matrix Q . $m \geq 0$.
n	INTEGER. The number of columns of the matrix Q . $n \geq m$
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for sorgr2 DOUBLE PRECISION for dorgr2 COMPLEX for cungr2 COMPLEX*16 for zungr2. Array, DIMENSION (lda, n). On entry, the ($m-k+1$)-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gerqf in the last k rows of its array argument a .

lda INTEGER. The first dimension of the array *a*. $lda \geq \max(1, m)$.

tau REAL for `sorghr2`
 DOUBLE PRECISION for `dorghr2`
 COMPLEX for `cungr2`
 COMPLEX*16 for `zungr2`.
 Array, `DIMENSION (k).tau(i)` must contain the scalar factor of the elementary reflector $H(i)$, as returned by `?gerqf`.

work REAL for `sorghr2`
 DOUBLE PRECISION for `dorghr2`
 COMPLEX for `cungr2`
 COMPLEX*16 for `zungr2`.
 Workspace array, `DIMENSION (m)`.

Output Parameters

a On exit, the m -by- n matrix Q .

info INTEGER.
 = 0: successful exit
 < 0: if *info* = $-i$, the i -th argument has an illegal value

?orm2l/?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by ?geqlf (unblocked algorithm).

Syntax

```
call sorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2l( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

The routine `?orm2l/?unm2l` overwrites the general real/complex m -by- n matrix C with Q^*C if *side* = 'L' and *trans* = 'N', or

$Q^T * C / Q^H * C$ if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

$C * Q$ if *side* = 'R' and *trans* = 'N', or

$C * Q^T / C * Q^H$ if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by `?geqlf`.

Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If <i>side</i> = 'L', $m \geq k \geq 0$; if <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	REAL for <code>sorm21</code> DOUBLE PRECISION for <code>dorm21</code> COMPLEX for <code>cunm21</code> COMPLEX*16 for <code>zunm21</code> . Array, DIMENSION (<i>lda</i> , <i>k</i>). The i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>?geqlf</code> in the last k columns of its array argument <i>a</i> . The array <i>a</i> is modified by the routine but restored on exit.

<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i>. If <i>side</i> = 'L', $lda \geq \max(1, m)$ if <i>side</i> = 'R', $lda \geq \max(1, n)$.
<i>tau</i>	REAL for sorm2l DOUBLE PRECISION for dorm2l COMPLEX for cunm2l COMPLEX*16 for zunm2l. Array, DIMENSION (<i>k</i>). <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqlf.
<i>c</i>	REAL for sorm2l DOUBLE PRECISION for dorm2l COMPLEX for cunm2l COMPLEX*16 for zunm2l. Array, DIMENSION (<i>ldc</i>, <i>n</i>). On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i>. $ldc \geq \max(1, m)$.
<i>work</i>	REAL for sorm2l DOUBLE PRECISION for dorm2l COMPLEX for cunm2l COMPLEX*16 for zunm2l. Workspace array, DIMENSION: (<i>n</i>) if <i>side</i> = 'L', (<i>m</i>) if <i>side</i> = 'R'.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by Q^*C or Q^T*C / Q^H*C, or $C*Q$, or $C*Q^T / C*Q^H$.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value

?orm2r/?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by ?geqrf (unblocked algorithm).

Syntax

```
call sorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunm2r( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

The routine ?orm2r/?unm2r overwrites the general real/complex m -by- n matrix C with

Q^*C if $side = 'L'$ and $trans = 'N'$, or

$Q^T C / Q^H C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$C Q$ if $side = 'R'$ and $trans = 'N'$, or

$C Q^T / C Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ as returned by ?geqrf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)

<i>m</i>	INTEGER. The number of rows of the matrix <i>C</i> . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>C</i> . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . If <i>side</i> = 'L', $m \geq k \geq 0$; if <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	REAL for sorm2r DOUBLE PRECISION for dorm2r COMPLEX for cunm2r COMPLEX*16 for zunm2r. Array, DIMENSION (<i>lda</i> , <i>k</i>). The <i>i</i> -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?geqrf in the first <i>k</i> columns of its array argument <i>a</i> . The array <i>a</i> is modified by the routine but restored on exit.
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . If <i>side</i> = 'L', $lda \geq \max(1, m)$; if <i>side</i> = 'R', $lda \geq \max(1, n)$.
<i>tau</i>	REAL for sorm2r DOUBLE PRECISION for dorm2r COMPLEX for cunm2r COMPLEX*16 for zunm2r. Array, DIMENSION (<i>k</i>). <i>tau</i> (<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?geqrf.
<i>c</i>	REAL for sorm2r DOUBLE PRECISION for dorm2r COMPLEX for cunm2r COMPLEX*16 for zunm2r. Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the <i>m</i> -by- <i>n</i> matrix <i>C</i> .
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $ldc \geq \max(1, m)$.
<i>work</i>	REAL for sorm2r

DOUBLE PRECISION for dorm2r
 COMPLEX for cunm2r
 COMPLEX*16 for zunm2r.
 Workspace array, DIMENSION
 (n) if *side* = 'L',
 (m) if *side* = 'R'.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by Q^*C or Q^T*C / Q^H*C , or $C*Q$, or $C*Q^T / C*Q^H$.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = -i, the i-th argument had an illegal value

?orml2/?unml2

Multiplies a general matrix by the orthogonal/unitary matrix from a LQ factorization determined by ?gelqf (unblocked algorithm).

Syntax

```
call sorml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dorml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunml2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

The routine ?orml2/?unml2 overwrites the general real/complex *m*-by-*n* matrix *C* with

Q^*C if *side* = 'L' and *trans* = 'N', or

Q^T*C / Q^H*C if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

$C*Q$ if *side* = 'R' and *trans* = 'N', or

$C*Q^T / C*Q^H$ if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ for real flavors, or $Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ for complex flavors as returned by ?gelqf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	REAL for sorml2 DOUBLE PRECISION for dorml2 COMPLEX for cunml2 COMPLEX*16 for zunml2. Array, DIMENSION (<i>lda</i> , <i>m</i>) if $side = 'L'$, (<i>lda</i> , <i>n</i>) if $side = 'R'$ The i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gelqf in the first k rows of its array argument a . The array a is modified by the routine but restored on exit.
<i>lda</i>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, k)$.

<i>tau</i>	REAL for sorml2 DOUBLE PRECISION for dorml2 COMPLEX for cunml2 COMPLEX*16 for zunml2. Array, DIMENSION (<i>k</i>). <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?gelqf.
<i>c</i>	REAL for sorml2 DOUBLE PRECISION for dorml2 COMPLEX for cunml2 COMPLEX*16 for zunml2. Array, DIMENSION (<i>ldc</i>, <i>n</i>) On entry, the <i>m</i>-by-<i>n</i> matrix <i>C</i>.
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i>. $ldc \geq \max(1, m)$.
<i>work</i>	REAL for sorml2 DOUBLE PRECISION for dorml2 COMPLEX for cunml2 COMPLEX*16 for zunml2. Workspace array, DIMENSION (<i>n</i>) if <i>side</i> = 'L', (<i>m</i>) if <i>side</i> = 'R'

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by Q^*C or $Q^T * C / Q^H * C$, or C^*Q, or C^*Q^T / C^*Q^H.
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value

?ormr2/?unmr2

Multiplies a general matrix by the orthogonal/unitary matrix from a RQ factorization determined by ?gerqf (unblocked algorithm).

Syntax

```
call sormr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call dormr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call cunmr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
call zunmr2( side, trans, m, n, k, a, lda, tau, c, ldc, work, info )
```

Description

The routine ?ormr2/?unmr2 overwrites the general real/complex m -by- n matrix C with

Q^*C if $side = 'L'$ and $trans = 'N'$, or

$Q^T * C / Q^H * C$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$C * Q$ if $side = 'R'$ and $trans = 'N'$, or

$C * Q^T / C * Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ for real flavors, or $Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ as returned by ?gerqf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors)

= 'C': apply Q^H (conjugate transpose, for complex flavors)

m INTEGER. The number of rows of the matrix *C*. $m \geq 0$.

n INTEGER. The number of columns of the matrix *C*. $n \geq 0$.

k INTEGER. The number of elementary reflectors whose product defines the matrix *Q*.
 If *side* = 'L', $m \geq k \geq 0$;
 if *side* = 'R', $n \geq k \geq 0$.

a REAL for sormr2
 DOUBLE PRECISION for dormr2
 COMPLEX for cunmr2
 COMPLEX*16 for zunmr2.
 Array, DIMENSION
 (*lda*, *m*) if *side* = 'L',
 (*lda*, *n*) if *side* = 'R'
 The *i*-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?gerqf in the last *k* rows of its array argument *a*. The array *a* is modified by the routine but restored on exit.

lda INTEGER.
 The leading dimension of the array *a*. $lda \geq \max(1, k)$.

tau REAL for sormr2
 DOUBLE PRECISION for dormr2
 COMPLEX for cunmr2
 COMPLEX*16 for zunmr2.
 Array, DIMENSION (*k*).
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?gerqf.

c REAL for sormr2
 DOUBLE PRECISION for dormr2
 COMPLEX for cunmr2
 COMPLEX*16 for zunmr2.
 Array, DIMENSION (*ldc*, *n*).
 On entry, the *m*-by-*n* matrix *C*.

ldc INTEGER. The leading dimension of the array *c*. $ldc \geq \max(1, m)$.

work REAL for sormr2
 DOUBLE PRECISION for dormr2
 COMPLEX for cunmr2
 COMPLEX*16 for zunmr2.
 Workspace array, DIMENSION
 (*n*) if *side* = 'L',
 (*m*) if *side* = 'R'

Output Parameters

c On exit, *c* is overwritten by Q^*C or $Q^T * C$ / $Q^H * C$, or $C * Q$, or $C * Q^T$ / $C * Q^H$.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value

?ormr3/?unmr3

Multiplies a general matrix by the orthogonal/unitary matrix from a RZ factorization determined by ?tzzrf (unblocked algorithm).

Syntax

```
call sormr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call dormr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call cunmr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
call zunmr3( side, trans, m, n, k, l, a, lda, tau, c, ldc, work, info )
```

Description

The routine ?ormr3/?unmr3 overwrites the general real/complex *m*-by-*n* matrix *C* with

Q^*C if *side* = 'L' and *trans* = 'N', or

$Q^T * C$ / $Q^H * C$ if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

$C*Q$ if $side = 'R'$ and $trans = 'N'$, or

$C*Q^T / C*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

Here Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(1)*H(2)*\dots*H(k)$ as returned by ?tzrzf.

Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	CHARACTER*1. = 'L': apply Q or Q^T / Q^H from the left = 'R': apply Q or Q^T / Q^H from the right
<i>trans</i>	CHARACTER*1. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	INTEGER. The number of rows of the matrix C . $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix C . $n \geq 0$.
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>l</i>	INTEGER. The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If $side = 'L'$, $m \geq l \geq 0$, if $side = 'R'$, $n \geq l \geq 0$.
<i>a</i>	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Array, DIMENSION (lda, m) if $side = 'L'$, (lda, n) if $side = 'R'$

The i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by ?tzzrzf in the last k rows of its array argument a . The array a is modified by the routine but restored on exit.

<i>lda</i>	INTEGER. The leading dimension of the array a . $lda \geq \max(1, k)$.
<i>tau</i>	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Array, DIMENSION (k). $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by ?tzzrzf.
<i>c</i>	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Array, DIMENSION (ldc, n). On entry, the m -by- n matrix C .
<i>ldc</i>	INTEGER. The leading dimension of the array c . $ldc \geq \max(1, m)$.
<i>work</i>	REAL for sormr3 DOUBLE PRECISION for dormr3 COMPLEX for cunmr3 COMPLEX*16 for zunmr3. Workspace array, DIMENSION (n) if $side = 'L'$, (m) if $side = 'R'$.

Output Parameters

<i>c</i>	On exit, c is overwritten by Q^*C or Q^T*C / Q^H*C , or $C*Q$, or $C*Q^T / C*Q^H$.
<i>info</i>	INTEGER. = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value

?pbtf2

Computes the Cholesky factorization of a symmetric/ Hermitian positive-definite band matrix (unblocked algorithm).

Syntax

```
call spbtf2( uplo, n, kd, ab, ldab, info )
call dpbtf2( uplo, n, kd, ab, ldab, info )
call cpbtf2( uplo, n, kd, ab, ldab, info )
call zpbtf2( uplo, n, kd, ab, ldab, info )
```

Description

The routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite band matrix A .

The factorization has the form

$A = U^T * U$ for real flavors, $A = U^H * U$ for complex flavors if $uplo = 'U'$, or

$A = L * L^T$ for real flavors, $A = L * L^H$ for complex flavors if $uplo = 'L'$,

where U is an upper triangular matrix, and L is lower triangular. This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored: = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals of the matrix A if $uplo = 'U'$, or the number of sub-diagonals if $uplo = 'L'$. $kd \geq 0$.
<i>ab</i>	REAL for spbtf2

DOUBLE PRECISION for dpbtf2

COMPLEX for cpbtf2

COMPLEX*16 for zpbtf2.

Array, DIMENSION (*ldab*, *n*).

On entry, the upper or lower triangle of the symmetric/Hermitian band matrix *A*, stored in the first *kd*+1 rows of the array. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows:

if *uplo* = 'U', $ab(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$;

if *uplo* = 'L', $ab(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

ldab

INTEGER. The leading dimension of the array *ab*. *ldab* $\geq kd+1$.

Output Parameters

ab

On exit, If *info* = 0, the triangular factor *U* or *L* from the Cholesky factorization $A=U^T*U$ ($A=U^H*U$), or $A=L*L^T$ ($A=L*L^H$) of the band matrix *A*, in the same storage format as *A*.

info

INTEGER.

= 0: successful exit

< 0: if *info* = -*k*, the *k*-th argument had an illegal value

> 0: if *info* = *k*, the leading minor of order *k* is not positive definite, and the factorization could not be completed.

?potf2

Computes the Cholesky factorization of a symmetric/Hermitian positive-definite matrix (unblocked algorithm).

Syntax

```
call spotf2( uplo, n, a, lda, info )
call dpotf2( uplo, n, a, lda, info )
call cpotf2( uplo, n, a, lda, info )
call zpotf2( uplo, n, a, lda, info )
```

Description

The routine ?potf2 computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite matrix A . The factorization has the form

$A = U^T * U$ for real flavors, $A = U^H * U$ for complex flavors if $uplo = 'U'$, or

$A = L * L^T$ for real flavors, $A = L * L^H$ for complex flavors if $uplo = 'L'$,

where U is an upper triangular matrix, and L is lower triangular.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#)

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored. = 'U': upper triangular = 'L': lower triangular
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$.
<i>a</i>	REAL for spotf2 DOUBLE PRECISION or dpotf2 COMPLEX for cpotf2 COMPLEX*16 for zpotf2. Array, DIMENSION (lda, n). On entry, the symmetric/Hermitian matrix A .

If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER. The leading dimension of the array a .

$lda \geq \max(1, n)$.

Output Parameters

a On exit, If $info = 0$, the factor U or L from the Cholesky factorization $A = U^T * U$ ($A = U^H * U$), or $A = L * L^T$ ($A = L * L^H$).

$info$ INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument had an illegal value

> 0: if $info = k$, the leading minor of order k is not positive definite, and the factorization could not be completed.

?ptts2

Solves a tridiagonal system of the form $A * X = B$ using the $L * D * L^H / L * D * L^H$ factorization computed by ?pttrf.

Syntax

```
call sptts2( n, nrhs, d, e, b, ldb )
call dptts2( n, nrhs, d, e, b, ldb )
call cptts2( iuplo, n, nrhs, d, e, b, ldb )
call zptts2( iuplo, n, nrhs, d, e, b, ldb )
```

Description

The routine ?ptts2 solves a tridiagonal system of the form

$$A * X = B$$

Real flavors `sptts2/dptts2` use the $L^*D^*L^T$ factorization of A computed by `spttrf/dpttrf`, and complex flavors `cptts2/zptts2` use the U^H*D*U or $L^*D^*L^H$ factorization of A computed by `cpttrf/zpttrf`.

D is a diagonal matrix specified in the vector d , U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector e , and X and B are n -by- $nrhs$ matrices.

Input Parameters

<i>iuplo</i>	INTEGER. Used with complex flavors only. Specifies the form of the factorization, and whether the vector e is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 1: $A = U^H*D*U$, e is the superdiagonal of U; = 0: $A = L^*D^*L^H$, e is the subdiagonal of L
<i>n</i>	INTEGER. The order of the tridiagonal matrix A. $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides, that is, the number of columns of the matrix B. $nrhs \geq 0$.
<i>d</i>	REAL for <code>sptts2/cptts2</code> DOUBLE PRECISION for <code>dptts2/zptts2</code>. Array, DIMENSION (n). The n diagonal elements of the diagonal matrix D from the factorization of A.
<i>e</i>	REAL for <code>sptts2</code> DOUBLE PRECISION for <code>dptts2</code> COMPLEX for <code>cptts2</code> COMPLEX*16 for <code>zptts2</code>. Array, DIMENSION ($n-1$). Contains the ($n-1$) subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^T$ (for real flavors) or $L^*D^*L^H$ (for complex flavors when $iuplo = 0$) factorization of A. For complex flavors when $iuplo = 1$, e contains the ($n-1$) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U^H*D*U$.
<i>B</i>	REAL for <code>sptts2/cptts2</code> DOUBLE PRECISION for <code>dptts2/zptts2</code>.

Array, DIMENSION (ldb , $nrhs$).

On entry, the right hand side vectors B for the system of linear equations.

ldb

INTEGER. The leading dimension of the array B . $ldb \geq \max(1, n)$.

Output Parameters

b

On exit, the solution vectors, x .

?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
call srscl( n, sa, sx, incx )
```

```
call drscl( n, sa, sx, incx )
```

```
call csrscl( n, sa, sx, incx )
```

```
call zdrscl( n, sa, sx, incx )
```

Description

The routine ?rscl multiplies an n -element real/complex vector x by the real scalar $1/a$. This is done without overflow or underflow as long as the final result x/a does not overflow or underflow.

Input Parameters

n

INTEGER. The number of components of the vector x .

sa

REAL for srscl/csrscl

DOUBLE PRECISION for drscl/zdrscl.

The scalar a which is used to divide each component of the vector x . sa must be ≥ 0 , or the subroutine will divide by zero.

sx

REAL for srscl

DOUBLE PRECISION for drscl

COMPLEX for csrscl

COMPLEX*16 for `zdrsl`.
 Array, DIMENSION $(1+(n-1) * |incx|)$.
 The n -element vector x .
`incx` INTEGER. The increment between successive values of the vector sx .
 If $incx > 0$, $sx(1)=x(1)$, and $sx(1+(i-1)*incx)=x(i)$, $1 < i \leq n$.

Output Parameters

`sx` On exit, the result x/a .

?sygs2/?hegs2

Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from ?potrf (unblocked algorithm).

Syntax

```
call ssygs2( itype, uplo, n, a, lda, b, ldb, info )
call dsygs2( itype, uplo, n, a, lda, b, ldb, info )
call chgs2( itype, uplo, n, a, lda, b, ldb, info )
call zhegs2( itype, uplo, n, a, lda, b, ldb, info )
```

Description

The routine ?sygs2/?hegs2 reduces a real symmetric-definite or a complex Hermitian-definite generalized eigenproblem to standard form.

If $itype = 1$, the problem is

$$A*x = \lambda*B*x$$

and A is overwritten by $inv(U')*A*inv(U)$, or $inv(L)*A*inv(L')$.

If $itype = 2$ or 3 , the problem is

$$A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x,$$

and A is overwritten by U^*A^*U' or L'^*A^*L . Here $U'(L')$ is the transpose (conjugate transpose) of $U(L)$.

B must be previously factorized as U'^*U or L^*L' by ?potrf.

Input Parameters

itype INTEGER.
 = 1: compute $\text{inv}(U')^*A^*\text{inv}(U)$, or $\text{inv}(L)^*A^*\text{inv}(L')$;
 = 2 or 3: compute U^*A^*U' , or L'^*A^*L .

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored, and how B has been factorized.
 = 'U': upper triangular
 = 'L': lower triangular

n INTEGER. The order of the matrices A and B . $n \geq 0$.

a REAL for ssygs2
 DOUBLE PRECISION for dsygs2
 COMPLEX for chegs2
 COMPLEX*16 for zhegs2.
 Array, DIMENSION (lda, n).
 On entry, the symmetric/Hermitian matrix A .
 If *uplo* = 'U', the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.
 If *uplo* = 'L', the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER.
 The leading dimension of the array a . $lda \geq \max(1, n)$.

b REAL for ssygs2
 DOUBLE PRECISION for dsygs2
 COMPLEX for chegs2
 COMPLEX*16 for zhegs2.
 Array, DIMENSION (ldb, n).
 The triangular factor from the Cholesky factorization of B as returned by ?potrf.

ldb INTEGER. The leading dimension of the array *b*. $ldb \geq \max(1, n)$.

Output Parameters

a On exit, If *info* = 0, the transformed matrix, stored in the same format as *A*.

info INTEGER.
 = 0: successful exit.
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value.

?sytd2/?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation(unblocked algorithm).

Syntax

```
call ssytd2( uplo, n, a, lda, d, e, tau, info )
call dsytd2( uplo, n, a, lda, d, e, tau, info )
call chetd2( uplo, n, a, lda, d, e, tau, info )
call zhetd2( uplo, n, a, lda, d, e, tau, info )
```

Description

The routine ?sytd2/?hetd2 reduces a real symmetric/complex Hermitian matrix *A* to real symmetric tridiagonal form *T* by an orthogonal/unitary similarity transformation: $Q^T A Q = T$ ($Q^H A Q = T$).

Input Parameters

uplo CHARACTER*1.
 Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix *A* is stored:
 = 'U': upper triangular
 = 'L': lower triangular

n INTEGER. The order of the matrix *A*. $n \geq 0$.

a REAL for ssytd2
 DOUBLE PRECISION for dsytd2
 COMPLEX for chetd2
 COMPLEX*16 for zhetd2.
 Array, DIMENSION (*lda*, *n*).
 On entry, the symmetric/Hermitian matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *a* contains the upper triangular part of the matrix *A*, and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *a* contains the lower triangular part of the matrix *A*, and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, if *uplo* = 'U', the diagonal and first superdiagonal of *a* are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors;
 if *uplo* = 'L', the diagonal and first subdiagonal of *a* are overwritten by the corresponding elements of the tridiagonal matrix *T*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors.

d REAL for ssytd2/chetd2
 DOUBLE PRECISION for dsytd2/zhetd2.
 Array, DIMENSION (*n*).
 The diagonal elements of the tridiagonal matrix *T*:
 $d(i) = a(i, i)$.

e REAL for ssytd2/chetd2
 DOUBLE PRECISION for dsytd2/zhetd2.
 Array, DIMENSION (*n*-1).
 The off-diagonal elements of the tridiagonal matrix *T*:
 $e(i) = a(i, i+1)$ if *uplo* = 'U',

	$e(i) = a(i+1,i)$ if <code>uplo = 'L'</code> .
<code>tau</code>	REAL for ssytd2 DOUBLE PRECISION for dsytd2 COMPLEX for chetd2 COMPLEX*16 for zhetd2. Array, DIMENSION (<i>n</i>). The first <i>n</i>-1 elements contain scalar factors of the elementary reflectors. <code>tau(n)</code> is used as workspace.
<code>info</code>	INTEGER. = 0: successful exit < 0: if <code>info = -i</code>, the <i>i</i>-th argument had an illegal value.

?sytf2

Computes the factorization of a real/complex symmetric indefinite matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call ssytf2( uplo, n, a, lda, ipiv, info )
call dsytf2( uplo, n, a, lda, ipiv, info )
call csytf2( uplo, n, a, lda, ipiv, info )
call zsytf2( uplo, n, a, lda, ipiv, info )
```

Description

The routine `?sytf2` computes the factorization of a real/complex symmetric matrix *A* using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U^T (A = U^* D^* U^H), \text{ or } A = L^* D^* L^T (A = L^* D^* L^H),$$

where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, and *D* is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<code>uplo</code>	CHARACTER*1.

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored
 = 'U': upper triangular
 = 'L': lower triangular

n INTEGER. The order of the matrix A . $n \geq 0$.

a REAL for ssytf2
 DOUBLE PRECISION for dsytf2
 COMPLEX for csytf2
 COMPLEX*16 for zsytf2.
 Array, DIMENSION (lda, n).
 On entry, the symmetric matrix A .
 If *uplo* = 'U', the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced.
 If *uplo* = 'L', the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

lda INTEGER.
 The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

a On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .

ipiv INTEGER.
 Array, DIMENSION (n).
 Details of the interchanges and the block structure of D
 If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ are interchanged and $D(k,k)$ is a 1-by-1 diagonal block.
 If *uplo* = 'U' and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ are interchanged and $D(k,k)$ is a 2-by-2 diagonal block.
 If *uplo* = 'L' and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info INTEGER.
 = 0: successful exit

< 0: if *info* = -*k*, the *k*-th argument has an illegal value
 > 0: if *info* = *k*, *D*(*k*,*k*) is exactly zero. The factorization are completed, but the block diagonal matrix *D* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

zhetf2

Computes the factorization of a complex Hermitian matrix, using the diagonal pivoting method (unblocked algorithm).

Syntax

```
call chetf2( uplo, n, a, lda, ipiv, info )
call zhetf2( uplo, n, a, lda, ipiv, info )
```

Description

The routine computes the factorization of a complex Hermitian matrix *A* using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D^* U' \text{ or } A = L^* D^* L'$$

where *U* (or *L*) is a product of permutation and unit upper (lower) triangular matrices, *U'* is the conjugate transpose of *U*, and *D* is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling [BLAS Level 2 Routines](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	INTEGER. The order of the matrix <i>A</i> . $n \geq 0$.
<i>A</i>	COMPLEX for chetf2 COMPLEX*16 for zhetf2. Array, DIMENSION (<i>lda</i> , <i>n</i>).

On entry, the Hermitian matrix A .

If $uplo = 'U'$, the leading n -by- n upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

lda

INTEGER. The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

a

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L .

ipiv

INTEGER. Array, DIMENSION (n).

Details of the interchanges and the block structure of D

If $ipiv(k) > 0$, then rows and columns k and $ipiv(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block.

If $uplo = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, then rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block.

If $uplo = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, then rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

info

INTEGER.

= 0: successful exit

< 0: if $info = -k$, the k -th argument had an illegal value

> 0: if $info = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

?tgex2

Swaps adjacent diagonal blocks in an upper (quasi) triangular matrix pair by an orthogonal/unitary equivalence transformation.

Syntax

```
call stgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2,
work, lwork, info )

call dtgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, n1, n2,
work, lwork, info )

call ctgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
call ztgex2( wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, j1, info )
```

Description

The real routines `stgex2/dtgex2` swap adjacent diagonal blocks (A_{11} , B_{11}) and (A_{22} , B_{22}) of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair (A , B) by an orthogonal equivalence transformation. (A , B) must be in generalized real Schur canonical form (as returned by `sgges/dgges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex routines `ctgex2/ztgex2` swap adjacent diagonal 1-by-1 blocks (A_{11} , B_{11}) and (A_{22} , B_{22}) in an upper triangular matrix pair (A , B) by an unitary equivalence transformation.

(A , B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

All routines optionally update the matrices Q and Z of generalized Schur vectors:

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'$, where Z' is the transpose (conjugate transpose) of Z .

Input Parameters

<code>wantq</code>	LOGICAL. If <code>wantq = .TRUE.</code> : update the left transformation matrix Q ; If <code>wantq = .FALSE.</code> : do not update Q .
<code>wantz</code>	LOGICAL.

If *wantz* = .TRUE. : update the right transformation matrix *Z*;
 If *wantz* = .FALSE. : do not update *Z*.

n INTEGER. The order of the matrices *A* and *B*. $n \geq 0$.

a, b REAL for stgex2 DOUBLE PRECISION for dtgex2
 COMPLEX for ctgex2
 COMPLEX*16 for ztgex2.
Arrays, DIMENSION (*lda*, *n*) and (*ldb*, *n*), respectively.
On entry, the matrices *A* and *B* in the pair (*A*, *B*).

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

ldb INTEGER. The leading dimension of the array *b*. $ldb \geq \max(1, n)$.

q, z REAL for stgex2 DOUBLE PRECISION for dtgex2
 COMPLEX for ctgex2
 COMPLEX*16 for ztgex2.
Arrays, DIMENSION (*ldq*, *n*) and (*ldz*, *n*), respectively.
On entry, if *wantq* = .TRUE., *q* contains the
orthogonal/unitary matrix *Q*, and if *wantz* = .TRUE., *z*
contains the orthogonal/unitary matrix *Z*.

ldq INTEGER. The leading dimension of the array *q*. $ldq \geq 1$.
 If *wantq* = .TRUE., $ldq \geq n$.

ldz INTEGER. The leading dimension of the array *z*. $ldz \geq 1$.
 If *wantz* = .TRUE., $ldz \geq n$.

j1 INTEGER.
The index to the first block (*A11*, *B11*). $1 \leq j1 \leq n$.

n1 INTEGER. Used with real flavors only. The order of the first
block (*A11*, *B11*). $n1 = 0, 1$ or 2 .

n2 INTEGER. Used with real flavors only. The order of the
second block (*A22*, *B22*). $n2 = 0, 1$ or 2 .

work REAL for stgex2
 DOUBLE PRECISION for dtgex2.

Workspace array, `DIMENSION (max(1, lwork))`. Used with real flavors only.

lwork

INTEGER. The dimension of the array *work*.

$lwork \geq \max(n * (n2 + n1), 2 * (n2 + n1)^2)$

Output Parameters

a

On exit, the updated matrix *A*.

B

On exit, the updated matrix *B*.

Q

On exit, the updated matrix *Q*.

Not referenced if *wantq* = .FALSE..

z

On exit, the updated matrix *Z*.

Not referenced if *wantz* = .FALSE..

info

INTEGER.

=0: Successful exit For *stgex2/dtgex2*: If *info* = 1, the transformed matrix (*A*, *B*) would be too far from generalized Schur form; the blocks are not swapped and (*A*, *B*) and (*Q*, *Z*) are unchanged. The problem of swapping is too ill-conditioned. If *info* = -16: *lwork* is too small.

Appropriate value for *lwork* is returned in *work*(1).

For *ctgex2/ztgex2*:

If *info* = 1, the transformed matrix pair (*A*, *B*) would be too far from generalized Schur form; the problem is ill-conditioned.

?tgsy2

Solves the generalized Sylvester equation (unblocked algorithm).

Syntax

```
call stgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
            ldf, scale, rdsum, rdscal, iwork, pq, info )

call dtgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
            ldf, scale, rdsum, rdscal, iwork, pq, info )

call ctgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
            ldf, scale, rdsum, rdscal, iwork, pq, info )

call ztgsy2( trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f,
            ldf, scale, rdsum, rdscal, iwork, pq, info )
```

Description

The routine ?tgsy2 solves the generalized Sylvester equation:

$$A^*R - L^*B = \text{scale}^*C \quad (1)$$

$$D^*R - L^*E = \text{scale}^*F$$

using Level 1 and 2 BLAS, where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively. For stgsy2/dtgsy2, pairs (A, D) and (B, E) must be in generalized Schur canonical form, that is, A, B are upper quasi triangular and D, E are upper triangular. For ctgsy2/ztgsy2, matrices A, B, D and E are upper triangular (that is, (A, D) and (B, E) in generalized Schur form).

The solution (R, L) overwrites (C, F) .

$0 \leq \text{scale} \leq 1$ is an output scaling factor chosen to avoid overflow.

In matrix notation, solving equation (1) corresponds to solve

$$Z^*x = \text{scale}^*b$$

where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_n) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_n) \end{bmatrix} \quad (2)$$

Here I_k is the identity matrix of size k and x' is the transpose (conjugate transpose) of x .
 $\text{kron}(X, Y)$ denotes the Kronecker product between the matrices X and Y .

If $trans = 'T'$, solve the transposed (conjugate transposed) system

$$Z' * y = scale * b$$

for y , which is equivalent to solve for R and L in

$$A' * R + D' * L = scale * C \quad (3)$$

$$R * B' + L * E' = scale * (-F)$$

This case is used to compute an estimate of $\text{Dif}[(A, D), (B, E)] = \text{sigma\_min}(Z)$ using reverse communication with [?lacon](#).

[?tgssy2](#) also (for $ijob \geq 1$) contributes to the computation in [?tgssyl](#) of an upper bound on the separation between two matrix pairs. Then the input (A, D) , (B, E) are sub-pencils of the matrix pair (two matrix pairs) in [?tgssyl](#). See [?tgssyl](#) for details.

Input Parameters

<i>trans</i>	CHARACTER*1. If $trans = 'N'$, solve the generalized Sylvester equation (1); If $trans = 'T'$: solve the 'transposed' system (3).
<i>ijob</i>	INTEGER. Specifies what kind of functionality is to be performed. If $ijob = 0$: solve (1) only. If $ijob = 1$: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (look ahead strategy is used); If $ijob = 2$: a contribution from this subsystem to a Frobenius norm-based estimate of the separation between two matrix pairs is computed (?gecon on sub-systems is used). Not referenced if $trans = 'T'$.

<i>m</i>	INTEGER. On entry, <i>m</i> specifies the order of <i>A</i> and <i>D</i> , and the row dimension of <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> .
<i>n</i>	INTEGER. On entry, <i>n</i> specifies the order of <i>B</i> and <i>E</i> , and the column dimension of <i>C</i> , <i>F</i> , <i>R</i> and <i>L</i> .
<i>a</i> , <i>b</i>	REAL for stgsy2 DOUBLE PRECISION for dtgsy2 COMPLEX for ctgsy2 COMPLEX*16 for ztgsy2. Arrays, DIMENSION (<i>lda</i> , <i>m</i>) and (<i>ldb</i> , <i>n</i>), respectively. On entry, <i>a</i> contains an upper (quasi) triangular matrix <i>A</i> , and <i>b</i> contains an upper (quasi) triangular matrix <i>B</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> . $lda \geq \max(1, m)$.
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$.
<i>c</i> , <i>f</i>	REAL for stgsy2 DOUBLE PRECISION for dtgsy2 COMPLEX for ctgsy2 COMPLEX*16 for ztgsy2. Arrays, DIMENSION (<i>ldc</i> , <i>n</i>) and (<i>ldf</i> , <i>n</i>), respectively. On entry, <i>c</i> contains the right-hand-side of the first matrix equation in (1), and <i>f</i> contains the right-hand-side of the second matrix equation in (1).
<i>ldc</i>	INTEGER. The leading dimension of the array <i>c</i> . $ldc \geq \max(1, m)$.
<i>d</i> , <i>e</i>	REAL for stgsy2 DOUBLE PRECISION for dtgsy2 COMPLEX for ctgsy2 COMPLEX*16 for ztgsy2. Arrays, DIMENSION (<i>ldd</i> , <i>m</i>) and (<i>lde</i> , <i>n</i>), respectively. On entry, <i>d</i> contains an upper triangular matrix <i>D</i> , and <i>e</i> contains an upper triangular matrix <i>E</i> .
<i>ldd</i>	INTEGER. The leading dimension of the array <i>d</i> . $ldd \geq \max(1, m)$.

<i>lde</i>	INTEGER. The leading dimension of the array <i>e</i> . $lde \geq \max(1, n)$.
<i>ldf</i>	INTEGER. The leading dimension of the array <i>f</i> . $ldf \geq \max(1, m)$.
<i>rdsum</i>	REAL for stgsy2/ctgsy2 DOUBLE PRECISION for dtgsy2/ztgsy2. On entry, the sum of squares of computed contributions to the Dif-estimate under computation by ?tgsyL, where the scaling factor <i>rdscal</i> has been factored out.
<i>rdscal</i>	REAL for stgsy2/ctgsy2 DOUBLE PRECISION for dtgsy2/ztgsy2. On entry, scaling factor used to prevent overflow in <i>rdsum</i> .
<i>iwork</i>	INTEGER. Used with real flavors only. Workspace array, DIMENSION ($m+n+2$).

Output Parameters

<i>c</i>	On exit, if <i>ijob</i> = 0, <i>c</i> is overwritten by the solution <i>R</i> .
<i>f</i>	On exit, if <i>ijob</i> = 0, <i>f</i> is overwritten by the solution <i>L</i> .
<i>scale</i>	REAL for stgsy2/ctgsy2 DOUBLE PRECISION for dtgsy2/ztgsy2. On exit, $0 \leq scale \leq 1$. If $0 < scale < 1$, the solutions <i>R</i> and <i>L</i> (<i>C</i> and <i>F</i> on entry) hold the solutions to a slightly perturbed system, but the input matrices <i>A</i> , <i>B</i> , <i>D</i> and <i>E</i> are not changed. If <i>scale</i> = 0, <i>R</i> and <i>L</i> hold the solutions to the homogeneous system with <i>C</i> = <i>F</i> = 0. Normally <i>scale</i> = 1.
<i>rdsum</i>	On exit, the corresponding sum of squares updated with the contributions from the current sub-system. If <i>trans</i> = 'T', <i>rdsum</i> is not touched. Note that <i>rdsum</i> only makes sense when ?tgsy2 is called by ?tgsyl.
<i>rdscal</i>	On exit, <i>rdscal</i> is updated with respect to the current contributions in <i>rdsum</i> . If <i>trans</i> = 'T', <i>rdscal</i> is not touched.

	Note that <i>rdscal</i> only makes sense when <i>?tgsyl</i> is called by <i>?tgsyl</i> .
<i>pq</i>	INTEGER. Used with real flavors only. On exit, the number of subsystems (of size 2-by-2, 4-by-4 and 8-by-8) solved by the routine <i>stgsy2/dtgsy2</i> .
<i>info</i>	INTEGER. On exit, if <i>info</i> is set to = 0: Successful exit < 0: If <i>info</i> = <i>-i</i> , the <i>i</i> -th argument has an illegal value. > 0: The matrix pairs (<i>A</i> , <i>D</i>) and (<i>B</i> , <i>E</i>) have common or very close eigenvalues.

?trti2

Computes the inverse of a triangular matrix (unblocked algorithm).

Syntax

```
call strti2( uplo, diag, n, a, lda, info )
call dtrti2( uplo, diag, n, a, lda, info )
call ctrti2( uplo, diag, n, a, lda, info )
call ztrti2( uplo, diag, n, a, lda, info )
```

Description

The routine *?trti2* computes the inverse of a real/complex upper or lower triangular matrix. This is the *Level 2 BLAS* version of the algorithm.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular. = 'U': upper triangular = 'L': lower triangular
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix <i>A</i> is unit triangular. = 'N': non-unit triangular = 'U': unit triangular

n INTEGER. The order of the matrix *A*. $n \geq 0$.

a REAL for `strti2`
 DOUBLE PRECISION for `dtrti2`
 COMPLEX for `ctrti2`
 COMPLEX*16 for `ztrti2`.
 Array, DIMENSION (*lda*, *n*).
 On entry, the triangular matrix *A*.
 If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of the array *a* contains the upper triangular matrix, and the strictly lower triangular part of *a* is not referenced.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of the array *a* contains the lower triangular matrix, and the strictly upper triangular part of *a* is not referenced.
 If *diag* = 'U', the diagonal elements of *a* are also not referenced and are assumed to be 1.

lda INTEGER. The leading dimension of the array *a*. $lda \geq \max(1, n)$.

Output Parameters

a On exit, the (triangular) inverse of the original matrix, in the same storage format.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = *-k*, the *k*-th argument had an illegal value

clag2z

Converts a complex single precision matrix to a complex double precision matrix.

Syntax

```
call clag2z( m, n, sa, ldsa, a, lda, info )
```

Description

The routine converts a complex single precision matrix *SA* to a complex double precision matrix *A*.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsa \geq \max(1, m)$.
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

dlag2s

Converts a double precision matrix to a single precision matrix.

Syntax

```
call dlag2s( m, n, a, lda, sa, ldsa, info )
```

Description

The routine converts a double precision matrix *SA* to a single precision matrix *A*.

RMAX is the overflow for the single precision arithmetic. `dlag2s` checks that all the entries of *A* are between -RMAX and RMAX. If not, the conversion is aborted and a flag is raised.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsa \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>k</i> , the (<i>i</i> , <i>j</i>) entry of the matrix <i>A</i> has overflowed when moving from double precision to single precision. <i>k</i> is given by $k = (i-1)*lda+j$.

slag2d

Converts a single precision matrix to a double precision matrix.

Syntax

```
call slag2d( m, n, sa, ldsa, a, lda, info )
```

Description

The routine converts a single precision matrix *SA* to a double precision matrix *A*.

Note that while it is possible to overflow while converting from double to single, it is not possible to overflow when converting from single to double.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsa \geq \max(1, m)$.
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

zlag2c

Converts a complex double precision matrix to a complex single precision matrix.

Syntax

```
call zlag2c( m, n, a, lda, sa, ldsa, info )
```

Description

The routine converts a double precision complex matrix *SA* to a single precision complex matrix *A*.

RMAX is the overflow for the single precision arithmetic. *zlag2c* checks that all the entries of *A* are between $-RMAX$ and *RMAX*. If not, the conversion is aborted and a flag is raised.

This is a helper routine so there is no argument checking.

Input Parameters

<i>m</i>	INTEGER. The number of lines of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	DOUBLE PRECISION array, DIMENSION (<i>lda</i> , <i>n</i>). On entry, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>A</i> .
<i>lda</i>	INTEGER. The leading dimension of the array <i>a</i> ; $lda \geq \max(1, m)$.
<i>ldsa</i>	INTEGER. The leading dimension of the array <i>sa</i> ; $ldsa \geq \max(1, m)$.

Output Parameters

<i>sa</i>	REAL array, DIMENSION (<i>ldsa</i> , <i>n</i>). On exit, if <i>info</i> = 0, contains the <i>m</i> -by- <i>n</i> coefficient matrix <i>SA</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>k</i> , the (<i>i</i> , <i>j</i>) entry of the matrix <i>A</i> has overflowed when moving from double precision to single precision. <i>k</i> is given by $k = (i-1)*lda+j$.

Utility Functions and Routines

This section describes LAPACK utility functions and routines. Summary information about these routines is given in the following table:

Table 5-2 LAPACK Utility Routines

Routine Name	Data Types	Description
<i>ilaver</i>		Returns the version of the Lapack library.
<i>ilaenv</i>		Environmental enquiry function which returns values for tuning algorithmic performance.
<i>iparmq</i>		Environmental enquiry function which returns values for tuning algorithmic performance.

Routine Name	Data Types	Description
ieeeck		Checks if the infinity and NaN arithmetic is safe. Called by ilaenv .
lsame		Tests two characters for equality regardless of case.
lsamen		Tests two character strings for equality regardless of case.
?labad	s, d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
?lamch	s, d	Determines machine parameters for floating-point arithmetic.
?lamc1	s, d	Called from ?lamc2 . Determines machine parameters given by <i>beta</i> , <i>t</i> , <i>rnd</i> , <i>ieee1</i> .
?lamc2	s, d	Used by ?lamch . Determines machine parameters specified in its arguments list.
?lamc3	s, d	Called from ?lamc1 - ?lamc5 . Intended to force <i>a</i> and <i>b</i> to be stored prior to doing the addition of <i>a</i> and <i>b</i> .
?lamc4	s, d	This is a service routine for ?lamc2 .
?lamc5	s, d	Called from ?lamc2 . Attempts to compute the largest machine floating-point number, without overflow.
second/dsecnd		Return user time for a process.
xerbla		Error handling routine called by LAPACK routines.

ilaver

Returns the version of the Lapack library.

Syntax

```
call ilaver( vers_major, vers_minor, vers_patch )
```

Description

This routine returns the version of the Lapack library.

Output Parameters

<code>vers_major</code>	INTEGER. Returns the major version of the LAPACK library.
<code>vers_minor</code>	INTEGER. Returns the minor version from the major version of the LAPACK library.
<code>vers_patch</code>	INTEGER. Returns the patch version from the minor version of the LAPACK library.

ilaenv

Environmental enquiry function that returns values for tuning algorithmic performance.

Syntax

```
value = ilaenv( ispec, name, opts, n1, n2, n3, n4 )
```

Description

Enquiry function `ilaenv` is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See *ispec* below for a description of the parameters.

This version provides a set of parameters that should give good, but not optimal, performance on many of the currently available computers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

Input Parameters

<code>ispec</code>	INTEGER. Specifies the parameter to be returned as the value of <code>ilaenv</code> : = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance.

= 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used.
 = 3: the crossover point (in a block routine, for n less than this value, an unblocked routine should be used)
 = 4: the number of shifts, used in the nonsymmetric eigenvalue routines (deprecated)
 = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k -by- m , where k is given by `ilaenv(2,...)` and m by `ilaenv(5,...)`
 = 6: the crossover point for the SVD (when reducing an m -by- n matrix to bidiagonal form, if $\max(m,n)/\min(m,n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.)
 = 7: the number of processors
 = 8: the crossover point for the multishift QR and QZ methods for nonsymmetric eigenvalue problems (deprecated).
 = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by `?gelss` and `?gesdd`)
 =10: ieee NaN arithmetic can be trusted not to trap
 =11: infinity arithmetic can be trusted not to trap
 $12 \leq ispec \leq 16$: `?hseqr` or one of its subroutines, see `iparmq` for detailed explanation.

name CHARACTER*(*). The name of the calling subroutine, in either upper case or lower case.

opts CHARACTER*(*). The character options to the subroutine *name*, concatenated into a single character string. For example, *uplo* = 'U', *trans* = 'T', and *diag* = 'N' for a triangular routine would be specified as *opts* = 'UTN'.

n1, n2, n3, n4 INTEGER. Problem dimensions for the subroutine *name*; these may not all be required.

Output Parameters

value INTEGER.

If *value* ≥ 0 : the value of the parameter specified by *ispec*;
 If *value* = $-k < 0$: the *k*-th argument had an illegal value.

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.
2. The problem dimensions *n1*, *n2*, *n3*, *n4* are specified in the order that they appear in the argument list for *name*. *n1* is used first, *n2* second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by `ilaenv` is checked for validity in the calling subroutine. For example, `ilaenv` is used to retrieve the optimal blocksize for `strtri` as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1> )
if( nb.le.1 ) nb = max( 1, n )
```

Below is an example of `ilaenv` usage in C language:

```
#include <stdio.h>
#include "mkl.h"
int main(void)
{
    int size = 1000;
    int ispec = 1;
    int dummy = -1;
    int blockSize1 = ilaenv(&ispec, "dsytrd", "U", &size, &dummy, &dummy, &dummy);
    int blockSize2 = ilaenv(&ispec, "dormtr", "LUN", &size, &size, &dummy, &dummy);
    printf("DSYTRD blocksize = %d\n", blockSize1);
    printf("DORMTR blocksize = %d\n", blockSize2);
    return 0;
}
```

iparmq

Environmental enquiry function which returns values for tuning algorithmic performance.

Syntax

```
value = iparmq( ispec, name, opts, n, ilo, ihi, lwork )
```

Description

This function sets problem and machine dependent parameters useful for ?hseqr and its subroutines. It is called whenever ilaenv is called with $12 \leq ispec \leq 16$.

Input Parameters

ispec INTEGER.
Specifies the parameter to be returned as the value of iparmq:

- = 12: (*inmin*) Matrices of order *nmin* or less are sent directly to ?lahqr, the implicit double shift QR algorithm. *nmin* must be at least 11.
- = 13: (*inwin*) Size of the deflation window. This is best set greater than or equal to the number of simultaneous shifts *ns*. Larger matrices benefit from larger deflation windows.
- = 14: (*inibl*) Determines when to stop nibbling and invest in an (expensive) multi-shift QR sweep. If the aggressive early deflation subroutine finds *ld* converged eigenvalues from an order *nw* deflation window and $ld > (nw * nibble) / 100$, then the next QR sweep is skipped and early deflation is applied immediately to the remaining active diagonal block. Setting iparmq(*ispec*=14)=0 causes TTQRE to skip a multi-shift QR sweep whenever early deflation finds a converged eigenvalue. Setting iparmq(*ispec*=14) greater than or equal to 100 prevents TTQRE from skipping a multi-shift QR sweep.
- = 15: (*nshfts*) The number of simultaneous shifts in a multi-shift QR iteration.
- = 16: (*iacc22*) iparmq is set to 0, 1 or 2 with the following meanings.

0: During the multi-shift QR sweep, `?laqr5` does not accumulate reflections and does not use matrix-matrix multiply to update the far-from-diagonal matrix entries.
 1: During the multi-shift QR sweep, `?laqr5` and/or `?laqr3` accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries.
 2: During the multi-shift QR sweep, `?laqr5` accumulates reflections and takes advantage of 2-by-2 block structure during matrix-matrix multiplies.
 (If `?trrm` is slower than `?gemm`, then `iparmq(ispec=16)=1` may be more efficient than `iparmq(ispec=16)=2` despite the greater level of arithmetic work implied by the latter choice.)

<i>name</i>	CHARACTER*(*) . The name of the calling subroutine.
<i>opts</i>	CHARACTER*(*) . This is a concatenation of the string arguments to TTQRE.
<i>n</i>	INTEGER. <i>n</i> is the order of the Hessenberg matrix <i>H</i> .
<i>ilo, ihi</i>	INTEGER. It is assumed that <i>H</i> is already upper triangular in rows and columns 1: <i>ilo</i> -1 and <i>ihi</i> +1: <i>n</i> .
<i>lwork</i>	INTEGER. The amount of workspace available.

Output Parameters

<i>value</i>	INTEGER. If <i>value</i> ≥ 0: the value of the parameter specified by <i>iparmq</i> ; If <i>value</i> = -k < 0: the k-th argument had an illegal value.

Application Notes

The following conventions have been used when calling `ilaenv` from the LAPACK routines:

1. *opts* is a concatenation of all of the character options to subroutine *name*, in the same order that they appear in the argument list for *name*, even if they are not used in determining the value of the parameter specified by *ispec*.

2. The problem dimensions $n1$, $n2$, $n3$, $n4$ are specified in the order that they appear in the argument list for *name*. $n1$ is used first, $n2$ second, and so on, and unused problem dimensions are passed a value of -1.
3. The parameter value returned by *ilaenv* is checked for validity in the calling subroutine. For example, *ilaenv* is used to retrieve the optimal blocksize for *strtri* as follows:

```
nb = ilaenv( 1, 'strtri', uplo // diag, n, -1, -1, -1 )
if( nb.le.1 ) nb = max( 1, n )
```

ieeeck

Checks if the infinity and NaN arithmetic is safe.
Called by *ilaenv*.

Syntax

```
ival = ieeck( ispec, zero, one )
```

Description

The function *ieeeck* is called from *ilaenv* to verify that infinity and possibly NaN arithmetic is safe, that is, will not trap.

Input Parameters

<i>ispec</i>	INTEGER. Specifies whether to test just for infinity arithmetic or both for infinity and NaN arithmetic: If <i>ispec</i> = 0: Verify infinity arithmetic only. If <i>ispec</i> = 1: Verify infinity and NaN arithmetic.
<i>zero</i>	REAL. Must contain the value 0.0 This is passed to prevent the compiler from optimizing away this code.
<i>one</i>	REAL. Must contain the value 1.0 This is passed to prevent the compiler from optimizing away this code.

Output Parameters

<i>ival</i>	INTEGER.

If `ival = 0`: Arithmetic failed to produce the correct answers.
If `ival = 1`: Arithmetic produced the correct answers.

lsame

Tests two characters for equality regardless of case.

Syntax

```
val = lsame(ca, cb)
```

Description

This logical function returns `.TRUE.` if `ca` is the same letter as `cb` regardless of case.

Input Parameters

`ca, cb` CHARACTER*1. Specify the single characters to be compared.

Output Parameters

`val` LOGICAL. Result of the comparison.

lsamen

Tests two character strings for equality regardless of case.

Syntax

```
val = lsamen(n, ca, cb)
```

Description

This logical function tests if the first `n` letters of the string `ca` are the same as the first `n` letters of `cb`, regardless of case. The function `lsamen` returns `.TRUE.` if `ca` and `cb` are equivalent except for case and `.FALSE.` otherwise. `lsamen` also returns `.FALSE.` if `len(ca)` or `len(cb)` is less than `n`.

Input Parameters

<i>n</i>	INTEGER. The number of characters in <i>ca</i> and <i>cb</i> to be compared.
<i>ca, cb</i>	CHARACTER* (*). Specify two character strings of length at least <i>n</i> to be compared. Only the first <i>n</i> characters of each string will be accessed.

Output Parameters

<i>val</i>	LOGICAL. Result of the comparison.

?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call slabad( small, large )
call dlabad( small, large )
```

Description

This routine takes as input the values computed by `slamch/dlamch` for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `?lamch`. This subroutine is needed because `?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

Input Parameters

<i>small</i>	REAL for slabad DOUBLE PRECISION for dlabad. The underflow threshold as computed by <code>?lamch</code> .
<i>large</i>	REAL for slabad DOUBLE PRECISION for dlabad. The overflow threshold as computed by <code>?lamch</code> .

Output Parameters

<i>small</i>	On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
val = slamch( cmach )
```

```
val = dlamch( cmach )
```

Description

The function ?lamch determines single precision and double precision machine parameters.

Input Parameters

<i>cmach</i>	CHARACTER*1. Specifies the value to be returned by ?lamch: = 'E' or 'e', <i>val</i> = <i>eps</i> = 'S' or 's', <i>val</i> = <i>sfmin</i> = 'B' or 'b', <i>val</i> = <i>base</i> = 'P' or 'p', <i>val</i> = <i>eps*base</i> = 'n' or 'n', <i>val</i> = <i>t</i> = 'R' or 'r', <i>val</i> = <i>rnd</i> = 'm' or 'm', <i>val</i> = <i>emin</i> = 'U' or 'u', <i>val</i> = <i>rmin</i> = 'L' or 'l', <i>val</i> = <i>emax</i> = 'O' or 'o', <i>val</i> = <i>rmax</i> where <i>eps</i> = relative machine precision; <i>sfmin</i> = safe minimum, such that $1/\textit{sfmin}$ does not overflow; <i>base</i> = base of the machine; <i>prec</i> = <i>eps*base</i>;

```

t = number of (base) digits in the mantissa;
rnd = 1.0 when rounding occurs in addition, 0.0 otherwise;
emin = minimum exponent before (gradual) underflow;
rmin = underflow_threshold - base**(emin-1);
emax = largest exponent before overflow;
rmax = overflow_threshold - (base**emax)*(1-eps).

```

Output Parameters

<i>val</i>	REAL for slamch DOUBLE PRECISION for dlamch Value returned by the function.

?lamc1

*Called from ?lamc2. Determines machine parameters given by *beta*, *t*, *rnd*, *ieee1*.*

Syntax

```

call slamc1( beta, t, rnd, ieee1 )
call dlamc1( beta, t, rnd, ieee1 )

```

Description

The routine ?lamc1 determines machine parameters given by *beta*, *t*, *rnd*, *ieee1*.

Output Parameters

<i>beta</i>	INTEGER. The base of the machine.
<i>t</i>	INTEGER. The number of (<i>beta</i>) digits in the mantissa.
<i>rnd</i>	LOGICAL. Specifies whether proper rounding (<i>rnd</i> = .TRUE.) or chopping (<i>rnd</i> = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
<i>ieee1</i>	LOGICAL. Specifies whether rounding appears to be done in the <i>ieee</i> 'round to nearest' style.

?lamc2

Used by ?lamch. Determines machine parameters specified in its arguments list.

Syntax

```
call slamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
call dlamc2( beta, t, rnd, eps, emin, rmin, emax, rmax )
```

Description

The routine ?lamc2 determines machine parameters specified in its arguments list.

Output Parameters

<i>beta</i>	INTEGER. The base of the machine.
<i>t</i>	INTEGER. The number of (<i>beta</i>) digits in the mantissa.
<i>rnd</i>	LOGICAL. Specifies whether proper rounding (<i>rnd</i> = .TRUE.) or chopping (<i>rnd</i> = .FALSE.) occurs in addition. This may not be a reliable guide to the way in which the machine performs its arithmetic.
<i>eps</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest positive number such that $fl(1.0 - eps) < 1.0$, where <i>fl</i> denotes the computed value.
<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow occurs.
<i>rmin</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2 The smallest normalized number for the machine, given by $base^{emin-1}$, where <i>base</i> is the floating point value of <i>beta</i> .
<i>emax</i>	INTEGER. The maximum exponent before overflow occurs.
<i>rmax</i>	REAL for slamc2 DOUBLE PRECISION for dlamc2

The largest positive number for the machine, given by $base^{emax(1 - eps)}$, where *base* is the floating point value of *beta*.

?lamc3

*Called from ?lamc1-?lamc5. Intended to force *a* and *b* to be stored prior to doing the addition of *a* and *b*.*

Syntax

```
val = slamc3( a, b )
```

```
val = dlamc3( a, b )
```

Description

The routine is intended to force *A* and *B* to be stored prior to doing the addition of *A* and *B*, for use in situations where optimizers might hold one of these in a register.

Input Parameters

a, b REAL for slamc3
 DOUBLE PRECISION for dlamc3
 The values *a* and *b*.

Output Parameters

val REAL for slamc3
 DOUBLE PRECISION for dlamc3
 The result of adding values *a* and *b*.

?lamc4

This is a service routine for ?lamc2.

Syntax

```
call slamc4( emin, start, base )
```

```
call dlamc4( emin, start, base )
```

Description

This is a service routine for `?lamc2`.

Input Parameters

<i>start</i>	REAL for <code>slamc4</code> DOUBLE PRECISION for <code>dlamc4</code> The starting point for determining <i>emin</i> .
<i>base</i>	INTEGER. The base of the machine.

Output Parameters

<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow, computed by setting <i>a</i> = <i>start</i> and dividing by <i>base</i> until the previous <i>a</i> can not be recovered.

?lamc5

Called from ?lamc2. Attempts to compute the largest machine floating-point number, without overflow.

Syntax

```
call slamc5( beta, p, emin, ieee, emax, rmax)
call dlamc5( beta, p, emin, ieee, emax, rmax)
```

Description

The routine `?lamc5` attempts to compute *rmax*, the largest machine floating-point number, without overflow. It assumes that *emax* + *abs(emin)* sum approximately to a power of 2. It will fail on machines where this assumption does not hold, for example, the Cyber 205 (*emin* = -28625, *emax* = 28718). It will also fail if the value supplied for *emin* is too large (that is, too close to zero), probably with overflow.

Input Parameters

<i>beta</i>	INTEGER. The base of floating-point arithmetic.
<i>p</i>	INTEGER. The number of base <i>beta</i> digits in the mantissa of a floating-point value.

<i>emin</i>	INTEGER. The minimum exponent before (gradual) underflow.
<i>ieee</i>	LOGICAL. A logical flag specifying whether or not the arithmetic system is thought to comply with the IEEE standard.

Output Parameters

<i>emax</i>	INTEGER. The largest exponent before overflow.
<i>rmax</i>	REAL for <code>slamc5</code> DOUBLE PRECISION for <code>dlamc5</code> The largest machine floating-point number.

second/dsecnd

Return user time for a process.

Syntax

```
val = second()
val = dsecnd()
```

Description

The functions `second/dsecnd` return the user time for a process in seconds. These versions get the time from the system function `etime`. The difference is that `dsecnd` returns the result with double precision.

Output Parameters

<i>val</i>	REAL for <code>second</code> DOUBLE PRECISION for <code>dsecnd</code> User time for a process.

xerbla

Error handling routine called by BLAS, LAPACK, VML routines.

Syntax

```
call xerbla( sname, info )
```

Description

The routine `xerbla` is an error handler for the BLAS, LAPACK, and VML routines. It is called by a BLAS, LAPACK, or VML routine if an input parameter has an invalid value.

A message is printed and execution stops.

Installers may consider modifying the `stop` statement to call system-specific exception-handling facilities.

Input Parameters

<i>sname</i>	CHARACTER*6 The name of the routine which called <code>xerbla</code> .
<i>info</i>	INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

ScaLAPACK Routines

6

This chapter describes the Intel® Math Kernel Library implementation of routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks. All routines are available in both single precision and double precision.

NOTE. ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Sections in this chapter include descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on ScaLAPACK routines and related information see [\[SLUG\]](#).

Overview

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. An example of an array descriptor structure is given in [Table 6-1](#).

Table 6-1 Content of the array descriptor for dense matrices

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type (=1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid

Array Element #	Name	Definition
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by $LOC_r()$ and $LOC_c()$, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix A , which is contained in the global subarray $\text{sub}(A)$, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of $\text{sub}(A)$
<i>n</i>	The number of columns of $\text{sub}(A)$
<i>a</i>	A pointer to the local array containing the entire global array A
<i>ia</i>	The row index of $\text{sub}(A)$ in the global array
<i>ja</i>	The column index of $\text{sub}(A)$ in the global array
<i>desca</i>	The array descriptor for the global array

Routine Naming Conventions

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines (see [Routine Naming Conventions in Chapter 4](#)). A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter *p*.

ScaLAPACK names have the structure $p?yyzzz$ or $p?yyzz$, which is described below.

The initial letter *p* is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol *?* indicates the data type:

<i>s</i>	real, single precision
<i>d</i>	real, double precision
<i>c</i>	complex, single precision

z complex, double precision

The second and third letters *yy* indicate the matrix type as:

ge	general
gb	general band
gg	a pair of general matrices (for a generalized problem)
dt	general tridiagonal (diagonally dominant-like)
db	general band (diagonally dominant-like)
po	symmetric or Hermitian positive-definite
pb	symmetric or Hermitian positive-definite band
pt	symmetric or Hermitian positive-definite tridiagonal
sy	symmetric
st	symmetric tridiagonal (real)
he	Hermitian
or	orthogonal
tr	triangular (or quasi-triangular)
tz	trapezoidal
un	unitary

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

sv	a <i>simple</i> driver for solving a linear system
svx	an <i>expert</i> driver for solving a linear system
ls	a driver for solving a linear least squares problem
ev	a simple driver for solving a symmetric eigenvalue problem
evx	an expert driver for solving a symmetric eigenvalue problem
svd	a driver for computing a singular value decomposition
gvx	an expert driver for solving a generalized symmetric definite eigenvalue problem

Simple driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

Linear Equations

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded
- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See [Table 6-2](#) for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding [driver routine](#) that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (*LU* factorization) and then

`p?getrs`(computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

Table 6-2 lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

Table 6-2 Computational Routines for Systems of Linear Equations

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix
general (partial pivoting)	<code>p?getrf</code>	<code>p?geequ</code>	<code>p?getrs</code>	<code>p?gecon</code>	<code>p?gerfs</code>	<code>p?getri</code>
general band (partial pivoting)	<code>p?gbtrf</code>		<code>p?gbtrs</code>			
general band (no pivoting)	<code>p?dbtrf</code>		<code>p?dbtrs</code>			
general tridiagonal (no pivoting)	<code>p?dttrf</code>		<code>p?dttrs</code>			
symmetric/Hermitian positive-definite	<code>p?potrf</code>	<code>p?poequ</code>	<code>p?potrs</code>	<code>p?pocon</code>	<code>p?porfs</code>	<code>p?potri</code>
symmetric/Hermitian positive-definite, band	<code>p?pbtrf</code>		<code>p?pbtrs</code>			
symmetric/Hermitian positive-definite, tridiagonal	<code>p?pttrf</code>		<code>p?pttrs</code>			
triangular			<code>p?trtrs</code>	<code>p?trcon</code>	<code>p?trrfs</code>	<code>p?trtri</code>

In this table ? stands for *s* (single precision real), *d* (double precision real), *c* (single precision complex), or *z* (double precision complex).

Routines for Matrix Factorization

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

p?getrf

Computes the LU factorization of a general m-by-n distributed matrix.

Syntax

```
call psgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pdgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pcgetrf(m, n, a, ia, ja, desca, ipiv, info)
call pzgetrf(m, n, a, ia, ja, desca, ipiv, info)
```

Description

The routine forms the LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ as

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). L and U are stored in $\text{sub}(A)$.

The routine uses partial pivoting, with row interchanges.

Input Parameters

m	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; $m \geq 0$.
n	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; $n \geq 0$.
a	(local) REAL for psgetrf DOUBLE PRECISION for pdgetrf COMPLEX for pcgetrf DOUBLE COMPLEX for pzgetrf. Pointer into the local memory to an array of local dimension $(lld\_a, LOCc(ja+n-1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.

ia, ja (global) INTEGER. The row and column indices in the global array *A* indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

Output Parameters

a Overwritten by local pieces of the factors *L* and *U* from the factorization $A = P * L * U$. The unit diagonal elements of *L* are not stored.

ipiv (local) INTEGER array.
The dimension of *ipiv* is $(LOCr(m\_a) + mb\_a)$.
This array contains the pivoting information: local row *i* was interchanged with global row *ipiv*(*i*). This array is tied to the distributed matrix *A*.

info (global) INTEGER.
If *info*=0, the execution is successful.
info < 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.
If *info* = *i*, u_{ii} is 0. The factorization has been completed, but the factor *U* is exactly singular. Division by zero will occur if you use the factor *U* for solving a system of linear equations.

p?gbtrf

Computes the LU factorization of a general n -by- n banded distributed matrix.

Syntax

```
call psgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pdgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pcgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
call pzgbtrf(n, bwl, bwu, a, ja, desca, ipiv, af, laf, work, lwork, info)
```

Description

The routine computes the LU factorization of a general n -by- n real/complex banded distributed matrix $A(1:n, ja:ja+n-1)$ using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK routine [?gbtrf](#). Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P * L * U * Q$$

where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

n	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
bwl	(global) INTEGER. The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
bwu	(global) INTEGER. The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
a	(local) REAL for psgbtrf

DOUBLE PRECISION for pdgbtrf
 COMPLEX for pcgbtrf
 DOUBLE COMPLEX for pzgbtrf.
 Pointer into the local memory to an array of local dimension
 (lld_a , $LOC_c(ja+n-1)$) where
 $lld\_a \geq 2*bwl + 2*bwu + 1$.
 Contains the local pieces of the n -by- n distributed banded
 matrix $A(1:n, ja:ja+n-1)$ to be factored.

ja (global) INTEGER. The index in the global array *A* that points
 to the start of the matrix to be operated on (which may be
 either all of *A* or a submatrix of *A*).

desca (global and local) INTEGER array, dimension ($dlen\_$). The
 array descriptor for the distributed matrix *A*.
 If $desca(dtype\_)$ = 501, then $dlen\_ \geq 7$;
 else if $desca(dtype\_)$ = 1, then $dlen\_ \geq 9$.

laf (local) INTEGER. The dimension of the array *af*.
 Must be $laf \geq$
 $(NB+bwu) * (bwl+bwu) + 6 * (bwl+bwu) * (bwl+2*bwu)$.
 If *laf* is not large enough, an error code will be returned
 and the minimum acceptable size will be returned in *af*(1).

work (local) Same type as *a*. Workspace array of dimension *lwork*
 .

lwork (local or global) INTEGER. The size of the *work* array ($lwork$
 ≥ 1) . If *lwork* is too small, the minimal acceptable size will
 be returned in *work*(1) and an error code is returned.

Output Parameters

a On exit, this array contains details of the factorization. Note
 that additional permutations are performed on the matrix,
 so that the factors returned are different from those returned
 by LAPACK.

ipiv (local) INTEGER array.
 The dimension of *ipiv* must be $\geq desca(NB)$.

	Contains pivot indices for local factorizations. Note that you <i>should not alter</i> the contents of this array between factorization and solve.
<i>af</i>	(local) REAL for psgbtrf DOUBLE PRECISION for pdgbtrf COMPLEX for pcgbtrf DOUBLE COMPLEX for pzgbtrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?gbtrf and this is stored in <i>af</i>. Note that if a linear system is to be solved using p?gbtrs after the factorization routine, <i>af</i> must not be altered after the factorization.
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>th argument is an array and the <i>j</i>th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>. <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not nonsingular, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i>-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbtrf

Computes the LU factorization of a n -by- n diagonally dominant-like banded distributed matrix.

Syntax

```
call psdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pddbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pcdbrtf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
call pzdbtrf(n, bwl, bwu, a, ja, desca, af, laf, work, lwork, info)
```

Description

The routine computes the LU factorization of a n -by- n real/complex diagonally dominant-like banded distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

Input Parameters

n	(global) INTEGER. The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
bwl	(global) INTEGER. The number of sub-diagonals within the band of A $(0 \leq bwl \leq n-1)$.
bwu	(global) INTEGER. The number of super-diagonals within the band of A $(0 \leq bwu \leq n-1)$.
a	(local) REAL for psdbtrf DOUBLE PRECISION for pddbtrf COMPLEX for pcdbrtf DOUBLE COMPLEX for pzdbtrf. Pointer into the local memory to an array of local dimension $(lld\_a, LOCC(ja+n-1))$.

	Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>a</i> or a submatrix of <i>a</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + (\max(bwl, bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be $lwork \geq (\max(bwl, bwu))^2$. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned.

Output Parameters

<i>a</i>	On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>af</i>	(local) REAL for psdbtrf DOUBLE PRECISION for pddbtrf COMPLEX for pcdbrf DOUBLE COMPLEX for pzdbtrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?dbtrf and this is stored in <i>af</i> .

Note that if a linear system is to be solved using `p?dbtrs` after the factorization routine, `af` must not be altered after the factorization.

`work(1)` On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info` (global) INTEGER.
 If `info=0`, the execution is successful.
`info < 0`:
 If the `i`th argument is an array and the `j`-th entry had an illegal value, then `info = -(i*100+j)`; if the `i`-th argument is a scalar and had an illegal value, then `info = -i`. `info > 0`:
 If `info = k ≤ NPROCS`, the submatrix stored on processor `info` and factored locally was not diagonally dominant-like, and the factorization was not completed. If `info = k > NPROCS`, the submatrix stored on processor `info-NPROCS` representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

```
call pspotrf(uplo, n, a, ia, ja, desca, info)
call pdpotrf(uplo, n, a, ia, ja, desca, info)
call pcpotrf(uplo, n, a, ia, ja, desca, info)
call pzpotrf(uplo, n, a, ia, ja, desca, info)
```

Description

This routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n -by- n matrix $A(ia:ia+n-1, ja:ja+n-1)$, denoted below as $\text{sub}(A)$.

The factorization has the form

$\text{sub}(A) = U^H * U$ if $\text{uplo} = 'U'$, or

$\text{sub}(A) = L * L^H$ if $\text{uplo} = 'L'$

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored. Must be 'U' or 'L'. If $\text{uplo} = 'U'$, the array <i>a</i> stores the upper triangular part of the matrix $\text{sub}(A)$ that is factored as $U^H * U$. If $\text{uplo} = 'L'$, the array <i>a</i> stores the lower triangular part of the matrix $\text{sub}(A)$ that is factored as $L * L^H$.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pspotrf DOUBLE PRECISION for pdpotrf COMPLEX for pcspotrf DOUBLE COMPLEX for pzpotrf. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$ to be factored. Depending on <i>uplo</i> , the array <i>a</i> contains either the upper or the lower triangular part of the matrix $\text{sub}(A)$ (see <i>uplo</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor U or L , as specified by <i>uplo</i> .

info

(global) INTEGER.

If *info*=0, the execution is successful;

info < 0: if the *i*-th argument is an array, and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* = *k* > 0, the leading minor of order *k*, $A(ia:ia+k-1, ja:ja+k-1)$, is not positive-definite, and the factorization could not be completed.

p?pbtrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite banded distributed matrix.

Syntax

```
call pspbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pdpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pcpbtrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
call pzpbtfrf(uplo, n, bw, a, ja, desca, af, laf, work, lwork, info)
```

Description

This routine computes the Cholesky factorization of an *n*-by-*n* real symmetric or complex Hermitian positive-definite banded distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$A(1:n, ja:ja+n-1) = P * U^H * P^T$, if *uplo*='U', or

$A(1:n, ja:ja+n-1) = P * L * L^H * P^T$, if *uplo*='L',

where *P* is a permutation matrix and *U* and *L* are banded upper and lower triangular matrices, respectively.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$. ($n \geq 0$).
<i>bw</i>	(global) INTEGER. The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L'. ($bw \geq 0$).
<i>a</i>	(local) REAL for pspbtrf DOUBLE PRECISION for pdpbtrf COMPLEX for pcgbtrf DOUBLE COMPLEX for pzpbtrf. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the upper or lower triangle of the symmetric/Hermitian band distributed matrix $A(1:n, ja:ja+n-1)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>. If <i>desca</i>(<i>dtype_</i>) = 501, then <i>dlen_</i> $\geq$ 7; else if <i>desca</i>(<i>dtype_</i>) = 1, then <i>dlen_</i> $\geq$ 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i>. Must be <i>laf</i> $\geq$ (NB+2*<i>bw</i>) * <i>bw</i>. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).

work (local) Same type as *a*. Workspace array of dimension *lwork*.

lwork (local or global) INTEGER. The size of the *work* array, must be $lwork \geq bw^2$.

Output Parameters

a On exit, if *info*=0, contains the permuted triangular factor *U* or *L* from the Cholesky factorization of the band matrix $A(1:n, ja:ja+n-1)$, as specified by *uplo*.

af (local)
 REAL for pspbtrf
 DOUBLE PRECISION for pdpbtrf
 COMPLEX for pcpbtrf
 DOUBLE COMPLEX for pzpbtrf.
 Array, dimension (*laf*). Auxiliary Fillin space. Fillin is created during the factorization routine *p?pbtrf* and this is stored in *af*. Note that if a linear system is to be solved using *p?pbtrs* after the factorization routine, *af* must not be altered.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 If *info*=0, the execution is successful.
info < 0:
 If the *i*th argument is an array and the *j*th entry had an illegal value, then $info = -(i*100+j)$; if the *i*th argument is a scalar and had an illegal value, then $info = -i$.
info > 0:
 If $info = k \leq NPROCS$, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
 If $info = k > NPROCS$, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?pttrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite tridiagonal distributed matrix.

Syntax

```
call pspttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pdpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pcpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
call pzpttrf(n, d, e, ja, desca, af, laf, work, lwork, info)
```

Description

This routine computes the Cholesky factorization of an n -by- n real symmetric or complex hermitian positive-definite tridiagonal distributed matrix $A(1:n, ja:ja+n-1)$.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P * L * D * L^H * P^T, \text{ or}$$

$$A(1:n, ja:ja+n-1) = P * U^H * D * U * P^T,$$

where P is a permutation matrix, and U and L are tridiagonal upper and lower triangular matrices, respectively.

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).
d, e	(local) REAL for pspttrf DOUBLE PRECISION for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf. Pointers into the local memory to arrays of dimension $(desca(nb\_))$ each.

	On entry, the array <i>d</i> contains the local part of the global vector storing the main diagonal of the distributed matrix <i>A</i> .
	On entry, the array <i>e</i> contains the local part of the global vector storing the upper diagonal of the distributed matrix <i>A</i> .
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be <i>laf</i> ≥ NB+2. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>d</i> and <i>e</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be at least <i>lwork</i> ≥ 8*NPCOL.

Output Parameters

<i>d, e</i>	On exit, overwritten by the details of the factorization.
<i>af</i>	(local) REAL for pspttrf DOUBLE PRECISION for pdpttrf COMPLEX for pcpttrf DOUBLE COMPLEX for pzpttrf. Array, dimension (<i>laf</i>). Auxiliary Fillin space. Fillin is created during the factorization routine p?pttrf and this is stored in <i>af</i> . Note that if a linear system is to be solved using p?pttrs after the factorization routine, <i>af</i> must not be altered.

<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. If <code>info=0</code>, the execution is successful. <code>info < 0</code>: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry had an illegal value, then <code>info = -(i*100+j)</code>; if the <i>i</i>-th argument is a scalar and had an illegal value, then <code>info = -i</code>. <code>info > 0</code>: If <code>info = k ≤ NPROCS</code>, the submatrix stored on processor <code>info</code> and factored locally was not positive definite, and the factorization was not completed. If <code>info = k > NPROCS</code>, the submatrix stored on processor <code>info-NPROCS</code> representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dttrf

Computes the LU factorization of a diagonally dominant-like tridiagonal distributed matrix.

Syntax

```
call psdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pddttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pcdttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
call pzdtttrf(n, dl, d, du, ja, desca, af, laf, work, lwork, info)
```

Description

This routine computes the LU factorization of an *n*-by-*n* real/complex diagonally dominant-like tridiagonal distributed matrix `A(1:n, ja:ja+n-1)` without pivoting for stability.

The resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form:

$$A(1:n, ja:ja+n-1) = P*L*U*P^T,$$

where P is a permutation matrix, and L and U are banded lower and upper triangular matrices, respectively.

Input Parameters

n (global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).

dl, d, du (local)
 REAL for pspttrf
 DOUBLE PRECISION for pdpttrf
 COMPLEX for pcpttrf
 DOUBLE COMPLEX for pzpttrf.
 Pointers to the local arrays of dimension $(desca(nb\_))$ each.
 On entry, the array *dl* contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, *dl*(1) is not referenced, and *dl* must be aligned with *d*.
 On entry, the array *d* contains the local part of the global vector storing the diagonal elements of the matrix.
 On entry, the array *du* contains the local part of the global vector storing the super-diagonal elements of the matrix. *du*(*n*) is not referenced, and *du* must be aligned with *d*.

ja (global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca (global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix *A*. If $desca(dtype\_)$ = 501, then $dlen\_ \geq 7$;
 else if $desca(dtype\_)$ = 1, then $dlen\_ \geq 9$.

laf (local) INTEGER. The dimension of the array *af*.
 Must be $laf \geq 2*(NB+2)$.
 If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work (local) Same type as *d*. Workspace array of dimension *lwork*.

lwork (local or global) INTEGER. The size of the *work* array, must be at least $lwork \geq 8 * NPCOL$.

Output Parameters

dl, d, du On exit, overwritten by the information containing the factors of the matrix.

af (local)
 REAL for psdtttrf
 DOUBLE PRECISION for pddtttrf
 COMPLEX for pcdtttrf
 DOUBLE COMPLEX for pzdtttrf.
 Array, dimension (*laf*).
 Auxiliary Fillin space. Fillin is created during the factorization routine p?dtttrf and this is stored in *af*.
 Note that if a linear system is to be solved using p?dtttrs after the factorization routine, *af* must not be altered.

work(1) On exit, *work(1)* contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 If *info*=0, the execution is successful.
info < 0:
 If the *i*-th argument is an array and the *j*-th entry had an illegal value, then $info = -(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.
info > 0:
 If $info = k \leq NPCOCS$, the submatrix stored on processor *info* and factored locally was not diagonally dominant-like, and the factorization was not completed. If $info = k > NPCOCS$, the submatrix stored on processor *info*-NPCOCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

Routines for Solving Systems of Linear Equations

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

p?getrs

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by p?getrf.

Syntax

```
call psgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgetrs(trans, n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Description

This routine solves a system of distributed linear equations with a general n -by- n distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the LU factorization computed by p?getrf.

The system has one of the following forms specified by *trans*:

$\text{sub}(A) * X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T * X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H * X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1)$.

Before calling this routine, you must call p?getrf to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If *trans* = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .

	If $trans = 'T'$, then $sub(A)^T * X = sub(B)$ is solved for X. If $trans = 'C'$, then $sub(A)^H * X = sub(B)$ is solved for X.
n	(global) INTEGER. The number of linear equations; the order of the submatrix $sub(A)$ ($n \geq 0$).
$nrhs$	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $sub(B)$ ($nrhs \geq 0$).
a, b	(global) REAL for psgetrs DOUBLE PRECISION for pdgetrs COMPLEX for pcgetrs DOUBLE COMPLEX for pzgetrs. Pointers into the local memory to arrays of local dimension $a(lld\_a, LOCc(ja+n-1))$ and $b(lld\_b, LOCc(jb+nrhs-1))$, respectively. On entry, the array a contains the local pieces of the factors L and U from the factorization $sub(A) = P * L * U$; the unit diagonal elements of L are not stored. On entry, the array b contains the right hand sides $sub(B)$.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
$desca$	(global and local) INTEGER array, dimension ($dlen\_$). The array descriptor for the distributed matrix A .
$ipiv$	(local) INTEGER array. The dimension of $ipiv$ is $(LOCr(m\_a) + mb\_a)$. This array contains the pivoting information: local row i of the matrix was interchanged with the global row $ipiv(i)$. This array is tied to the distributed matrix A.
ib, jb	(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of the submatrix $sub(B)$, respectively.

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*.

Output Parameters

b On exit, overwritten by the solution distributed matrix *x*.
info INTEGER. If *info*=0, the execution is successful. *info* < 0:
 If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?gbtrs

Solves a system of distributed linear equations with a general band matrix, using the LU factorization computed by p?gbtrf.

Syntax

```
call psgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
laf, work, lwork, info)
```

```
call pdgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
laf, work, lwork, info)
```

```
call pcgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
laf, work, lwork, info)
```

```
call pzgbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, af,
laf, work, lwork, info)
```

Description

This routine solves a system of distributed linear equations with a general band distributed matrix $\text{sub}(A) = A(1:n, ja:ja+n-1)$ using the LU factorization computed by p?gbtrf.

The system has one of the following forms specified by *trans*:

$\text{sub}(A) * X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T * X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H * X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$.

Before calling this routine, you must call [p?gbtrf](#) to compute the *LU* factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for <i>X</i>. If <i>trans</i> = 'T', then $\text{sub}(A)^T * X = \text{sub}(B)$ is solved for <i>X</i>. If <i>trans</i> = 'C', then $\text{sub}(A)^H * X = \text{sub}(B)$ is solved for <i>X</i>.
<i>n</i>	(global) INTEGER. The number of linear equations; the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of sub-diagonals within the band of <i>A</i> ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of super-diagonals within the band of <i>A</i> ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(global) REAL for psgbtrs DOUBLE PRECISION for pdgbtrs COMPLEX for pcgbtrs DOUBLE COMPLEX for pzgbtrs. Pointers into the local memory to arrays of local dimension $a(lld\_a, LOC_c(ja+n-1))$ and $b(lld\_b, LOC_c(nrhs))$, respectively. The array <i>a</i> contains details of the <i>LU</i> factorization of the distributed band matrix <i>A</i>. On entry, the array <i>b</i> contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.

<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be $laf \geq NB \cdot (bwl + bwu) + 6 \cdot (bwl + bwu) \cdot (bwl + 2 \cdot bwu)$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The size of the <i>work</i> array, must be at least $lwork \geq nrhs \cdot (NB + 2 \cdot bwl + 4 \cdot bwu)$.

Output Parameters

<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> must be ≥ <i>desca</i> (NB). Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.
<i>b</i>	On exit, overwritten by the local pieces of the solution distributed matrix <i>x</i> .
<i>af</i>	(local) REAL for psgbtrs DOUBLE PRECISION for pdgbtrs

COMPLEX for p_{cg}btrs
DOUBLE COMPLEX for p_zgbtrs.
Array, dimension (*laf*).
Auxiliary Fillin space. Fillin is created during the factorization routine p_?gbtrf and this is stored in *af*.
Note that if a linear system is to be solved using p_?gbtrs after the factorization routine, *af* must not be altered after the factorization.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful.
info < 0:
If the *i*-th argument is an array and the *j*th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?potrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian distributed positive-definite matrix.

Syntax

```
call pspotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pcpotrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pzpotsrs(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

The routine p_?potrs solves for *x* a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is an *n*-by-*n* real symmetric or complex Hermitian positive definite distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

This routine uses Cholesky factorization

$$\text{sub}(A) = U^H * U, \text{ or } \text{sub}(A) = L * L^H$$

computed by `p?potrf`.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of sub(<i>A</i>) is stored; If <i>uplo</i> = 'L', lower triangle of sub(<i>A</i>) is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix sub(<i>A</i>) ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix sub(<i>B</i>) ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for pspotrs DOUBLE PRECISION for pdpotrs COMPLEX for pcpotrs DOUBLE COMPLEX for pzpotrs. Pointers into the local memory to arrays of local dimension <i>a</i> (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)) and <i>b</i> (<i>lld_b</i> , <i>LOCc</i> (<i>jb</i> + <i>nrhs</i> -1)), respectively. The array <i>a</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by <code>p?potrf</code> . On entry, the array <i>b</i> contains the local pieces of the right hand sides sub(<i>B</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively.

descb (global and local) `INTEGER` array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*.

Output Parameters

b Overwritten by the local pieces of the solution matrix *X*.

info `INTEGER`. If *info*=0, the execution is successful.
info < 0: if the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric/Hermitian positive-definite band matrix.

Syntax

```
call pspbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)

call pdpbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)

call pcpbtrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
             lwork, info)

call pzpbttrs( uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
              lwork, info)
```

Description

The routine `p?pbtrs` solves for *X* a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an *n*-by-*n* real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses Cholesky factorization

$\text{sub}(A) = P*U^H*U*P^T$, or $\text{sub}(A) = P*L*L^H*P^T$

computed by `p?pbtrf`.

Input Parameters

uplo (global) CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', upper triangle of $\text{sub}(A)$ is stored;
 If *uplo* = 'L', lower triangle of $\text{sub}(A)$ is stored.

n (global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

bw (global) INTEGER. The number of superdiagonals of the distributed matrix if *uplo* = 'U', or the number of subdiagonals if *uplo* = 'L' ($bw \geq 0$).

nrhs (global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).

a, b (local)
 REAL for `pspbtrs`
 DOUBLE PRECISION for `pdpbtrs`
 COMPLEX for `pcpbtrs`
 DOUBLE COMPLEX for `pzpbtrs`.
 Pointers into the local memory to arrays of local dimension $a(lld\_a, LOCC(ja+n-1))$ and $b(lld\_b, LOCC(nrhs-1))$, respectively.
 The array *a* contains the permuted triangular factor *U* or *L* from the Cholesky factorization $\text{sub}(A) = P*U^H*U*P^T$, or $\text{sub}(A) = P*L*L^H*P^T$ of the band matrix *A*, as returned by `p?pbtrf`.
 On entry, the array *b* contains the local pieces of the *n*-by-*nrhs* right hand side distributed matrix $\text{sub}(B)$.

ja (global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.
 If `desca(dtype_) = 501`, then $dlen_ \geq 7$;

	else if <code>desca(dtype_) = 1</code> , then $dlen_ \geq 9$.
<code>ib</code>	(global) INTEGER. The row index in the global array <i>B</i> indicating the first row of the submatrix <code>sub(B)</code> .
<code>descb</code>	(global and local) INTEGER array, dimension ($dlen_$). The array descriptor for the distributed matrix <i>B</i> . If <code>descb(dtype_) = 502</code> , then $dlen_ \geq 7$; else if <code>descb(dtype_) = 1</code> , then $dlen_ \geq 9$.
<code>af, work</code>	(local) Arrays, same type as <i>a</i> . The array <i>af</i> is of dimension (laf). It contains auxiliary Fillin space. Fillin is created during the factorization routine <code>p?dbtrf</code> and this is stored in <i>af</i> . The array <i>work</i> is a workspace array of dimension $lwork$.
<code>laf</code>	(local) INTEGER. The dimension of the array <i>af</i> . Must be $laf \geq nrhs*bw$. If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in <code>af(1)</code> .
<code>lwork</code>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least $lwork \geq bw^2$.

Output Parameters

<code>b</code>	On exit, if <code>info=0</code> , this array contains the local pieces of the <i>n</i> -by- <i>nrhs</i> solution distributed matrix <i>X</i> .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of $lwork$ required for optimum performance.
<code>info</code>	INTEGER. If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal distributed matrix using the factorization computed by p?pttrf.

Syntax

```
call pspttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork,
info)

call pdpttrs(n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork,
info)

call pcpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pzpttrs(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

Description

The routine p?pttrs solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the factorization

$$\text{sub}(A) = P * L * D * L^H * P^T, \text{ or } \text{sub}(A) = P * U^H * D * U * P^T$$

computed by p?pttrf.

Input Parameters

<i>uplo</i>	(global, used in complex flavors only) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored; If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix sub(<i>B</i>) (<i>nrhs</i> ≥0).
<i>d, e</i>	(local) REAL for pspttrs DOUBLE PRECISION for pdpttrs COMPLEX for pcpttrs DOUBLE COMPLEX for pzpttrs. Pointers into the local memory to arrays of dimension (<i>desca</i> (<i>nb_</i>)) each. These arrays contain details of the factorization as returned by p?pttrf
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> (<i>dtype_</i>) = 501 or 502, then <i>dlen_</i> ≥ 7; else if <i>desca</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>b</i>	(local) Same type as <i>d, e</i> . Pointer into the local memory to an array of local dimension <i>b</i> (<i>lld_b</i> , <i>LOCc</i> (<i>nrhs</i>)). On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix sub(<i>B</i>).
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb</i> (<i>dtype_</i>) = 502, then <i>dlen_</i> ≥ 7; else if <i>descb</i> (<i>dtype_</i>) = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) REAL for pspttrs DOUBLE PRECISION for pdpttrs COMPLEX for pcpttrs DOUBLE COMPLEX for pzpttrs.

Arrays of dimension (*laf*) and (*lwork*), respectively. The array *af* contains auxiliary Fillin space. Fillin is created during the factorization routine `p?pttrf` and this is stored in *af*.

The array *work* is a workspace array.

laf (local) INTEGER. The dimension of the array *af*.

Must be $laf \geq NB+2$.

If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*(1).

lwork (local or global) INTEGER. The size of the array *work*, must be at least

$lwork \geq (10+2*\min(100,nrhs))*NPCOL+4*nrhs$.

Output Parameters

b On exit, this array contains the local pieces of the solution distributed matrix *X*.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful.
info < 0:
 if the *i*-th argument is an array and the *j*-th entry had an illegal value, then $info = -(i*100+j)$;
 if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.

p?dttrs

Solves a system of linear equations with a diagonally dominant-like tridiagonal distributed matrix using the factorization computed by p?dttrf.

Syntax

```
call psdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pddttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pcdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzdttrs(trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

The routine p?dttrs solves for X one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = (1:n, ja:ja+n-1)$; is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by p?dttrf.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If *trans* = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .
If *trans* = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X .
If *trans* = 'C', then $(\text{sub}(A))^H * X = \text{sub}(B)$ is solved for X .

<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>dl, d, du</i>	(local) REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs DOUBLE COMPLEX for pzdttrs. Pointers to the local arrays of dimension $(\text{desca}(nb\_))$ each. On entry, these arrays contain details of the factorization. Globally, $dl(1)$ and $du(n)$ are not referenced; dl and du must be aligned with d .
<i>ja</i>	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A . If $\text{desca}(dtype_) = 501$ or 502 , then $dlen_ \geq 7$; else if $\text{desca}(dtype_) = 1$, then $dlen_ \geq 9$.
<i>b</i>	(local) Same type as d . Pointer into the local memory to an array of local dimension $b(lld\_b, LOCC(nrhs))$. On entry, the array b contains the local pieces of the n -by- $nrhs$ right hand side distributed matrix $\text{sub}(B)$.
<i>ib</i>	(global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
<i>descb</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix B . If $\text{descb}(dtype_) = 502$, then $dlen_ \geq 7$; else if $\text{descb}(dtype_) = 1$, then $dlen_ \geq 9$.

<i>af, work</i>	(local) REAL for psdtttrs DOUBLE PRECISION for pddtttrs COMPLEX for pcdtttrs DOUBLE COMPLEX for pzdtttrs. Arrays of dimension (<i>laf</i>) and (<i>lwork</i>), respectively. The array <i>af</i> contains auxiliary Fillin space. Fillin is created during the factorization routine p?dttrf and this is stored in <i>af</i>. If a linear system is to be solved using p?dttrs after the factorization routine, <i>af</i> must not be altered. The array <i>work</i> is a workspace array.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i>. Must be $laf \geq NB * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i>, must be at least $lwork \geq 10 * NPCOL + 4 * nrhs$.

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>x</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i>=0, the execution is successful. <i>info</i> < 0: if the <i>i</i>th argument is an array and the <i>j</i>-th entry had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.

p?dbtrs

Solves a system of linear equations with a diagonally dominant-like banded distributed matrix using the factorization computed by p?dbtrf.

Syntax

```
call psdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pddbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pcdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzdbtrs(trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

The routine p?dbtrs solves for X one of the systems of equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like banded distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This routine uses the LU factorization computed by p?dbtrf.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Indicates the form of the equations:
 If *trans* = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X .
 If *trans* = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X .
 If *trans* = 'C', then $(\text{sub}(A))^H * X = \text{sub}(B)$ is solved for X .

<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) INTEGER. The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for psdbtrs DOUBLE PRECISION for pddbtrs COMPLEX for pcdbtrs DOUBLE COMPLEX for pzdbtrs. Pointers into the local memory to arrays of local dimension $a(lld\_a, LOCC(ja+n-1))$ and $b(lld\_b, LOCC(nrhs))$, respectively. On entry, the array <i>a</i> contains details of the <i>LU</i> factorization of the band matrix A , as computed by p?dbtrf. On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix $\text{sub}(B)$.
<i>ja</i>	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix A . If $desca(dtype\_)$ = 501, then $dlen\_ \geq 7$; else if $desca(dtype\_)$ = 1, then $dlen\_ \geq 9$.
<i>ib</i>	(global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).

<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb(dtype_)</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>descb(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) REAL for psdbtrs DOUBLE PRECISION for pddbtrs COMPLEX for pcdbtrs DOUBLE COMPLEX for pzdbtrs. Arrays of dimension (<i>laf</i>) and (<i>lwork</i>), respectively The array <i>af</i> contains auxiliary Fillin space. Fillin is created during the factorization routine <i>p?dbtrf</i> and this is stored in <i>af</i> . The array <i>work</i> is a workspace array.
<i>laf</i>	(local) INTEGER. The dimension of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>lwork</i>	(local or global) INTEGER. The size of the array <i>work</i> , must be at least $lwork \geq (\max(bwl, bwu))^2$.

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

p?trtrs

Solves a system of linear equations with a triangular distributed matrix.

Syntax

```
call pstrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)

call pdtrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)

call pctrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)

call pztrtrs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
info)
```

Description

This routine solves for x one of the following systems of linear equations:

$$\text{sub}(A) * X = \text{sub}(B),$$

$$(\text{sub}(A))^T * X = \text{sub}(B), \text{ or}$$

$$(\text{sub}(A))^H * X = \text{sub}(B),$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a triangular distributed matrix of order n , and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

A check is made to verify that $\text{sub}(A)$ is nonsingular.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Indicates whether $\text{sub}(A)$ is upper or lower triangular: If <i>uplo</i> = 'U', then $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', then $\text{sub}(A)$ is lower triangular.
<i>trans</i>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for x . If <i>trans</i> = 'T', then $\text{sub}(A)^T * X = \text{sub}(B)$ is solved for x . If <i>trans</i> = 'C', then $\text{sub}(A)^H * X = \text{sub}(B)$ is solved for x .

If $trans = 'C'$, then $sub(A)^H X = sub(B)$ is solved for X .

diag (global) CHARACTER*1. Must be 'N' or 'U'.
 If $diag = 'N'$, then $sub(A)$ is not a unit triangular matrix.
 If $diag = 'U'$, then $sub(A)$ is unit triangular.

n (global) INTEGER. The order of the distributed submatrix $sub(A)$ ($n \geq 0$).

nrhs (global) INTEGER. The number of right-hand sides; i.e., the number of columns of the distributed matrix $sub(B)$ ($nrhs \geq 0$).

a, b (local)
 REAL for pstrtrs
 DOUBLE PRECISION for pdtrtrs
 COMPLEX for pctrtrs
 DOUBLE COMPLEX for pztrtrs.
 Pointers into the local memory to arrays of local dimension $a(lld\_a, LOCC(ja+n-1))$ and $b(lld\_b, LOCC(jb+nrhs-1))$, respectively.
 The array a contains the local pieces of the distributed triangular matrix $sub(A)$.
 If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular matrix, and the strictly lower triangular part of $sub(A)$ is not referenced.
 If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $sub(A)$ is not referenced.
 If $diag = 'U'$, the diagonal elements of $sub(A)$ are also not referenced and are assumed to be 1.
 On entry, the array b contains the local pieces of the right hand side distributed matrix $sub(B)$.

ia, ja (global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $sub(A)$, respectively.

desca (global and local) INTEGER array, dimension ($dlen\_$). The array descriptor for the distributed matrix A .

<i>ib, jb</i>	(global) <code>INTEGER</code> . The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <code>sub(B)</code> , respectively.
<i>descb</i>	(global and local) <code>INTEGER</code> array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, <code>sub(B)</code> is overwritten by the solution matrix <i>X</i> .
<i>info</i>	<code>INTEGER</code> . If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> ; <i>info</i> > 0: if <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <code>sub(A)</code> is zero, indicating that the submatrix is singular and the solutions <i>X</i> have not been computed.

Routines for Estimating the Condition Number

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

p?gecon

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

Syntax

```
call psgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
             liwork, info)

call pdgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
             liwork, info)

call pcgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
             lrwork, info)

call pzgecon( norm, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
             lrwork, info)
```

Description

This routine estimates the reciprocal of the condition number of a general distributed real/complex matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ in either the 1-norm or infinity-norm, using the *LU* factorization computed by [p?getrf](#).

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|\text{sub}(A)\| \times \|(\text{sub}(A))^{-1}\|}$$

Input Parameters

norm (global) CHARACTER*1. Must be '1' or 'O' or 'I'.
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required.
 If *norm* = '1' or 'O', then the 1-norm is used;
 If *norm* = 'I', then the infinity-norm is used.

<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psgecon DOUBLE PRECISION for pdgecon COMPLEX for pcgecon DOUBLE COMPLEX for pzgecon. Pointer into the local memory to an array of dimension $a(lld\_a, LOCC(ja+n-1))$. The array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of <i>L</i> are not stored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors. If <i>norm</i> = '1' or 'O', the 1-norm of the original distributed matrix $\text{sub}(A)$; If <i>norm</i> = 'I', the infinity-norm of the original distributed matrix $\text{sub}(A)$.
<i>work</i>	(local) REAL for psgecon DOUBLE PRECISION for pdgecon COMPLEX for pcgecon DOUBLE COMPLEX for pzgecon. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least

$$lwork \geq 2*LOCr(n+mod(ia-1,mb\_a))+$$

$$2*LOCc(n+mod(ja-1,nb\_a))+max(2, max(nb\_a*max(1,$$

$$ceil(NPROW-1, NPCOL)),$$

$$LOCc(n+mod(ja-1,nb\_a))+nb\_a*max(1, ceil(NPCOL-1,$$

$$NPROW))).$$

For complex flavors:

lwork must be at least

$$lwork \geq 2*LOCr(n+mod(ia-1,mb\_a))+max(2,$$

$$max(nb\_a*ceil(NPROW-1, NPCOL),$$

$$LOCc(n+mod(ja-1,nb\_a))+ nb\_a*ceil(NPCOL-1,$$

$$NPROW))).$$

LOCr and *LOCc* values can be computed using the ScaLAPACK tool function `numroc`; *NPROW* and *NPCOL* can be determined by calling the subroutine `blacs_gridinfo`.

iwork (local) INTEGER. Workspace array, DIMENSION (*liwork*). Used in real flavors only.

liwork (local or global) INTEGER. The dimension of the array *iwork*; used in real flavors only. Must be at least

$$liwork \geq LOCr(n+mod(ia-1,mb\_a)).$$

rwork (local) REAL for `pcgecon`
DOUBLE PRECISION for `pzgecon`
Workspace array, DIMENSION (*lrwork*). Used in complex flavors only.

lrwork (local or global) INTEGER. The dimension of the array *rwork*; used in complex flavors only. Must be at least

$$lrwork \geq 2*LOCc(n+mod(ja-1,nb\_a)).$$

Output Parameters

rcond (global) REAL for single precision flavors.
DOUBLE PRECISION for double precision flavors.
The reciprocal of the condition number of the distributed matrix `sub(A)`. See Description.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

<code>iwork(1)</code>	On exit, <code>iwork(1)</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors).
<code>rwork(1)</code>	On exit, <code>rwork(1)</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors).
<code>info</code>	(global) INTEGER. If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?pocon

Estimates the reciprocal of the condition number (in the 1 - norm) of a symmetric / Hermitian positive-definite distributed matrix.

Syntax

```
call pspcocon( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
               liwork, info)

call pdpcocon( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, iwork,
               liwork, info)

call pcpcocn( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
               lrwork, info)

call pzpcocn( uplo, n, a, ia, ja, desca, anorm, rcond, work, lwork, rwork,
               lrwork, info)
```

Description

This routine estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

An estimate is obtained for $||(\text{sub}(A))^{-1}||$, and the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the factor stored in sub(A) is upper or lower triangular. If <i>uplo</i> = 'U', sub(A) stores the upper triangular factor U of the Cholesky factorization $sub(A) = U^H * U$. If <i>uplo</i> = 'L', sub(A) stores the lower triangular factor L of the Cholesky factorization $sub(A) = L * L^H$.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix sub(A) ($n \geq 0$).
<i>a</i>	(local) REAL for pspocon DOUBLE PRECISION for pdpocon COMPLEX for pcpocon DOUBLE COMPLEX for pzpocon. Pointer into the local memory to an array of dimension $a(lld\_a, LOCC(ja+n-1))$. The array <i>a</i> contains the local pieces of the factors L or U from the Cholesky factorization $sub(A) = U^H * U$, or $sub(A) = L * L^H$, as computed by p?potrf.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(A), respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>anorm</i>	(global) REAL for single precision flavors, DOUBLE PRECISION for double precision flavors. The 1-norm of the symmetric/Hermitian distributed matrix sub(A).
<i>work</i>	(local) REAL for pspocon

	DOUBLE PRECISION for pdpocon COMPLEX for pcpocon DOUBLE COMPLEX for pzpocon. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb\_a)) + 2*LOCc(n+mod(ja-1,nb\_a)) + \max(2, \max(nb\_a*ceil(NPROW-1, NPCOL), LOCc(n+mod(ja-1,nb\_a)) + nb\_a*ceil(NPCOL-1, NPROW)))$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb\_a)) + \max(2, \max(nb\_a*\max(1,ceil(NPROW-1, NPCOL)), LOCc(n+mod(ja-1,nb\_a)) + nb\_a*\max(1,ceil(NPCOL-1, NPROW))))$
<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ia-1,mb\_a))$.
<i>rwork</i>	(local) REAL for pcpocon DOUBLE PRECISION for pzpocon Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq 2*LOCc(n+mod(ja-1,nb\_a))$.

Output Parameters

<i>rcond</i>	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.

	The reciprocal of the condition number of the distributed matrix $\text{sub}(A)$.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>iwork(1)</code>	On exit, <code>iwork(1)</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors).
<code>rwork(1)</code>	On exit, <code>rwork(1)</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors).
<code>info</code>	(global) INTEGER. If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <code>info = -(i*100+j)</code> ; if the <i>i</i> th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?trcon

Estimates the reciprocal of the condition number of a triangular distributed matrix in either 1-norm or infinity-norm.

Syntax

```
call pstrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
iwork, liwork, info)

call pdtrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
iwork, liwork, info)

call pctrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
rwork, lrwork, info)

call pztrcon( norm, uplo, diag, n, a, ia, ja, desca, rcond, work, lwork,
rwork, lrwork, info)
```

Description

This routine estimates the reciprocal of the condition number of a triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, in either the 1-norm or the infinity-norm.

The norm of $\text{sub}(A)$ is computed and an estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, then the reciprocal of the condition number is computed as

$$rcond = \frac{1}{\|sub(A)\| \times \|(sub(A))^{-1}\|}$$

Input Parameters

<i>norm</i>	(global) CHARACTER*1. Must be '1' or 'O' or 'I'. Specifies whether the 1-norm condition number or the infinity-norm condition number is required. If <i>norm</i> = '1' or 'O', then the 1-norm is used; If <i>norm</i> = 'I', then the infinity-norm is used.
<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', sub(<i>A</i>) is upper triangular. If <i>uplo</i> = 'L', sub(<i>A</i>) is lower triangular.
<i>diag</i>	(global) CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', sub(<i>A</i>) is non-unit triangular. If <i>diag</i> = 'U', sub(<i>A</i>) is unit triangular.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix sub(<i>A</i>), (<i>n</i>≥0).
<i>a</i>	(local) REAL for pstrcon DOUBLE PRECISION for pdtrcon COMPLEX for petrcon DOUBLE COMPLEX for pztrcon. Pointer into the local memory to an array of dimension <i>a</i>(<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)). The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced. If <i>diag</i> = 'U', the diagonal elements of sub(<i>A</i>) are also not referenced and are assumed to be 1.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for pstrcon DOUBLE PRECISION for pdtrcon COMPLEX for pctrcon DOUBLE COMPLEX for pztrcon. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb\_a))+$ $LOCc(n+\text{mod}(ja-1,nb\_a))+\max(2,$ $\max(nb\_a*\max(1,\text{ceil}(NPROW-1,NPCOL)),$ $LOCc(n+\text{mod}(ja-1,nb\_a))+nb\_a*\max(1,\text{ceil}(NPCOL-1,$ $NPROW))).$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb\_a))+\max(2,$ $\max(nb\_a*\text{ceil}(NPROW-1,NPCOL),$ $LOCc(n+\text{mod}(ja-1,nb\_a))+nb\_a*\text{ceil}(NPCOL-1,$ $NPROW))).$
<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+\text{mod}(ia-1,mb\_a)).$
<i>rwork</i>	(local) REAL for pcpccon DOUBLE PRECISION for pzpccon Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least

$$lrwork \geq LOCC(n + \text{mod}(ja-1, nb\_a)).$$

Output Parameters

<i>rcond</i>	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The reciprocal of the condition number of the distributed matrix sub(A).
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Refining the Solution and Estimating Its Error

This section describes the ScaLAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Solving Systems of Linear Equations](#)).

p?gerfs

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

```
call psgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork,
info)
```

```
call pdgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork,
info)
```

```
call pcgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork,
info)
```

```
call pzgerfs(trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf, ipiv,
b, ib, jb, descb, x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork,
info)
```

Description

This routine improves the computed solution to one of the systems of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$

$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B),$ or

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ and provides error bounds and backward error estimates for the solution.

Here $\text{sub}(A) = A(\text{ia}:\text{ia}+\text{n}-1, \text{ja}:\text{ja}+\text{n}-1)$, $\text{sub}(B) = B(\text{ib}:\text{ib}+\text{n}-1, \text{jb}:\text{jb}+\text{nrhs}-1)$, and $\text{sub}(X) = X(\text{ix}:\text{ix}+\text{n}-1, \text{jx}:\text{jx}+\text{nrhs}-1)$.

Input Parameters

trans (global) CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Specifies the form of the system of equations:
 If *trans* = 'N', the system has the form $\text{sub}(A) * \text{sub}(X)$
 = $\text{sub}(B)$ (No transpose);

	If $trans = 'T'$, the system has the form $sub(A)^T * sub(X) = sub(B)$ (Transpose); If $trans = 'C'$, the system has the form $sub(A)^H * sub(X) = sub(B)$ (Conjugate transpose).
n	(global) INTEGER. The order of the distributed submatrix $sub(A)$ ($n \geq 0$).
$nrhs$	(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices $sub(B)$ and $sub(X)$ ($nrhs \geq 0$).
a, af, b, x	(local) REAL for psgerfs DOUBLE PRECISION for pdgerfs COMPLEX for pcgerfs DOUBLE COMPLEX for pzgerfs. Pointers into the local memory to arrays of local dimension $a(lld\_a, LOCC(ja+n-1))$, $af(lld\_af, LOCC(jaf+n-1))$, $b(lld\_b, LOCC(jb+nrhs-1))$, and $x(lld\_x, LOCC(jx+nrhs-1))$, respectively. The array a contains the local pieces of the distributed matrix $sub(A)$. The array af contains the local pieces of the distributed factors of the matrix $sub(A) = P * L * U$ as computed by p?getrf. The array b contains the local pieces of the distributed matrix of right hand sides $sub(B)$. On entry, the array x contains the local pieces of the distributed solution matrix $sub(X)$.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
$desca$	(global and local) INTEGER array, dimension ($dlen\_$). The array descriptor for the distributed matrix A .
iaf, jaf	(global) INTEGER. The row and column indices in the global array AF indicating the first row and the first column of the submatrix $sub(AF)$, respectively.

<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>ipiv</i>	(local) INTEGER. Array, dimension $LOCr(m_{af} + m_{b_{af}})$. This array contains pivoting information as computed by p?getrf . If <i>ipiv</i> (<i>i</i>)= <i>j</i> , then the local row <i>i</i> was swapped with the global row <i>j</i> . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <i>psgerfs</i> DOUBLE PRECISION for <i>pdgerfs</i> COMPLEX for <i>pcgerfs</i> DOUBLE COMPLEX for <i>pzgerfs</i> . The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb_a))$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb_a))$
<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.
<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least

liwork $\geq LOCr(n+\text{mod}(ib-1,mb\_b))$.

rwork (local) REAL for `pcgerfs`
 DOUBLE PRECISION for `pzgerfs`
 Workspace array, DIMENSION (*lrwork*). Used in complex flavors only.

lrwork (local or global) INTEGER. The dimension of the array *rwork*; used in complex flavors only. Must be at least $liwork \geq LOCr(n+\text{mod}(ib-1,mb\_b))$.

Output Parameters

x On exit, contains the improved solution vectors.

ferr, *berr* REAL for single precision flavors.
 DOUBLE PRECISION for double precision flavors.
 Arrays, dimension $LOCc(jb+nrhs-1)$ each.
 The array *ferr* contains the estimated forward error bound for each solution vector of `sub(x)`.
 If `XTRUE` is the true solution corresponding to `sub(x)`, *ferr* is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - XTRUE)$ divided by the magnitude of the largest element in `sub(x)`. The estimate is as reliable as the estimate for `rcond`, and is almost always a slight overestimate of the true error.
 This array is tied to the distributed matrix *x*.
 The array *berr* contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of `sub(A)` or `sub(B)` that makes `sub(x)` an exact solution). This array is tied to the distributed matrix *x*.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1) On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance (for real flavors).

rwork(1) On exit, *rwork*(1) contains the minimum value of *lrwork* required for optimum performance (for complex flavors).

info (global) INTEGER. If *info*=0, the execution is successful.

info < 0:

If the *i*th argument is an array and the *j*th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?porfs

Improves the computed solution to a system of linear equations with symmetric/Hermitian positive definite distributed matrix and provides error bounds and backward error estimates for the solution.

Syntax

```

```

Description

The routine p?porfs improves the computed solution to the system of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a real symmetric or complex Hermitian positive definite distributed matrix and

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1),$$

$$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+\text{nrhs}-1)$$

are right-hand side and solution submatrices, respectively. This routine also provides error bounds and backward error estimates for the solution.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$).
<i>a, af, b, x</i>	(local) REAL for psporfs DOUBLE PRECISION for pdporfs COMPLEX for pcporfs DOUBLE COMPLEX for pzporfs. Pointers into the local memory to arrays of local dimension $a(lld\_a, LOCC(ja+n-1))$, $af(lld\_af, LOCC(ja+n-1))$, $b(lld\_b, LOCC(jb+nrhs-1))$, and $x(lld\_x, LOCC(jx+nrhs-1))$, respectively. The array <i>a</i> contains the local pieces of the n-by-n symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. The array <i>af</i> contains the factors L or U from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by p?potrf. On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$. On entry, the array <i>x</i> contains the local pieces of the solution vectors $\text{sub}(X)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array <i>AF</i> indicating the first row and the first column of the submatrix <i>sub(AF)</i> , respectively.
<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>X</i> indicating the first row and the first column of the submatrix <i>sub(X)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) REAL for psporfs DOUBLE PRECISION for pdporfs COMPLEX for pcporfs DOUBLE COMPLEX for pzporfs. The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> . For real flavors: <i>lwork</i> must be at least $lwork \geq 3*LOCr(n+\text{mod}(ia-1,mb\_a))$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb\_a))$
<i>iwork</i>	(local) INTEGER. Workspace array, DIMENSION (<i>liwork</i>). Used in real flavors only.

<i>liwork</i>	(local or global) INTEGER. The dimension of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ib-1,mb\_b))$.
<i>rwork</i>	(local) REAL for pcporfs DOUBLE PRECISION for pzpofrs Workspace array, DIMENSION (<i>lrwork</i>). Used in complex flavors only.
<i>lrwork</i>	(local or global) INTEGER. The dimension of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n+mod(ib-1,mb\_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCc(jb+nrhs-1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of $sub(X)$. If <i>XTRUE</i> is the true solution corresponding to $sub(X)$, <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(sub(X) - XTRUE)$ divided by the magnitude of the largest element in $sub(X)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>x</i> . The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $sub(A)$ or $sub(B)$ that makes $sub(x)$ an exact solution). This array is tied to the distributed matrix <i>x</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).

info (global) INTEGER. If *info*=0, the execution is successful.
info < 0:
 If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?trrfs

Provides error bounds and backward error estimates for the solution to a system of linear equations with a distributed triangular coefficient matrix.

Syntax

```
call pstrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pdtrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, iwork, liwork, info)

call pctrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)

call pztrrfs(uplo, trans, diag, n, nrhs, a, ia, ja, desca, b, ib, jb, descb,
x, ix, jx, descx, ferr, berr, work, lwork, rwork, lrwork, info)
```

Description

The routine p?trrfs provides error bounds and backward error estimates for the solution to one of the systems of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$

$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B),$ or

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B),$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a triangular matrix,

$\text{sub}(B) = B(ib:ib+n-1, jb:jb+nrhs-1),$ and

$\text{sub}(X) = X(ix:ix+n-1, jx:jx+nrhs-1).$

The solution matrix x must be computed by `p?trtrs` or some other means before entering this routine. The routine `p?trrfs` does not do iterative refinement because doing so cannot improve the backward error.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Must be 'U' or 'L'. If <code>uplo</code> = 'U', <code>sub(A)</code> is upper triangular. If <code>uplo</code> = 'L', <code>sub(A)</code> is lower triangular.
<code>trans</code>	(global) CHARACTER*1. Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <code>trans</code> = 'N', the system has the form <code>sub(A) * sub(X)</code> = <code>sub(B)</code> (No transpose); If <code>trans</code> = 'T', the system has the form <code>sub((A)^T * sub(X)</code> = <code>sub(B)</code> (Transpose); If <code>trans</code> = 'C', the system has the form <code>sub(A)^H * sub(X)</code> = <code>sub(B)</code> (Conjugate transpose).
<code>diag</code>	CHARACTER*1. Must be 'N' or 'U'. If <code>diag</code> = 'N', then <code>sub(A)</code> is non-unit triangular. If <code>diag</code> = 'U', then <code>sub(A)</code> is unit triangular.
<code>n</code>	(global) INTEGER. The order of the distributed matrix <code>sub(A)</code> ($n \geq 0$).
<code>nrhs</code>	(global) INTEGER. The number of right-hand sides, that is, the number of columns of the matrices <code>sub(B)</code> and <code>sub(X)</code> ($nrhs \geq 0$).
<code>a, b, x</code>	(local) REAL for <code>pstrrfs</code> DOUBLE PRECISION for <code>pdtrrfs</code> COMPLEX for <code>pctrfs</code> DOUBLE COMPLEX for <code>pztrrfs</code> . Pointers into the local memory to arrays of local dimension <code>a(lld_a, LOCC(ja+n-1))</code> , <code>b(lld_b, LOCC(jb+nrhs-1))</code> , and <code>x(lld_x, LOCC(jx+nrhs-1))</code> , respectively. The array <code>a</code> contains the local pieces of the original triangular distributed matrix <code>sub(A)</code> .

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *sub(A)* contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *sub(A)* contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.

If *diag* = 'U', the diagonal elements of *sub(A)* are also not referenced and are assumed to be 1.

On entry, the array *b* contains the local pieces of the distributed matrix of right hand sides *sub(B)*.

On entry, the array *x* contains the local pieces of the solution vectors *sub(X)*.

ia, ja (global) INTEGER. The row and column indices in the global array *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *A*.

ib, jb (global) INTEGER. The row and column indices in the global array *B* indicating the first row and the first column of the submatrix *sub(B)*, respectively.

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*.

ix, jx (global) INTEGER. The row and column indices in the global array *X* indicating the first row and the first column of the submatrix *sub(X)*, respectively.

descx (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *X*.

work (local)
 REAL for *pstrrfs*
 DOUBLE PRECISION for *pdtrrfs*
 COMPLEX for *pctrfs*
 DOUBLE COMPLEX for *pztrfs*.
 The array *work* of dimension (*lwork*) is a workspace array.

lwork (local) INTEGER. The dimension of the array *work*.

For real flavors:

	$lwork$ must be at least $lwork \geq 3*LOCr(n+\text{mod}(ia-1,mb\_a))$ For complex flavors: $lwork$ must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1,mb\_a))$
$iwork$	(local) INTEGER. Workspace array, DIMENSION ($liwork$). Used in real flavors only.
$liwork$	(local or global) INTEGER. The dimension of the array $iwork$; used in real flavors only. Must be at least $liwork \geq LOCr(n+\text{mod}(ib-1,mb\_b))$.
$rwork$	(local) REAL for pctrdfs DOUBLE PRECISION for pztrdfs Workspace array, DIMENSION ($lrwork$). Used in complex flavors only.
$lrwork$	(local or global) INTEGER. The dimension of the array $rwork$; used in complex flavors only. Must be at least $lrwork \geq LOCr(n+\text{mod}(ib-1,mb\_b))$.

Output Parameters

$ferr, berr$	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCc(jb+nrhs-1)$ each. The array $ferr$ contains the estimated forward error bound for each solution vector of $\text{sub}(x)$. If $XTRUE$ is the true solution corresponding to $\text{sub}(x)$, $ferr$ is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(x) - XTRUE)$ divided by the magnitude of the largest element in $\text{sub}(x)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix x .

	The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of $\text{sub}(A)$ or $\text{sub}(B)$ that makes $\text{sub}(X)$ an exact solution). This array is tied to the distributed matrix <i>X</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	On exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> (1)	On exit, <i>rwork</i> (1) contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Routines for Matrix Inversion

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

p?getri

Computes the inverse of a LU-factored distributed matrix.

Syntax

```
call psgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pdgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pcgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
call pzgetri(n, a, ia, ja, desca, ipiv, work, lwork, iwork, liwork, info)
```

Description

This routine computes the inverse of a general distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ using the LU factorization computed by `p?getrf`. This method inverts U and then computes the inverse of $\text{sub}(A)$ by solving the system

$$\text{inv}(\text{sub}(A)) * L = \text{inv}(U)$$

for $\text{inv}(\text{sub}(A))$.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for <code>psgetri</code> DOUBLE PRECISION for <code>pdgetri</code> COMPLEX for <code>pcgetri</code> DOUBLE COMPLEX for <code>pzgetri</code> . Pointer into the local memory to an array of local dimension $a(\text{lld\_a}, \text{LOCc}(\text{ja}+n-1))$. On entry, the array <i>a</i> contains the local pieces of the L and U obtained by the factorization $\text{sub}(A) = P * L * U$ computed by <code>p?getrf</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <code>psgetri</code> DOUBLE PRECISION for <code>pdgetri</code> COMPLEX for <code>pcgetri</code> DOUBLE COMPLEX for <code>pzgetri</code> . The array <i>work</i> of dimension (<i>lwork</i>) is a workspace array.
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> must be at least $\text{lwork} \geq \text{LOCr}(n + \text{mod}(\text{ia}-1, \text{mb\_a})) * \text{nb\_a}$.

The array *work* is used to keep at most an entire column block of sub(*A*).

iwork (local) INTEGER. Workspace array used for physically transposing the pivots, DIMENSION (*liwork*).

liwork (local or global) INTEGER. The dimension of the array *iwork*. The minimal value *liwork* of is determined by the following code:

```
if NPROW == NPCOL then
    liwork = LOCC(n_a + mod(ja-1,nb_a)) + nb_a
else
    liwork = LOCC(n_a + mod(ja-1,nb_a)) +
    max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)),nb_a)
end if
```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

Output Parameters

ipiv (local) INTEGER.
Array, dimension (*LOCr(m_a) + mb_a*).
This array contains the pivoting information.
If *ipiv*(*i*)=*j*, then the local row *i* was swapped with the global row *j*.
This array is tied to the distributed matrix *A*.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

iwork(1) On exit, *iwork*(1) contains the minimum value of *liwork* required for optimum performance.

info (global) INTEGER. If *info*=0, the execution is successful.
info < 0:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = i$, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?potri

Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.

Syntax

```
call pspotri(uplo, n, a, ia, ja, desca, info)
call pdpotri(uplo, n, a, ia, ja, desca, info)
call pcpotri(uplo, n, a, ia, ja, desca, info)
call pzpotri(uplo, n, a, ia, ja, desca, info)
```

Description

This routine computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by p?potrf.

Input Parameters

$uplo$	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If $uplo = 'U'$, upper triangle of $\text{sub}(A)$ is stored. If $uplo = 'L'$, lower triangle of $\text{sub}(A)$ is stored.
n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).

<i>a</i>	(local) REAL for pspotri DOUBLE PRECISION for pdpotri COMPLEX for pcpotri DOUBLE COMPLEX for pzpotri. Pointer into the local memory to an array of local dimension $a(lld\_a, LOCC(ja+n-1))$. On entry, the array <i>a</i> contains the local pieces of the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by p?potrf.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i>.

Output Parameters

<i>a</i>	On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of sub(<i>A</i>).
<i>info</i>	(global) INTEGER. If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. <i>info</i> > 0: If <i>info</i> = <i>i</i>, the (<i>i</i>, <i>i</i>) element of the factor <i>U</i> or <i>L</i> is zero, and the inverse could not be computed.

p?trtri

Computes the inverse of a triangular distributed matrix.

Syntax

```
call pstrtri(uplo, diag, n, a, ia, ja, desca, info)
call pdtrtri(uplo, diag, n, a, ia, ja, desca, info)
call pctrtri(uplo, diag, n, a, ia, ja, desca, info)
call pztrtri(uplo, diag, n, a, ia, ja, desca, info)
```

Description

This routine computes the inverse of a real or complex upper or lower triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Must be 'U' or 'L'. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. Specifies whether or not the distributed matrix $\text{sub}(A)$ is unit triangular. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pstrtri DOUBLE PRECISION for pdtrtri COMPLEX for pctrtri DOUBLE COMPLEX for pztrtri.

Pointer into the local memory to an array of local dimension
 $a(lld\_a, LOCC(ja+n-1))$.

The array a contains the local pieces of the triangular distributed matrix $\text{sub}(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix to be inverted, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A .

Output Parameters

a

On exit, overwritten by the (triangular) inverse of the original matrix.

$info$

(global) INTEGER. If $info=0$, the execution is successful.

$info < 0$:

If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = k$, $A(ia+k-1, ja+k-1)$ is exactly zero. The triangular matrix $\text{sub}(A)$ is singular and its inverse can not be computed.

Routines for Matrix Equilibration

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ

Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

```
call psgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pdgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pcgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
call pzgeequ(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, info)
```

Description

This routine computes row and column scalings intended to equilibrate an m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

$r(i)$ and $c(j)$ are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of $\text{sub}(A)$ but works well in practice.

The auxiliary function p?laqge uses scaling factors computed by p?geequ to scale a general rectangular matrix.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for psgeequ DOUBLE PRECISION for pdgeequ

COMPLEX for pcgeequ
 DOUBLE COMPLEX for pzgeequ .
 Pointer into the local memory to an array of local dimension
 $a(lld\_a, LOCc(ja+n-1))$.
 The array a contains the local pieces of the m -by- n
 distributed matrix whose equilibration factors are to be
 computed.

ia, ja (global) INTEGER. The row and column indices in the global
 array A indicating the first row and the first column of the
 submatrix $\text{sub}(A)$, respectively.

$desca$ (global and local) INTEGER array, dimension $(dlen\_)$. The
 array descriptor for the distributed matrix A .

Output Parameters

r, c (local) REAL for single precision flavors;
 DOUBLE PRECISION for double precision flavors.
 Arrays, dimension $LOCr(m\_a)$ and $LOCc(n\_a)$, respectively.
 If $info = 0$, or $info > ia+m-1$, the array r ($ia:ia+m-1$)
 contains the row scale factors for $\text{sub}(A)$. r is aligned with
 the distributed matrix A , and replicated across every process
 column. r is tied to the distributed matrix A .
 If $info = 0$, the array c ($ja:ja+n-1$) contains the column
 scale factors for $\text{sub}(A)$. c is aligned with the distributed
 matrix A , and replicated down every process row. c is tied
 to the distributed matrix A .

$rowcnd, colcnd$ (global) REAL for single precision flavors;
 DOUBLE PRECISION for double precision flavors.
 If $info = 0$ or $info > ia+m-1$, $rowcnd$ contains the ratio
 of the smallest $r(i)$ to the largest $r(i)$ ($ia \leq i \leq$
 $ia+m-1$). If $rowcnd \geq 0.1$ and $amax$ is neither too large
 nor too small, it is not worth scaling by r ($ia:ia+m-1$).
 If $info = 0$, $colcnd$ contains the ratio of the smallest $c(j)$
 to the largest $c(j)$ ($ja \leq j \leq ja+n-1$).

If $colcnd \geq 0.1$, it is not worth scaling by $c(ja:ja+n-1)$.

$amax$ (global) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.
 Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

info (global) INTEGER. If *info*=0, the execution is successful.
info < 0:
 If the *i*th argument is an array and the *j*th entry had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.
info > 0:
 If *info* = *i* and
 $i \leq m$, the *i*th row of the distributed matrix *sub(A)* is exactly zero;
 $i > m$, the (*i-m*)th column of the distributed matrix *sub(A)* is exactly zero.

p?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

Syntax

```
call pspoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pdpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pcpcpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
call pzpcpoequ(n, a, ia, ja, desca, sr, sc, scond, amax, info)
```

Description

This routine computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ and reduce its condition number (with respect to the two-norm). The output arrays *sr* and *sc* return the row and column scale factors

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled distributed matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has ones on the diagonal.

This choice of sr and sc puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for <code>pspoequ</code> DOUBLE PRECISION for <code>pdpoequ</code> COMPLEX for <code>pcpoequ</code> DOUBLE COMPLEX for <code>pzpoequ</code> . Pointer into the local memory to an array of local dimension $a(\text{lld\_a}, \text{LOCc}(ja+n-1))$. The array a contains the n -by- n symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array, dimension (dlen_) . The array descriptor for the distributed matrix A .

Output Parameters

sr, sc	(local) REAL for single precision flavors;

DOUBLE PRECISION for double precision flavors.
 Arrays, dimension $LOCr(m_a)$ and $LOCc(n_a)$, respectively.
 If $info = 0$, the array $sr(ia:ia+n-1)$ contains the row scale factors for $sub(A)$. sr is aligned with the distributed matrix A , and replicated across every process column. sr is tied to the distributed matrix A .
 If $info = 0$, the array $sc(ja:ja+n-1)$ contains the column scale factors for $sub(A)$. sc is aligned with the distributed matrix A , and replicated down every process row. sc is tied to the distributed matrix A .

scond (global)
 REAL for single precision flavors;
 DOUBLE PRECISION for double precision flavors.
 If $info = 0$, *scond* contains the ratio of the smallest $sr(i)$ (or $sc(j)$) to the largest $sr(i)$ (or $sc(j)$), with
 $ia \leq i \leq ia+n-1$ and $ja \leq j \leq ja+n-1$.
 If $scond \geq 0.1$ and *amax* is neither too large nor too small, it is not worth scaling by sr (or sc).

amax (global)
 REAL for single precision flavors;
 DOUBLE PRECISION for double precision flavors.
 Absolute value of the largest matrix element. If *amax* is very close to overflow or very close to underflow, the matrix should be scaled.

info (global) INTEGER.
 If $info=0$, the execution is successful.
 $info < 0$:
 If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.
 $info > 0$:
 If $info = k$, the k -th diagonal entry of $sub(A)$ is nonpositive.

Orthogonal Factorizations

This section describes the ScaLAPACK routines for the QR (RQ) and LQ (QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included. For the mathematical definition of the factorizations, see the respective LAPACK sections or refer to [SLUG].

Table 6-3 lists ScaLAPACK routines that perform orthogonal factorization of matrices.

[p?geqrf](#)

Computes the QR factorization of a general m -by- n matrix.

Syntax

```
call psgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = Q^* R$$

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; ($n \geq 0$).
<i>a</i>	(local) REAL for psgeqrf DOUBLE PRECISION for pdgeqrf COMPLEX for pcgeqrf DOUBLE COMPLEX for pzgeqrf. Pointer into the local memory to an array of local dimension ($lld\_a, LOCC(ja+n-1)$). Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>
<i>work</i>	(local). REAL for psgeqrf DOUBLE PRECISION for pdgeqrf. COMPLEX for pcgeqrf. DOUBLE COMPLEX for pzgeqrf Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb\_a * (mp0+nq0+nb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$,

`iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),`
`mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),`
`nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL),`
 and `numroc, indxg2p` are ScaLAPACK tool functions; `MYROW,`
`MYCOL, NPROW` and `NPCOL` can be determined by calling the
 subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	The elements on and above the diagonal of <code>sub(A)</code> contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) REAL for <code>psgeqrf</code> DOUBLE PRECISION for <code>pdgeqrf</code> COMPLEX for <code>pcgeqrf</code> DOUBLE COMPLEX for <code>pzgeqrf</code> . Array, DIMENSION <code>LOCc(ja+min(m,n)-1)</code> . Contains the scalar factor <code>tau</code> of elementary reflectors. <code>tau</code> is tied to the distributed matrix <code>A</code> .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(j) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

p?geqpf

Computes the QR factorization of a general m-by-n matrix with pivoting.

Syntax

```
call psgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pdgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pcgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
call pzgeqpf( m, n, a, ia, ja, desca, ipiv, tau, work, lwork, info)
```

Description

The routine forms the QR factorization with column pivoting of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$\text{sub}(A) * P = Q * R$$

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for psgeqpf

DOUBLE PRECISION for pdgeqpf
 COMPLEX for pcgeqpf
 DOUBLE COMPLEX for pzgeqpf.
 Pointer into the local memory to an array of local dimension
 (*lld_a*, *LOCc(ja+n-1)*).
 Contains the local pieces of the distributed matrix sub(*A*)
 to be factored.

ia, ja (global) INTEGER. The row and column indices in the global
 array *a* indicating the first row and the first column of the
 submatrix *A(ia:ia+m-1, ja:ja+n-1)*, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The
 array descriptor for the distributed matrix *A*.

work (local).
 REAL for psgeqpf
 DOUBLE PRECISION for pdgeqpf.
 COMPLEX for pcgeqpf.
 DOUBLE COMPLEX for pzgeqpf
 Workspace array of dimension *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at
 least
For real flavors:
 $lwork \geq \max(3, mp0+nq0) + LOCc(ja+n-1) + nq0.$
For complex flavors:
 $lwork \geq \max(3, mp0+nq0) .$
 Here
 $iroff = \text{mod}(ia-1, mb\_a), icoff = \text{mod}(ja-1, nb\_a),$
 $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$
 $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$
 $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$
 $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL),$
 $LOCc(ja+n-1) = \text{numroc}(ja+n-1, nb\_a,$
 $MYCOL, csrc\_a, NPCOL),$ and *numroc*, *indxg2p* are
 ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL*
 can be determined by calling the subroutine
blacs_gridinfo.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	The elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m, n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>ipiv</i>	(local) INTEGER. Array, DIMENSION $LOCc(ja+n-1)$. $ipiv(i) = k$, the local i -th column of $\text{sub}(A)*P$ was the global k -th column of $\text{sub}(A)$. <i>ipiv</i> is tied to the distributed matrix A .
<i>tau</i>	(local) REAL for psgeqpf DOUBLE PRECISION for pdgeqpf COMPLEX for pcgeqpf DOUBLE COMPLEX for pzgeqpf. Array, DIMENSION $LOCc(ja+\min(m, n)-1)$. Contains the scalar factor <i>tau</i> of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of $lwork$ required for optimum performance.
<i>info</i>	(global) INTEGER. = 0, the execution is successful. < 0, if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n),$$

Each $H(i)$ has the form

$$H = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i-1:ia+m-1, ja+i-1)$.

The matrix P is represented in $jpvt$ as follows: if $jpvt(j) = i$ then the j -th column of P is the i -th canonical unit vector.

p?orgqr

Generates the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call psorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgqr(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?geqrf.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) REAL for psorgqr

DOUBLE PRECISION for pdorgqr
 Pointer into the local memory to an array of local dimension
 (*lld_a*, *LOCc(ja+n-1)*). The *j*-th column must contain
 the vector which defines the elementary reflector $H(j)$,
 $ja \leq j \leq ja + k - 1$, as returned by [p?geqrf](#) in the *k* columns
 of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.

ia, ja (global) INTEGER. The row and column indices in the global
 array *a* indicating the first row and the first column of the
 submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The
 array descriptor for the distributed matrix *A*.

tau (local)
 REAL for psorgqr
 DOUBLE PRECISION for pdorgqr
 Array, DIMENSION *LOCc(ja+k-1)*.
 Contains the scalar factor *tau(j)* of elementary reflectors
 $H(j)$ as returned by [p?geqrf](#). *tau* is tied to the distributed
 matrix *A*.

work (local)
 REAL for psorgqr
 DOUBLE PRECISION for pdorgqr
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*.
 Must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$,
 where
 $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1,$
 $nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$,
 $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$,
 $mpa0 = \text{numroc}(m+iroffa, mb\_a, MYROW, iarow,$
 $NPROW)$,
 $nqa0 = \text{numroc}(n+icoffa, nb\_a, MYCOL, iacol,$
 $NPCOL)$;
indxg2p and *numroc* are ScaLAPACK tool functions; MYROW,
 MYCOL, NPROW and NPCOL can be determined by calling the
 subroutine *blacs_gridinfo*.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of $lwork$ required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by `p?geqrf`.

Syntax

```
call pcungqr( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungqr( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?geqrf`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix <code>sub(Q)</code> ; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix <code>sub(Q)</code> ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> ($n \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for <code>pcungqr</code> DOUBLE COMPLEX for <code>pzungqr</code> Pointer into the local memory to an array of dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). The <i>j</i> -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the <i>k</i> columns of its distributed matrix argument <code>A(ia:*, ja:ja+k-1)</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcungqr</code> DOUBLE COMPLEX for <code>pzungqr</code> Array, DIMENSION <code>LOCc(ja+k-1)</code> . Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by <code>p?geqrf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for <code>pcungqr</code> DOUBLE COMPLEX for <code>pzungqr</code> Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$,

```

icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

a	Contains the local pieces of the m -by- n distributed matrix Q .
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ormqr

Multiplies a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```

call psormqr( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdormqr( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

```

Description

The routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by `p?geqrf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER ='L': Q or Q^T is applied from the left. ='R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER ='N', no transpose, Q is applied. ='T', transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) REAL for <code>psormqr</code> DOUBLE PRECISION for <code>pdormqr</code> . Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+k-1))$. The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of

	its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.
	If $side = 'L'$, $lld\_a \geq \max(1, LOCr(ia+m-1))$
	If $side = 'R'$, $lld\_a \geq \max(1, LOCr(ia+n-1))$
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A .
tau	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Array, DIMENSION $LOCc(ja+k-1)$. Contains the scalar factor $tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqrf. tau is tied to the distributed matrix A .
c	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Pointer into the local memory to an array of local dimension $(lld\_c, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix $sub(C)$ to be factored.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix C , respectively.
$descc$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix C .
$work$	(local) REAL for psormqr DOUBLE PRECISION for pdormqr. Workspace array of dimension of $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least: if $side = 'L'$,

```

lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0+mpc0)*nb_a
+ nb_a*nb_a
else if side = 'R',
lwork ≥ max((nb_a*(nb_a-1))/2,
(nqc0+max(npa0+numroc(numroc(n+icoffc, nb_a, 0,
0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) +
nb_a*nb_a

calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pzerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q^T$, or $\text{sub}(C) \cdot Q$.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
call pcunmqr( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )

call pzunmqr( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )
```

Description

The routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$ as returned by p?geqrf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER
 = 'L': Q or Q^H is applied from the left.
 = 'R': Q or Q^H is applied from the right.

trans (global) CHARACTER
 = 'N', no transpose, Q is applied.

	= 'C', conjugate transpose, Q^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub(<i>c</i>) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub(<i>c</i>) ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja+k-1</i>)). The <i>j</i> -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja + k - 1$, as returned by p?geqrf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', $lld\_a \geq \max(1, LOCr(ia+m-1))$ If <i>side</i> = 'R', $lld\_a \geq \max(1, LOCr(ia+n-1))$
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmqr DOUBLE COMPLEX for pzunmqr Array, DIMENSION <i>LOCc</i> (<i>ja+k-1</i>). Contains the scalar factor <i>tau</i> (<i>j</i>) of elementary reflectors $H(j)$ as returned by p?geqrf . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local)

COMPLEX for pcunmqr
DOUBLE COMPLEX for pzunmqr.
Pointer into the local memory to an array of local dimension
(*lld_c*, *LOCc(jc+n-1)*).
Contains the local pieces of the distributed matrix sub(*c*)
to be factored.

ic, jc (global) INTEGER. The row and column indices in the global
array *c* indicating the first row and the first column of the
submatrix *c*, respectively.

desc (global and local) INTEGER array, dimension (*dlen_*). The
array descriptor for the distributed matrix *c*.

work (local)
COMPLEX for pcunmqr
DOUBLE COMPLEX for pzunmqr.
Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at
least:
If *side* = 'L',
 $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$
else if *side* = 'R',
 $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + ioffset, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a$
end if
where
 $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(ia - 1, mb\_a)$,
 $icoffa = \text{mod}(ja - 1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$,
 $npa0 = \text{numroc}(n + iroffa, mb\_a, MYROW, iarow, NPROW)$,
 $iroffc = \text{mod}(ic - 1, mb\_c)$,
 $icoffc = \text{mod}(jc - 1, nb\_c)$,
 $icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW)$,
 $iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL)$,

```

mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxcg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p?erbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q^H \text{sub}(C)$, or $\text{sub}(C) * Q^H$, or $\text{sub}(C) * Q$.
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?gelqf

Computes the LQ factorization of a general rectangular matrix.

Syntax

```

call psgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelqf( m, n, a, ia, ja, desca, tau, work, lwork, info)

```

Description

The routine computes the LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ia}:\text{ia}+n-1) = L^*Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Pointer into the local memory to an array of local dimension $(\text{lld\_a}, \text{LOCc}(\text{ja}+n-1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A((\text{ia}:\text{ia}+m-1, \text{ia}:\text{ia}+n-1))$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (dlen_) . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $\text{lwork} \geq \text{mb\_a} * (\text{mp0} + \text{nq0} + \text{mb\_a})$, where $\text{iroff} = \text{mod}(\text{ia}-1, \text{mb\_a})$,

```
icoff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	The elements on and below the diagonal of sub(<i>A</i>) contain the <i>m</i> by min(<i>m</i> , <i>n</i>) lower trapezoidal matrix <i>L</i> (<i>L</i> is lower trapezoidal if <i>m</i> ≤ <i>n</i>); the elements above the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) REAL for psgelqf DOUBLE PRECISION for pdgelqf COMPLEX for pcgelqf DOUBLE COMPLEX for pzgelqf Array, DIMENSION <i>LOCr</i> (<i>ia</i> +min(<i>m</i> , <i>n</i>)-1)). Contains the scalar factors of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i-1:ia+i-1, ja+n-1)$, and τ in $\tau(ia+i-1)$.

p?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call psorglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?gelqf.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq m \geq 0$).

<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i>	(local) REAL for psorglq DOUBLE PRECISION for pdorglq Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja+n-1</i>)). On entry, the <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A((ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psorglq DOUBLE PRECISION for pdorglq Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$, $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW)$, $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .

Output Parameters

<i>a</i>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<i>tau</i>	(local) REAL for psorglq DOUBLE PRECISION for pdorglq Array, DIMENSION $LOCr(ia+k-1)$. Contains the scalar factors <i>tau</i> of elementary reflectors $H(i)$. <i>tau</i> is tied to the distributed matrix A .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unglq

Generates the unitary matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call pcunglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzunglq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by p?gelqf.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix <code>sub(Q)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix <code>sub(Q)</code> ($n \geq m \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> ($m \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Pointer into the local memory to an array of local dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, the <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the <i>k</i> rows of its distributed matrix argument <code>A(ia:ia+k-1, ja:*)</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <code>A(ia:ia+m-1, ja:ja+n-1)</code> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Array, DIMENSION <code>LOCr(ia+k-1)</code> . Contains the scalar factors <i>tau</i> of elementary reflectors $H(i)$. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for <code>pcunglq</code> DOUBLE COMPLEX for <code>pzunglq</code> Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$,

```

iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL)

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ormlq

Multiplies a general matrix by the orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```

call psormlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work,
lwork, info)

call pdormlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, work,
lwork, info)

```

Description

The routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by `p?gelqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
a	(local) REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code> . Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+m-1))$, if $side = 'L'$ and $(lld\_a, LOCC(ja+n-1))$, if $side = 'R'$. The i -th row must contain

	the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code> Array, DIMENSION $LOCc(ja+k-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by <code>p?gelqf</code>. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code> Pointer into the local memory to an array of local dimension ($lld\_c, LOCc(jc+n-1)$). Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for <code>psormlq</code> DOUBLE PRECISION for <code>pdormlq</code>. Workspace array of dimension of <i>lwork</i>.
<i>lwork</i>	(local or global) INTEGER, dimension of the array <i>work</i>; must be at least: If <i>side</i> = 'L',

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0+max mqa0)+
numroc(numroc(m + iroffc, mb_a, 0, 0, NPROW),
mb_a, 0, 0, lcmp), nqc0))* mb_a) + mb_a*mb_a
else if side = 'R',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0+nqc0)*mb_a
+ mb_a*mb_a
end if
where
lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol,
NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(c)$, or $Q' \cdot \text{sub}(c)$, or $\text{sub}(c) \cdot Q'$, or $\text{sub}(c) \cdot Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER.

= 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmlq

Multiplies a general matrix by the unitary matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
call pcunmlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )

call pzunmlq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info )
```

Description

The routine overwrites the general complex m -by- n distributed matrix $sub(C) = C$ ($ic:ic+m-1, jc:jc+n-1$) with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by p?gelqf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER
 = 'L': Q or Q^H is applied from the left.
 = 'R': Q or Q^H is applied from the right.

trans (global) CHARACTER
 = 'N', no transpose, Q is applied.
 = 'C', conjugate transpose, Q^H is applied.

<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for pcunmlq DOUBLE COMPLEX for pzunmlq. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+m-1)</i>), if <i>side</i> = 'L', and (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>), if <i>side</i> = 'R', where $lld\_a \geq \max(1, LOCr(ia+k-1))$. The <i>i</i> -th column must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmlq DOUBLE COMPLEX for pzunmlq Array, DIMENSION <i>LOCc(ia+k-1)</i> . Contains the scalar factor <i>tau(i)</i> of elementary reflectors $H(i)$ as returned by <code>p?gelqf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmlq DOUBLE COMPLEX for pzunmlq.

	Pointer into the local memory to an array of local dimension $(lld\_c, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix sub(c) to be factored.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix c, respectively.
$descc$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix c.
$work$	(local) COMPLEX for pcunmlq DOUBLE COMPLEX for pzunmlq. Workspace array of dimension of $lwork$.
$lwork$	(local or global) INTEGER, dimension of the array $work$; must be at least: If $side = 'L'$, $lwork \geq \max((mb\_a*(mb\_a-1))/2, (mpc0 + \max mqa0) +$ $\text{numroc}(\text{numroc}(m + iroffc, mb\_a, 0, 0, NPROW),$ $mb\_a, 0, 0, lcm), nqc0))*mb\_a) + mb\_a*mb\_a$ else if $side = 'R'$, $lwork \geq \max((mb\_a*(mb\_a-1))/2, (mpc0 +$ $nqc0)*mb\_a + mb\_a*mb\_a$ end if where $lcm = lcm/NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mqa0 = \text{numroc}(m + icoffa, nb\_a, MYCOL, iacol,$ $NPCOL),$ $iroffc = \text{mod}(ic-1, mb\_c),$ $icoffc = \text{mod}(jc-1, nb\_c),$ $icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW),$ $iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL),$ $mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow,$ $NPROW),$

`nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),`
`ilcm, indxg2p` and `numroc` are ScaLAPACK tool functions;
`MYROW, MYCOL, NPROW` and `NPCOL` can be determined by
calling the subroutine `blacs_gridinfo`.
If `lwork = -1`, then `lwork` is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(c)$, or $Q' \cdot \text{sub}(c)$, or $\text{sub}(c) \cdot Q'$, or $\text{sub}(c) \cdot Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?geqlf

Computes the QL factorization of a general matrix.

Syntax

```
call psgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqlf(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine forms the QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*L$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq 0$).
<i>a</i>	(local) REAL for psgeqlf DOUBLE PRECISION for pdgeqlf COMPLEX for pcgeqlf DOUBLE COMPLEX for pzgeqlf Pointer into the local memory to an array of local dimension $(lld\_a, LOCC(ja+n-1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A((ia:ia+m-1, ja:ja+n-1))$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgeqlf DOUBLE PRECISION for pdgeqlf COMPLEX for pcgeqlf DOUBLE COMPLEX for pzgeqlf Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb\_a * (mp0 + nq0 + nb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a),$ $icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$

`nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL)`
`numroc` and `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) REAL for psgeqlf DOUBLE PRECISION for pdgeqlf COMPLEX for pcgeqlf DOUBLE COMPLEX for pzgeqlf Array, DIMENSION <code>LOCc(ja+n-1)</code> . Contains the scalar factors of elementary reflectors. <code>tau</code> is tied to the distributed matrix A .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = $-(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(m-k+i-1)$ is stored on exit in $A(ia+ia+m-k+i-2, ja+n-k+i-1)$, and τ in $\tau(ja+n-k+i-1)$.

p?orgql

Generates the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
call psorgql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?geqlf.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).

<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) REAL for psorgql DOUBLE PRECISION for pdorgql Pointer into the local memory to an array of local dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja+n-1</i>)). On entry, the <i>j</i> -th column must contain the vector which defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument $A(ia:ja+n-k:ja+n-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A((ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psorgql DOUBLE PRECISION for pdorgql Array, DIMENSION <i>LOCc</i> (<i>ja+n-1</i>). Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psorgql DOUBLE PRECISION for pdorgql Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info</code> = $-(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?ungql

Generates the unitary matrix Q of the Q^L factorization formed by `p?geqlf`.

Syntax

```
call pcungql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungql( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first n columns of a product of k elementary reflectors of order m

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by `p?geqlf`.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
<i>a</i>	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Pointer into the local memory to an array of local dimension (lld_a , $LOCc(ja+n-1)$). On entry, the j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(ia:*, ja+n-k: ja+n-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension ($dlen\_$). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Array, DIMENSION $LOCr(ia+n-1)$. Contains the scalar factors $\tau(j)$ of elementary reflectors $H(j)$. τ is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) COMPLEX for pcungql DOUBLE COMPLEX for pzungql Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$,

```

iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

a	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
$work(1)$	On exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p_?ormql

Multiplies a general matrix by the orthogonal matrix Q of the QL factorization formed by p_?geqlf.

Syntax

```

call psormql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdormql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

```

Description

The routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C$ ($ic:ic+m-1, jc:jc+n-1$) with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) REAL for <code>psormql</code> DOUBLE PRECISION for <code>pdormql</code> . Pointer into the local memory to an array of dimension ($lld\_a, LOCC(ja+k-1)$). The j -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?gelqf</code> in the k columns of

	its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit.
	If $side = 'L'$, $lld\_a \geq \max(1, LOCr(ia+m-1))$,
	If $side = 'R'$, $lld\_a \geq \max(1, LOCr(ia+n-1))$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A .
tau	(local) REAL for psormql DOUBLE PRECISION for pdormql. Array, DIMENSION $LOCc(ja+n-1)$). Contains the scalar factor $tau(j)$ of elementary reflectors $H(j)$ as returned by p?geqlf. tau is tied to the distributed matrix A .
c	(local) REAL for psormql DOUBLE PRECISION for pdormql. Pointer into the local memory to an array of local dimension $(lld\_c, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix sub(c) to be factored.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix C , respectively.
$descc$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix C .
$work$	(local) REAL for psormql DOUBLE PRECISION for pdormql. Workspace array of dimension of $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least: If $side = 'L'$,

```

lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0+mpc0)*nb_a
+ nb_a*nb_a
else if side = 'R',
lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0+max npa0)+
numroc(numroc(n+icoffc, nb_a, 0, 0, NPCOL),
nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
end if
where
lcmp = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(n + iroffa, mb_a, MYROW, iarow,
NPROW),

iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pserbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q^* \text{sub}(c)$, or $Q^* \text{sub}(c)$, or $\text{sub}(c)^* Q'$, or $\text{sub}(c)^* Q$
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER.

= 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmql

Multiplies a general matrix by the unitary matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
call pcunmql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunmql( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C$ ($ic:ic+m-1, jc:jc+n-1$) with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'C':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by p?geqlf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER
 = 'L': Q or Q^H is applied from the left.
 = 'R': Q or Q^H is applied from the right.

trans (global) CHARACTER
 = 'N', no transpose, Q is applied.
 = 'C', conjugate transpose, Q^H is applied.

<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) COMPLEX for <code>pcunmql</code> DOUBLE COMPLEX for <code>pzunmql</code> . Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+k-1)</i>). The <i>j</i> -th column must contain the vector which defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqlf</code> in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', $lld\_a \geq \max(1, LOCr(ia+m-1))$, If <i>side</i> = 'R', $lld\_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunmql</code> DOUBLE COMPLEX for <code>pzunmql</code> Array, DIMENSION <i>LOCc(ia+n-1)</i> . Contains the scalar factor <i>tau(j)</i> of elementary reflectors $H(j)$ as returned by <code>p?geqlf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for <code>pcunmql</code>

DOUBLE COMPLEX for pzunmql.
 Pointer into the local memory to an array of local dimension
 (*lld_c*, *LOCc(jc+n-1)*).
 Contains the local pieces of the distributed matrix sub(*c*)
 to be factored.

ic, jc (global) INTEGER. The row and column indices in the global
 array *c* indicating the first row and the first column of the
 submatrix *c*, respectively.

descc (global and local) INTEGER array, dimension (*dlen_*). The
 array descriptor for the distributed matrix *c*.

work (local)
 COMPLEX for pcunmql
 DOUBLE COMPLEX for pzunmql.
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at
 least:
 If *side* = 'L',

$$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a + nb\_a * nb\_a)$$
 else if *side* = 'R',

$$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max npa0) + \text{numroc}(\text{numroc}(n + iroffa, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a + nb\_a * nb\_a)$$
 end if
 where

$$lcmp = lcm / NPCOL \text{ with } lcm = ilcm(NPROW, NPCOL),$$

$$iroffa = \text{mod}(ia - 1, mb\_a),$$

$$icoffa = \text{mod}(ja - 1, nb\_a),$$

$$iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$$

$$npa0 = \text{numroc}(n + iroffa, mb\_a, MYROW, iarow, NPROW),$$

$$iroffc = \text{mod}(ic - 1, mb\_c),$$

$$icoffc = \text{mod}(jc - 1, nb\_c),$$

$$icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW),$$

$$iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL),$$

$$mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow, NPROW),$$

`nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),`
`ilcm, indxcg2p` and `numroc` are ScaLAPACK tool functions;
`MYROW, MYCOL, NPROW` and `NPCOL` can be determined by
calling the subroutine `blacs_gridinfo`.
If `lwork = -1`, then `lwork` is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pserbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(c)$, or $Q' \text{sub}(c)$, or $\text{sub}(c)^* Q$, or $\text{sub}(c)^* Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?gerqf

Computes the RQ factorization of a general rectangular matrix.

Syntax

```
call psgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerqf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = R^*Q$$

Input Parameters

m	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(A)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed submatrix $\text{sub}(A)$; ($n \geq 0$).
a	(local) REAL for <code>psgeqrf</code> DOUBLE PRECISION for <code>pdgeqrf</code> COMPLEX for <code>pcgeqrf</code> DOUBLE COMPLEX for <code>pzgeqrf</code> . Pointer into the local memory to an array of local dimension $(lld\_a, LOCC(ja+n-1))$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A
$work$	(local). REAL for <code>psgeqrf</code> DOUBLE PRECISION for <code>pdgeqrf</code> . COMPLEX for <code>pcgeqrf</code> . DOUBLE COMPLEX for <code>pzgeqrf</code> Workspace array of dimension $lwork$.
$lwork$	(local or global) INTEGER, dimension of $work$, must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$,

`iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),`
`iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),`
`mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),`
`nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL)`
and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

`a`

On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array `tau`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

`tau`

(local)
 REAL for `psgeqrf`
 DOUBLE PRECISION for `pdgeqrf`
 COMPLEX for `pcgeqrf`
 DOUBLE COMPLEX for `pzgeqrf`.
 Array, DIMENSION `LOCr(ia+m-1)`.
 Contains the scalar factor `tau` of elementary reflectors. `tau` is tied to the distributed matrix A .

`work(1)`

On exit, `work(1)` contains the minimum value of `lwork` required for optimum performance.

`info`

(global) INTEGER.
 = 0, the execution is successful.

< 0 , if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)/\text{conjg}(v(1:n-k+i-1))$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $\tau(ia+m-k+i-1)$.

p?orgrq

Generates the orthogonal matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call psorgrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last m rows of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?gerqf.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows in the submatrix <code>sub(Q)</code> ; ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the submatrix <code>sub(Q)</code> ($n \geq m \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> ($m \geq k \geq 0$).
<i>a</i>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Pointer into the local memory to an array of local dimension (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). The <i>i</i> -th column must contain the vector which defines the elementary reflector $H(i)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?gerqf</code> in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Array, DIMENSION <code>LOCc(ja+k-1)</code> . Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by <code>p?gerqf</code> . <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <code>psorgqr</code> DOUBLE PRECISION for <code>pdorgqr</code> Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$,

```

icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL)
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?ungrq

Generates the unitary matrix *Q* of the *RQ* factorization formed by [p?gerqf](#).

Syntax

```

call pcungrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungrq( m, n, k, a, ia, ja, desca, tau, work, lwork, info)

```

Description

The routine generates the m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$$Q = (H(1))^H \star (H(2))^H \star \dots \star (H(k))^H \text{ as returned by } \text{p?gerqf}.$$

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(Q)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(Q)$ ($n \geq m \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrqc Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+n-1))$. The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by p?gerqf in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A .
τ	(local) COMPLEX for pcungrq DOUBLE COMPLEX for pzungrqc Array, DIMENSION $LOCr(ia+m-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?gerqf . τ is tied to the distributed matrix A .

work (local)
 COMPLEX for pcungrq
 DOUBLE COMPLEX for pzungrq
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER, dimension of *work*, must be at least $lwork \geq mb\_a*(mpa0 + nqa0 + mb\_a)$, where

```

iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)

```

indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a Contains the local pieces of the m -by- n distributed matrix Q .

work(1) On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?ormrq

Multiplies a general matrix by the orthogonal matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call psormrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine overwrites the general real m -by- n distributed matrix $\text{sub}(C)$ = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by p?gerqf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
$trans$	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).

<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr. Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>m</i>-1)) if <i>side</i> = 'L', and (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)) if <i>side</i> = 'R'. The <i>i</i>-th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) REAL for psormqr DOUBLE PRECISION for pdormqr Array, DIMENSION <i>LOCc</i>(<i>ja</i>+<i>k</i>-1)). Contains the scalar factor <i>tau</i>(<i>i</i>) of elementary reflectors $H(i)$ as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) REAL for psormrq DOUBLE PRECISION for pdormrq Pointer into the local memory to an array of local dimension (<i>lld_c</i>, <i>LOCc</i>(<i>jc</i>+<i>n</i>-1)). Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.

<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) REAL for psormrq DOUBLE PRECISION for pdormrq. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a) + mb\_a * mb\_a$ end if where <i>lcmp</i> = <i>lcm</i> / <i>NPROW</i> with <i>lcm</i> = <i>ilcm</i> (<i>NPROW</i> , <i>NPCOL</i>), <i>iroffa</i> = <i>mod</i> (<i>ia</i> - 1, <i>mb_a</i>), <i>icoffa</i> = <i>mod</i> (<i>ja</i> - 1, <i>nb_a</i>), <i>iacol</i> = <i>indxg2p</i> (<i>ja</i> , <i>nb_a</i> , <i>MYCOL</i> , <i>csrc_a</i> , <i>NPCOL</i>), <i>mqa0</i> = <i>numroc</i> (<i>n</i> + <i>icoffa</i> , <i>nb_a</i> , <i>MYCOL</i> , <i>iacol</i> , <i>NPCOL</i>), <i>iroffc</i> = <i>mod</i> (<i>ic</i> - 1, <i>mb_c</i>), <i>icoffc</i> = <i>mod</i> (<i>jc</i> - 1, <i>nb_c</i>), <i>icrow</i> = <i>indxg2p</i> (<i>ic</i> , <i>mb_c</i> , <i>MYROW</i> , <i>rsrc_c</i> , <i>NPROW</i>), <i>iccol</i> = <i>indxg2p</i> (<i>jc</i> , <i>nb_c</i> , <i>MYCOL</i> , <i>csrc_c</i> , <i>NPCOL</i>), <i>mpc0</i> = <i>numroc</i> (<i>m</i> + <i>iroffc</i> , <i>mb_c</i> , <i>MYROW</i> , <i>icrow</i> , <i>NPROW</i>), <i>nqc0</i> = <i>numroc</i> (<i>n</i> + <i>icoffc</i> , <i>nb_c</i> , <i>MYCOL</i> , <i>iccol</i> , <i>NPCOL</i>), <i>ilcm</i> , <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>MYROW</i> , <i>MYCOL</i> , <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c	Overwritten by the product $Q^* \text{sub}(c)$, or $Q'^* \text{sub}(c)$, or $\text{sub}(c)^* Q'$, or $\text{sub}(c)^* Q$
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmrq

Multiplies a general matrix by the unitary matrix Q of the RQ factorization formed by p?gerqf.

Syntax

```
call pcunmrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmrq( side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine overwrites the general complex m -by- n distributed matrix $\text{sub}(c) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q^* \text{sub}(c)$	$\text{sub}(c)^* Q$
$trans = 'C':$	$Q^H \text{sub}(c)$	$\text{sub}(c)^* Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `p?gerqf`. Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

<code>side</code>	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
<code>trans</code>	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
<code>m</code>	(global) INTEGER. The number of rows in the distributed matrix sub(C) ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns in the distributed matrix sub(C) ($n \geq 0$).
<code>k</code>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <code>side = 'L'</code> , $m \geq k \geq 0$ If <code>side = 'R'</code> , $n \geq k \geq 0$.
<code>a</code>	(local) COMPLEX for <code>pcunmrq</code> DOUBLE COMPLEX for <code>pzunmrq</code> . Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+m-1))$ if <code>side = 'L'</code> , and $(lld\_a, LOCC(ja+n-1))$ if <code>side = 'R'</code> . The i -th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja^*)$. $A(ia:ia+k-1, ja^*)$ is modified by the routine but restored on exit.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array <code>a</code> indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq Array, DIMENSION <i>LOCc(ja+k-1)</i> . Contains the scalar factor <i>tau(i)</i> of elementary reflectors <i>H(i)</i> as returned by p?gerqf. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq. Pointer into the local memory to an array of local dimension (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) COMPLEX for pcunmrq DOUBLE COMPLEX for pzunmrq. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a*(mb\_a-1))/2, (mpc0 + \max(mqa0+numroc(numroc(n+iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0))*mb\_a) + mb\_a*mb\_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb\_a*(mb\_a-1))/2, (mpc0 + nqc0)*mb\_a) + mb\_a*mb\_a$ end if

where

```
lcmp = lcm/NPROW with lcm = ilcm(NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol,
NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
```

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(c)$ or $Q'^* \text{sub}(c)$, or $\text{sub}(c)^* Q'$, or $\text{sub}(c)^* Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?tzzrf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax

```
call pstzzrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdtzzrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pctzzrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
call pztzzrf( m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

This routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = (ia:ia+m-1, ja:ja+n-1)$ to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m	(global) INTEGER. The number of rows in the submatrix $\text{sub}(A)$; ($m \geq 0$).
n	(global) INTEGER. The number of columns in the submatrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for pstzzrf DOUBLE PRECISION for pdtzzrf. COMPLEX for pctzzrf. DOUBLE COMPLEX for pztzzrf. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+n-1))$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <i>pstzrzf</i> DOUBLE PRECISION for <i>pdtzrzf</i> . COMPLEX for <i>pctzrzf</i> . DOUBLE COMPLEX for <i>pztzrzf</i> . Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$, $mp0 = \text{numroc}(m + iroff, mb\_a, MYROW, iarow, NPROW)$, $nq0 = \text{numroc}(n + icoff, nb\_a, MYCOL, iacol, NPCOL)$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	On exit, the leading <i>m</i> -by- <i>m</i> upper triangular part of sub(<i>A</i>) contains the upper triangular matrix <i>R</i> , and elements <i>m</i> +1 to <i>n</i> of the first <i>m</i> rows of sub (<i>A</i>), with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Z</i> as a product of <i>m</i> elementary reflectors.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>tau</i>	(local)

REAL for pstzrzf
 DOUBLE PRECISION for pdtzrzf.
 COMPLEX for pctzrzf.
 DOUBLE COMPLEX for pztzrzf.
 Array, DIMENSION $LOCr(ia+m-1)$.
 Contains the scalar factor of elementary reflectors. τ is tied to the distributed matrix A .
info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The factorization is obtained by the Householder's method. The k -th transformation matrix, $Z(k)$, which is or whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ -th row of $\text{sub}(A)$, is given in the form

$$Z(k) = \begin{bmatrix} i & 0 \\ 0 & T(k) \end{bmatrix}$$

where

$$T(k) = i - \tau u(k) u(k)^*,$$

$$u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $Z(k)$ is an $(n - m)$ element vector. τ and $Z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $Z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$. Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

p?ormrz

Multiplies a general matrix by the orthogonal matrix from a reduction to upper triangular form formed by p?tzzrf.

Syntax

```
call psormrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdormrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by p?tzzrf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
$trans$	(global) CHARACTER = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>l</i>	(global) The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$ If <i>side</i> = 'R', $n \geq l \geq 0$.
<i>a</i>	(local) REAL for psormrz DOUBLE PRECISION for pdormrz. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>m</i> -1)) if <i>side</i> = 'L', and (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)) if <i>side</i> = 'R', where <i>lld_a</i> $\geq \max(1, \text{LOCr}(\text{ia}+k-1))$. The <i>i</i> -th row must contain the vector which defines the elementary reflector $H(i)$, $\text{ia} \leq i \leq \text{ia}+k-1$, as returned by p?tzrpf in the <i>k</i> rows of its distributed matrix argument $A(\text{ia}:\text{ia}+k-1, \text{ja}:*)$. $A(\text{ia}:\text{ia}+k-1, \text{ja}:*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormrz DOUBLE PRECISION for pdormrz Array, DIMENSION <i>LOCc</i> (<i>ia</i> + <i>k</i> -1). Contains the scalar factor <i>tau</i> (<i>i</i>) of elementary reflectors $H(i)$ as returned by p?tzrpf. <i>tau</i> is tied to the distributed matrix <i>A</i> .

<i>c</i>	(local) REAL for psormrz DOUBLE PRECISION for pdormrz Pointer into the local memory to an array of local dimension (<i>lld_c</i>, <i>LOCc(jc+n-1)</i>). Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i>, respectively.
<i>desc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i>.
<i>work</i>	(local) REAL for psormrz DOUBLE PRECISION for pdormrz. Workspace array of dimension of <i>lwork</i>.
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i>, must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffa, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a) + mb\_a * mb\_a$ end if where <i>lcmp</i> = <i>lcm</i> / NPROW with <i>lcm</i> = <i>ilcm</i> (NPROW, NPCOL), <i>iroffa</i> = mod(<i>ia</i>-1, <i>mb_a</i>), <i>icoffa</i> = mod(<i>ja</i>-1, <i>nb_a</i>), <i>iacol</i> = indxg2p(<i>ja</i>, <i>nb_a</i>, MYCOL, <i>csrc_a</i>, NPCOL), <i>mqa0</i> = numroc(<i>n</i>+<i>icoffa</i>, <i>nb_a</i>, MYCOL, <i>iacol</i>, NPCOL), <i>iroffc</i> = mod(<i>ic</i>-1, <i>mb_c</i>), <i>icoffc</i> = mod(<i>jc</i>-1, <i>nb_c</i>), <i>icrow</i> = indxg2p(<i>ic</i>, <i>mb_c</i>, MYROW, <i>rsrc_c</i>, NPROW), <i>iccol</i> = indxg2p(<i>jc</i>, <i>nb_c</i>, MYCOL, <i>csrc_c</i>, NPCOL),

```

mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by p?xerbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q*\text{sub}(c)$, or $Q'*\text{sub}(c)$, or $\text{sub}(c)*Q'$, or $\text{sub}(c)*Q$
<i>work(1)</i>	On exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?unmrz

Multiplies a general matrix by the unitary transformation matrix from a reduction to upper triangular form determined by p?tzrzf.

Syntax

```

call pcunmrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunmrz( side, trans, m, n, k, l, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

```

Description

The routine overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'C':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `pctzrzf/pztzrzf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied.
m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(C)$, ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(C)$, ($n \geq 0$).
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
l	(global) INTEGER. The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If $side = 'L'$, $m \geq l \geq 0$ If $side = 'R'$, $n \geq l \geq 0$.
a	(local)

	COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Pointer into the local memory to an array of dimension $(lld\_a, LOCc(ja+m-1))$ if $side = 'L'$, and $(lld\_a, LOCc(ja+n-1))$ if $side = 'R'$, where $lld\_a \geq \max(1, LOCr(ja+k-1))$. The i-th row must contain the vector which defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja^*)$. $A(ia:ia+k-1, ja^*)$ is modified by the routine but restored on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz Array, DIMENSION $LOCc(ia+k-1)$. Contains the scalar factor $\tau(i)$ of elementary reflectors $H(i)$ as returned by p?gerqf. τ is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) COMPLEX for pcunmrz DOUBLE COMPLEX for pzunmrz. Pointer into the local memory to an array of local dimension $(lld\_c, LOCc(jc+n-1))$. Contains the local pieces of the distributed matrix sub(<i>c</i>) to be factored.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) COMPLEX for pcunmrz

lwork

DOUBLE COMPLEX for pzunmrz.
 Workspace array of dimension *lwork*.
 (local or global) INTEGER, dimension of *work*, must be at least:
 If *side* = 'L',

$$lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffa, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a)$$

 else if *side* = 'R',

$$lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a + mb\_a * mb\_a)$$

 end if
 where

$$lcmp = lcm / NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$$

$$iroffa = \text{mod}(ia - 1, mb\_a),$$

$$icoffa = \text{mod}(ja - 1, nb\_a),$$

$$iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$$

$$mqa0 = \text{numroc}(m + icoffa, nb\_a, MYCOL, iacol, NPCOL),$$

$$iroffc = \text{mod}(ic - 1, mb\_c),$$

$$icoffc = \text{mod}(jc - 1, nb\_c),$$

$$icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW),$$

$$iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL),$$

$$mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow, NPROW),$$

$$nqc0 = \text{numroc}(n + icoffc, nb\_c, MYCOL, iccol, NPCOL),$$

$$ilcm, \text{indxg2p} \text{ and } \text{numroc} \text{ are ScaLAPACK tool functions;}$$

$$MYROW, MYCOL, NPROW \text{ and } NPCOL \text{ can be determined by}$$

 calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(c)$, or $Q'^* \text{sub}(c)$, or $\text{sub}(c) * Q'$, or $\text{sub}(c) * Q$
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info</code> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = - <i>i</i> .

p?ggqrf

Computes the generalized QR factorization.

Syntax

```
call psggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)

call pdggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)

call pcggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)

call pzggqrf(n, m, p, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)
```

Description

The routine forms the generalized QR factorization of an n -by- m matrix

$\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)$

and an n -by- p matrix

$\text{sub}(B) = B(ib:ib+n-1, jb:jb+p-1):$

as

$\text{sub}(A) = Q^* R, \text{sub}(B) = Q^* T^* Z,$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

If $n \geq m$

$$R = \begin{pmatrix} R_{11} & \\ & 0 \end{pmatrix} \begin{matrix} m \\ n - m \\ m \end{matrix}$$

or if $n < m$

$$R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} n \\ n \\ m - n \end{matrix}$$

where R_{11} is upper triangular, and

$$T = \begin{pmatrix} 0 & T_{12} \\ & \end{pmatrix} \begin{matrix} n, \text{ if } n \leq p, \\ p - n & n \end{matrix}$$

$$T = \begin{pmatrix} 0 & T_{12} \\ & \end{pmatrix} \begin{matrix} n, \text{ if } n \leq p, \\ p - n & n \end{matrix}$$

$$\text{or } T = \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \begin{pmatrix} n - p \\ p \end{pmatrix}, \text{ if } n > p,$$

p

where T_{12} or T_{21} is an upper triangular matrix.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GQR factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the QR factorization of $\text{inv}(\text{sub}(B)) * \text{sub}(A)$:

$$\text{inv}(\text{sub}(B)) * \text{sub}(A) = Z^H * (\text{inv}(T) * R$$

Input Parameters

n	(global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
m	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
p	INTEGER. The number of columns in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
a	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+m-1))$. Contains the local pieces of the n -by- m matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A .
b	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Pointer into the local memory to an array of dimension $(lld\_b, LOCC(jb+p-1))$. Contains the local pieces of the n -by- p matrix $\text{sub}(B)$ to be factored.
ib, jb	(global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix B.

work (local)
 REAL for psggqrf
 DOUBLE PRECISION for pdggqrf
 COMPLEX for pcggqrf
 DOUBLE COMPLEX for pzggqrf.
 Workspace array of dimension of *lwork*.

lwork (local or global) INTEGER. Dimension of *work*, must be at least

$$lwork \geq \max(nb\_a * (npa0 + mqa0 + nb\_a), \\ \max((nb\_a * (nb\_a - 1)) / 2, \\ (pqb0 + npb0) * nb\_a + nb\_a * nb\_a, \\ mb\_b * (npb0 + pqb0 + mb\_b)),$$

where

$$iroffa = \text{mod}(ia - 1, mb\_a), \\ icoffa = \text{mod}(ja - 1, nb\_a), \\ iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW), \\ iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL), \\ npa0 = \text{numroc}(n + iroffa, mb\_a, MYROW, iarow, NPROW), \\ mqa0 = \text{numroc}(m + icoffa, nb\_a, MYCOL, iacol, NPCOL) \\ iroffb = \text{mod}(ib - 1, mb\_b), \\ icoffb = \text{mod}(jb - 1, nb\_b), \\ ibrow = \text{indxg2p}(ib, mb\_b, MYROW, rsrc\_b, NPROW), \\ ibcol = \text{indxg2p}(jb, nb\_b, MYCOL, csrc\_b, NPCOL), \\ npb0 = \text{numroc}(n + iroffb, mb\_b, MYROW, ibrow, NPROW), \\ pqb0 = \text{numroc}(m + icoffb, nb\_b, MYCOL, ibcol, NPCOL)$$

and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the elements on and above the diagonal of sub (<i>A</i>) contain the $\min(n, m)$ -by- m upper trapezoidal matrix R (R is upper triangular if $n \geq m$); the elements below the diagonal, with the array <i>taua</i> , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors. (See Application Notes below).
<i>taua, taub</i>	(local) REAL for psggqrf DOUBLE PRECISION for pdggqrf COMPLEX for pcggqrf DOUBLE COMPLEX for pzggqrf. Arrays, DIMENSION $LOCc(ja+\min(n, m)-1)$ for <i>taua</i> and $LOCr(ib+n-1)$ for <i>taub</i>. The array <i>taua</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q. <i>taua</i> is tied to the distributed matrix <i>A</i>. (See Application Notes below). The array <i>taub</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z. <i>taub</i> is tied to the distributed matrix <i>B</i>. (See Application Notes below).
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of $lwork$ required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then $info = -(i*100+j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1),$$

where $k = \min(n, m)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_{aua} * v * v'$$

where τ_{aua} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i:ia+n-1, ja+i-1)$, and τ_{aua} in $\tau_{aua}(ja+i-1)$. To form Q explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Q to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

The matrix Z is represented as a product of elementary reflectors

$$Z = H(ib) * H(ib+1) * \dots * H(ib+k-1), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{aub} * v * v'$$

where τ_{aub} is a real/complex scalar, and v is a real/complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(ib+n-k+i-1, jb:jb+p-k+i-2)$, and τ_{aub} in $\tau_{aub}(ib+n-k+i-1)$. To form Z explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungqr](#). To use Z to update another matrix, use ScaLAPACK subroutine [p?ormqr/p?unmqr](#).

p?ggrqf

Computes the generalized RQ factorization.

Syntax

```
call psggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)
```

```
call pdggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)
```

```
call pcggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)
```

```
call pzggrqf(m, p, n, a, ia, ja, desca, taua, b, ib, jb, descb, taub, work,
lwork, info)
```

Description

The routine forms the generalized RQ factorization of an m -by- n matrix $\text{sub}(A) = (ia:ia+m-1, ja:ja+n-1)$ and a p -by- n matrix $\text{sub}(B) = (ib:ib+p-1, ja:ja+n-1)$:

$$\text{sub}(A) = R^*Q, \quad \text{sub}(B) = Z^*T^*Q,$$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

$$R = \begin{pmatrix} m & 0 & R_{12} \\ n-m & m & \end{pmatrix}, \text{ if } m \leq n,$$

or

$$R = \begin{pmatrix} R_{11} & m-n \\ R_{12} & n \end{pmatrix}, \text{ if } m > n$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} T_{11} \\ 0 \end{pmatrix} \begin{matrix} n \\ p - n \end{matrix}, \text{ if } p \geq n$$

or

$$T = \begin{pmatrix} T_{11} & T_{12} \\ & \end{pmatrix} \begin{matrix} p \\ n - p \end{matrix}, \text{ if } p < n,$$

where T^{11} is upper triangular.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GRQ factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the RQ factorization of $\text{sub}(A) * \text{inv}(\text{sub}(B))$:

$$\text{sub}(A) * \text{inv}(\text{sub}(B)) = (R * \text{inv}(T)) * Z'$$

where $\text{inv}(\text{sub}(B))$ denotes the inverse of the matrix $\text{sub}(B)$, and Z' denotes the transpose (conjugate transpose) of matrix Z .

Input Parameters

m	(global) INTEGER. The number of rows in the distributed matrices $\text{sub}(A)$ ($m \geq 0$).
p	INTEGER. The number of rows in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
a	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+n-1))$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb+n-1)</i>). Contains the local pieces of the <i>p</i> -by- <i>n</i> matrix sub(<i>B</i>) to be factored.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) REAL for psggrqf DOUBLE PRECISION for pdggrqf COMPLEX for pcggrqf DOUBLE COMPLEX for pzggrqf. Workspace array of dimension of <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Dimension of <i>work</i> , must be at least <i>lwork</i> ≥ $\max(\text{mb\_a} * (\text{mpa0} + \text{nqa0} + \text{mb\_a}),$ $\max((\text{mb\_a} * (\text{mb\_a} - 1)) / 2, (\text{ppb0} + \text{nqb0}) * \text{mb\_a}) +$ $\text{mb\_a} * \text{mb\_a}, \text{nb\_b} * (\text{ppb0} + \text{nqb0} + \text{nb\_b})), \text{ where}$ $\text{irow} = \text{indxg2p}(\text{ia}, \text{mb\_a}, \text{MYROW}, \text{rsrc\_a}, \text{NPROW}),$ $\text{iacol} = \text{indxg2p}(\text{ja}, \text{nb\_a}, \text{MYCOL}, \text{csrc\_a}, \text{NPCOL}),$ $\text{mpa0} = \text{numroc}(\text{m} + \text{irow}, \text{mb\_a}, \text{MYROW}, \text{iarow},$ $\text{NPROW}),$

```

nqa0 = numroc (m+icoffa, nb_a, MYCOL, iacol,
NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW
),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL
),
ppb0 = numroc (p+iroffb, mb_b, MYROW, ibrow,
NPROW),
nqb0 = numroc (n+icoffb, nb_b, MYCOL, ibcol,
NPCOL)

```

and numroc, indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a

On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array *taua*, represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors (see *Application Notes* below).

taua, taub

(local)

REAL for psggqrf

DOUBLE PRECISION for pdggqrf

COMPLEX for pcggqrf

DOUBLE COMPLEX for pzggqrf.

Arrays, DIMENSION *LOCr*(*ia+m-1*) for *taua* and *LOCc*(*jb+min(p, n)-1*) for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*. *taua* is tied to the distributed matrix *A*. (See *Application Notes* below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See *Application Notes* below).

work(1)

On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info

(global) INTEGER.

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_{aua} v v'$$

where τ_{aua} is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ_{aua} in $\tau_{aua}(ia+m-k+i-1)$. To form *Q* explicitly, use ScaLAPACK subroutine [p?orgqr/p?ungrq](#). To use *Q* to update another matrix, use ScaLAPACK subroutine [p?ormrq/p?unmrq](#).

The matrix *Z* is represented as a product of elementary reflectors

$$Z = H(jb) * H(jb+1) * \dots * H(jb+k-1), \text{ where } k = \min(p, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{aub} v v'$$

where taub is a real/complex scalar, and v is a real/complex vector with $\mathit{v}(1:i-1) = 0$ and $\mathit{v}(i) = 1$; $\mathit{v}(i+1:p)$ is stored on exit in $\mathit{B}(\mathit{ib}+i:\mathit{ib}+p-1, \mathit{jb}+i-1)$, and taub in $\mathit{taub}(\mathit{jb}+i-1)$. To form z explicitly, use ScaLAPACK subroutine `p?orgqr/p?ungqr`. To use z to update another matrix, use ScaLAPACK subroutine `p?ormqr/p?unmqr`.

Symmetric Eigenproblems

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form T and then find the eigenvalues and eigenvectors of the tridiagonal matrix T . ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $\mathit{A} = \mathit{Q}\mathit{T}\mathit{Q}^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table 6-4](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the $\mathit{Q}\mathit{T}\mathit{Q}$ algorithm, or bisection followed by inverse iteration).

Table 6-4 Computational Routines for Solving Symmetric Eigenproblems

Operation	Dense symmetric/Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Reduce to tridiagonal form $\mathit{A} = \mathit{Q}\mathit{T}\mathit{Q}^H$	<code>p?sytrd/p?hetrd</code>		
Multiply matrix after reduction		<code>p?ormtr/p?unmtr</code>	
Find all eigenvalues and eigenvectors of a tridiagonal matrix T by a $\mathit{Q}\mathit{T}\mathit{Q}$ method			<code>steqr2</code> *)
Find selected eigenvalues of a tridiagonal matrix T via bisection			<code>p?stebz</code>
Find selected eigenvectors of a tridiagonal matrix T by inverse iteration			<code>p?stein</code>

*) This routine is described as part of auxiliary ScaLAPACK routines.

p?sytrd

Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.

Syntax

```
call pssytrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

This routine reduces a real symmetric matrix $\text{sub}(A)$ to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q' * \text{sub}(A) * Q = T,$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is stored: If <i>uplo</i> = 'U', upper triangular If <i>uplo</i> = 'L', lower triangular
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the symmetric distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

	If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See <i>Application Notes</i> below.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB),$ where $NB = mb\_a = nb\_a$, $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc\_a, NPROW)$. indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pserbla</code> .

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with

the array *tau*, represent the orthogonal matrix *Q* as a product of elementary reflectors. See *Application Notes* below.

<i>d</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays, DIMENSION <i>LOCc</i>(<i>ja+n-1</i>) .The diagonal elements of the tridiagonal matrix <i>T</i>: <i>d</i>(<i>i</i>) = <i>A</i>(<i>i</i>,<i>i</i>) . <i>d</i> is tied to the distributed matrix <i>A</i>.
<i>e</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays, DIMENSION <i>LOCc</i>(<i>ja+n-1</i>) if <i>uplo</i> = 'U', <i>LOCc</i>(<i>ja+n-2</i>) otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i>: <i>e</i>(<i>i</i>) = <i>A</i>(<i>i</i>,<i>i+1</i>) if <i>uplo</i> = 'U', <i>e</i>(<i>i</i>) = <i>A</i>(<i>i+1</i>,<i>i</i>) if <i>uplo</i> = 'L'. <i>e</i> is tied to the distributed matrix <i>A</i>.
<i>tau</i>	(local) REAL for pssytrd DOUBLE PRECISION for pdsytrd. Arrays, DIMENSION <i>LOCc</i>(<i>ja+n-1</i>) . This array contains the scalar factors <i>tau</i> of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>work</i> (1)	On exit <i>work</i>(1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <i>info</i> = - (<i>i</i>* 100+<i>j</i>), if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The contents of $sub(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If $uplo = 'L'$:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and $v\ i$ denotes an element of the vector defining $H(i)$.

p?ormtr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.

Syntax

```
call psormtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdormtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of nq elementary reflectors, as returned by p?sytrd.

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied.
$uplo$	(global) CHARACTER.

	= 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from $p?sytrd$; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from $p?sytrd$
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $sub(C)$ ($n \geq 0$).
<i>a</i>	(local) REAL for $psormtr$ DOUBLE PRECISION for $pdormtr$. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+m-1))$ if $side='L'$, or $(lld\_a, LOCC(ja+n-1))$ if $side = 'R'$. Contains the vectors which define the elementary reflectors, as returned by $p?sytrd$. If $side='L', lld\_a \geq \max(1, LOCr(ia+m-1))$; If $side = 'R', lld\_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for $psormtr$ DOUBLE PRECISION for $pdormtr$. Array, DIMENSION of <i>ltau</i> where if $side = 'L'$ and $uplo = 'U'$, $ltau = LOCC(m\_a)$, if $side = 'L'$ and $uplo = 'L'$, $ltau = LOCC(ja+m-2)$, if $side = 'R'$ and $uplo = 'U'$, $ltau = LOCC(n\_a)$, if $side = 'R'$ and $uplo = 'L'$, $ltau = LOCC(ja+n-2)$. $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by $p?sytrd$. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) REAL for $psormtr$

	DOUBLE PRECISION for pdormtr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja+n-1</i>)). Contains the local pieces of the distributed matrix sub (<i>c</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>desc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) REAL for psormtr DOUBLE PRECISION for pdormtr. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: <pre> if uplo = 'U', iaa= ia; jaa= ja+1, icc= ic; jcc= jc; else uplo = 'L', iaa= ia+1, jaa= ja; If side = 'L', icc= ic+1; jcc= jc; else icc= ic; jcc= jc+1; end if end if If side = 'L', mi= m-1; ni= n lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a else If side = 'R', mi= m; ni = n-1; lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a)+ nb_a*nb_a end if </pre>

where $lcmq = lcm/NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,

```

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

$ilcm$, $indxg2p$ and $numroc$ are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the subroutine `blacs_gridinfo`. If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c	Overwritten by the product $Q*\text{sub}(c)$, or $Q'*\text{sub}(c)$, or $\text{sub}(c)*Q'$, or $\text{sub}(c)*Q$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?hetrd

Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.

Syntax

```
call pchetrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetrd( uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

This routine reduces a complex Hermitian matrix $\text{sub}(A)$ to Hermitian tridiagonal form T by a unitary similarity transformation:

$$Q'^* \text{sub}(A) Q = T$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the Hermitian matrix $\text{sub}(A)$ is stored: If <i>uplo</i> = 'U', upper triangular If <i>uplo</i> = 'L', lower triangular
<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) COMPLEX for pchetrd DOUBLE COMPLEX for pzhetrd. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

	If <code>uplo = 'L'</code>, the leading n-by-n lower triangular part of <code>sub(A)</code> contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see <i>Application Notes</i> below).
<code>ia, ja</code>	(global) <code>INTEGER</code>. The row and column indices in the global array <code>a</code> indicating the first row and the first column of the submatrix <code>A</code>, respectively.
<code>desca</code>	(global and local) <code>INTEGER</code> array, dimension (<code>dlen_</code>). The array descriptor for the distributed matrix <code>A</code>.
<code>work</code>	(local) <code>COMPLEX</code> for <code>pchetrd</code> <code>DOUBLE COMPLEX</code> for <code>pzhetrdr</code>. Workspace array of dimension <code>lwork</code>.
<code>lwork</code>	(local or global) <code>INTEGER</code>, dimension of <code>work</code>, must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB)$ where $NB = mb\_a = nb\_a$, $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc\_a, NPROW)$. <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <code>MYROW</code>, <code>MYCOL</code>, <code>NPROW</code> and <code>NPCOL</code> can be determined by calling the subroutine <code>blacs_gridinfo</code>. If <code>lwork = -1</code>, then <code>lwork</code> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code>.

Output Parameters

<code>a</code>	On exit, If <code>uplo = 'U'</code>, the diagonal and first superdiagonal of <code>sub(A)</code> are overwritten by the corresponding elements of the tridiagonal matrix <code>T</code>, and the elements above the first superdiagonal, with the array <code>tau</code>, represent the unitary matrix <code>Q</code> as a product of elementary reflectors; if <code>uplo = 'L'</code>, the diagonal and first subdiagonal of <code>sub(A)</code> are overwritten by the corresponding elements of the tridiagonal

	matrix T , and the elements below the first subdiagonal, with the array τ , represent the unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
d	(local) REAL for pchetrd DOUBLE PRECISION for pzhetrd. Arrays, DIMENSION $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T: $d(i) = A(i, i)$. d is tied to the distributed matrix A.
e	(local) REAL for pchetrd DOUBLE PRECISION for pzhetrd. Arrays, DIMENSION $LOCc(ja+n-1)$ if $uplo = 'U'$; $LOCc(ja+n-2)$ - otherwise. The off-diagonal elements of the tridiagonal matrix T: $e(i) = A(i, i+1)$ if $uplo = 'U'$, $e(i) = A(i+1, i)$ if $uplo = 'L'$. e is tied to the distributed matrix A.
τ	(local) COMPLEX for pchetrd DOUBLE COMPLEX for pzhetrd. Arrays, DIMENSION $LOCc(ja+n-1)$. This array contains the scalar factors τ of the elementary reflectors. τ is tied to the distributed matrix A.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i-th argument is an array and the j-entry had an illegal value, then $info = -(i*100+j)$, if the i-th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If $uplo = 'L'$:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and $v\ i$ denotes an element of the vector defining $H(i)$.

p?unmtr

Multiplies a general matrix by the unitary transformation matrix from a reduction to tridiagonal form determined by p?hetrd.

Syntax

```
call pcunmtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunmtr( side, uplo, trans, m, n, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'C':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $nq-1$ elementary reflectors, as returned by p?hetrd.

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

$side$	(global) CHARACTER $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right.
$trans$	(global) CHARACTER $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied.
$uplo$	(global) CHARACTER.

	= 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?hetrd</code>; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?hetrd</code>
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix <code>sub(c)</code> ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix <code>sub(c)</code> ($n \geq 0$).
<i>a</i>	(local) REAL for <code>pcunmtr</code> DOUBLE PRECISION for <code>pzunmtr</code>. Pointer into the local memory to an array of dimension $(lld\_a, LOCc(ja+m-1))$ if <code>side='L'</code>, or $(lld\_a, LOCc(ja+n-1))$ if <code>side = 'R'</code>. Contains the vectors which define the elementary reflectors, as returned by <code>p?hetrd</code>. If <code>side='L'</code>, $lld\_a \geq \max(1, LOCr(ia+m-1))$; If <code>side = 'R'</code>, $lld\_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for <code>pcunmtr</code> DOUBLE COMPLEX for <code>pzunmtr</code>. Array, DIMENSION of <i>ltau</i> where If <code>side = 'L'</code> and <code>uplo = 'U'</code>, $ltau = LOCc(m\_a)$, if <code>side = 'L'</code> and <code>uplo = 'L'</code>, $ltau = LOCc(ja+m-2)$, if <code>side = 'R'</code> and <code>uplo = 'U'</code>, $ltau = LOCc(n\_a)$, if <code>side = 'R'</code> and <code>uplo = 'L'</code>, $ltau = LOCc(ja+n-2)$. <i>tau(i)</i> must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>p?hetrd</code>. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) COMPLEX for <code>pcunmtr</code>

	DOUBLE COMPLEX for pzunmtr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)). Contains the local pieces of the distributed matrix sub (<i>c</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) COMPLEX for pcunmtr DOUBLE COMPLEX for pzunmtr. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>uplo</i> = 'U', <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> +1, <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> ; else <i>uplo</i> = 'L', <i>iaa</i> = <i>ia</i> +1, <i>jaa</i> = <i>ja</i> ; If <i>side</i> = 'L', <i>icc</i> = <i>ic</i> +1; <i>jcc</i> = <i>jc</i> ; else <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> +1; end if end if If <i>side</i> = 'L', <i>mi</i> = <i>m</i> -1; <i>ni</i> = <i>n</i> <i>lwork</i> ≥ max((<i>nb_a</i> *(<i>nb_a</i> -1))/2, (<i>nqc0</i> + <i>mpc0</i>)* <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> else If <i>side</i> = 'R', <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> -1; <i>lwork</i> ≥ max((<i>nb_a</i> *(<i>nb_a</i> -1))/2, (<i>nqc0</i> + max(<i>npa0</i> +numroc(numroc(<i>ni</i> + <i>icoffc</i> , <i>nb_a</i> , 0, 0, NPCOL), <i>nb_a</i> , 0, 0, <i>lcmq</i>), <i>mpc0</i>))* <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> end if

where $lcmq = lcm/NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,

```

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo. If lwork = -1,
then lwork is global input and a workspace query is
assumed; the routine only calculates the minimum and
optimal size for all work arrays. Each of these values is
returned in the first entry of the corresponding work array,
and no error message is issued by p_xerbla.

```

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(c)$, or $Q' \cdot \text{sub}(c)$, or $\text{sub}(c) \cdot Q'$, or $\text{sub}(c) \cdot Q$.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - <i>i</i>

p?stebz

Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.

Syntax

```
call psstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit,
w, iblock, isplit, work, iwork, liwork, info)

call pdstebz(ictxt, range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit,
w, iblock, isplit, work, iwork, liwork, info)
```

Description

This routine computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval $[vl\ vu]$, or the eigenvalues indexed il through iu . A static partitioning of work is done at the beginning of `p?stebz` which results in all processes finding an (almost) equal number of eigenvalues.

Input Parameters

<code>ictxt</code>	(global) INTEGER. The BLACS context handle.
<code>range</code>	(global) CHARACTER. Must be 'A' or 'V' or 'I'. If <code>range</code> = 'A', the routine computes all eigenvalues. If <code>range</code> = 'V', the routine computes eigenvalues in the interval $[vl, vu]$. If <code>range</code> = 'I', the routine computes eigenvalues with indices il to iu .
<code>order</code>	(global) CHARACTER. Must be 'B' or 'E'. If <code>order</code> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block. If <code>order</code> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.
<code>n</code>	(global) INTEGER. The order of the tridiagonal matrix T ($n \geq 0$).
<code>vl, vu</code>	(global) REAL for <code>psstebz</code> DOUBLE PRECISION for <code>pdstebz</code> .

If *range* = 'V', the routine computes the lower and the upper bounds for the eigenvalues on the interval [*l*, *vu*].
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu
 (global)
 INTEGER. Constraint: $1 \leq il \leq iu \leq n$.
 If *range* = 'I', the index of the smallest eigenvalue is returned for *il* and of the largest eigenvalue for *iu* (assuming that the eigenvalues are in ascending order) must be returned. *il* must be at least 1. *iu* must be at least *il* and no greater than *n*.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol
 (global)
 REAL for psstebz
 DOUBLE PRECISION for pdstebz.
 The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*. If *abstol* ≤ 0, then the tolerance is taken as $ulp ||T||$, where *ulp* is the machine precision, and $||T||$ means the 1-norm of *T*. Eigenvalues will be computed most accurately when *abstol* is set to the underflow threshold `slamch('U')`, not 0. Note that if eigenvectors are desired later by inverse iteration (`p?stein`), *abstol* should be set to $2 * p?lamch('S')$.

d
 (global)
 REAL for psstebz
 DOUBLE PRECISION for pdstebz.
 Array, DIMENSION (*n*).
 Contains *n* diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

e
 (global)
 REAL for psstebz
 DOUBLE PRECISION for pdstebz.
 Array, DIMENSION (*n* - 1).

	Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix T . To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.
<i>work</i>	(local) REAL for psstebz DOUBLE PRECISION for pdstebz. Array, DIMENSION $\max(5n, 7)$. This is a workspace array.
<i>lwork</i>	(local) INTEGER. The size of the <i>work</i> array must be $\geq \max(5n, 7)$. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p _x erbla.
<i>iwork</i>	(local) INTEGER. Array, DIMENSION $\max(4n, 14)$. This is a workspace array.
<i>liwork</i>	(local) INTEGER. the size of the <i>iwork</i> array must $\geq \max(4n, 14, \text{NPROCS})$. If <i>liwork</i> = -1, then <i>liwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p _x erbla.

Output Parameters

<i>m</i>	(global) INTEGER. The actual number of eigenvalues found. $0 \leq m \leq n$
<i>nsplit</i>	(global) INTEGER. The number of diagonal blocks detected in T . $1 \leq \text{nsplit} \leq n$
<i>w</i>	(global) REAL for psstebz DOUBLE PRECISION for pdstebz.

iblock

Array, DIMENSION (n). On exit, the first m elements of w contain the eigenvalues on all processes.

(global) INTEGER.

Array, DIMENSION (n). At each row/column j where $e(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit *iblock*(i) specifies which block (from 1 to the number of blocks) the eigenvalue $w(i)$ belongs to.

NOTE. In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, *info* is set to 1 and the ones for which it did not are identified by a negative block number.

isplit

(global) INTEGER.

Array, DIMENSION (n).

Contains the splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to *isplit*(1), the second of rows/columns *isplit*(1)+1 through *isplit*(2), etc., and the *nsplit*-th consists of rows/columns *isplit*(*nsplit*-1)+1 through *isplit*(*nsplit*)= n . (Only the first *nsplit* elements are used, but since the *nsplit* values are not known, n words must be reserved for *isplit*.)

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0, if *info* = $-i$, the i -th argument has an illegal value.

If *info* > 0, some or all of the eigenvalues fail to converge or not computed.

If *info* = 1, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.

If *info* = 2, mismatch between the number of eigenvalues output and the number desired.

If `info = 3: range='i'`, and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating point arithmetic. Increase the `fudge` parameter, recompile, and try again.

p?stein

Computes the eigenvectors of a tridiagonal matrix using inverse iteration.

Syntax

```
call psstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)

call pdstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)

call pcstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)

call pzstein(n, d, e, m, w, iblock, isplit, orfac, z, iz, jz, descz, work,
lwork, iwork, liwork, ifail, iclustr, gap, info)
```

Description

This routine computes the eigenvectors of a symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK routine) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE. If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

p = `NPROW*NPCOL` is the total number of processes.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the matrix T ($n \geq 0$).
<i>m</i>	(global) INTEGER. The number of eigenvectors to be returned.
<i>d</i> , <i>e</i> , <i>w</i>	(global) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of T . DIMENSION (<i>n</i>). <i>e</i> (*) contains the off-diagonal elements of T . DIMENSION (<i>n</i> -1). <i>w</i> (*) contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array <i>w</i> from p?stebz with order = 'B' is expected. The array should be replicated in all processes.) DIMENSION(<i>m</i>)
<i>iblock</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). The submatrix indices associated with the corresponding eigenvalues in <i>w</i> --1 for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array <i>iblock</i> from p?stebz is expected here).
<i>isplit</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), etc., and the <i>nsplit</i> -th consists of rows/columns <i>isplit</i> (<i>nsplit</i> -1)+1 through <i>isplit</i> (<i>nsplit</i>)= <i>n</i> . (The output array <i>isplit</i> from p?stebz is expected here.)
<i>orfac</i>	(global) REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

	<i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within $orfac * T$ of each other are to be orthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if <i>orfac</i> is equal to zero. A default value of 1000 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local). REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Workspace array, DIMENSION (<i>lwork</i>).
<i>lwork</i>	(local) INTEGER. <i>lwork</i> controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is $nvec = \text{floor}((lwork - \max(5*n, np00*mq00)) / n)$. Eigenvectors corresponding to eigenvalue clusters of size $nvec - \text{ceil}(m/p) + 1$ are guaranteed to be orthogonal (the orthogonality is similar to that obtained from ?stein2).

NOTE. *lwork* must be no smaller than $\max(5*n, np00*mq00) + \text{ceil}(m/p)*n$ and should have the same input value on all processes.

It is the minimum value of *lwork* input on different processes that is significant.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

iwork (local) INTEGER.
Workspace array, DIMENSION (3n+p+1).

liwork (local) INTEGER. The size of the array *iwork*. It must be greater than (3*n+p+1).
If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

z (local)
REAL for *psstein*
DOUBLE PRECISION for *pdstein*
COMPLEX for *pcstein*
DOUBLE COMPLEX for *pzstein*.
Array, DIMENSION (*descz(dlen_)*, n/NPCOL + NB). *z* contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See [?stein2](#)). On output, *z* is distributed across the *p* processes in block cyclic format.

work(1) On exit, *work*(1) gives a lower bound on the workspace (*lwork*) that guarantees the user desired orthogonalization (see *orfac*). Note that this may overestimate the minimum workspace needed.

iwork On exit, *iwork*(1) contains the amount of integer workspace required.
On exit, the *iwork*(2) through *iwork*(p+2) indicate the eigenvectors computed by each process. Process *i* computes eigenvectors indexed *iwork*(i+2)+1 through *iwork*(i+3).

ifail (global). INTEGER. Array, DIMENSION (*m*). On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in [?stein](#)), then *info* > 0 is returned. If mod(*info*, m+1) > 0, then for *i*=1

to $\text{mod}(\text{info}, m+1)$, the eigenvector corresponding to the eigenvalue $w(\text{ifail}(i))$ failed to converge (w refers to the array of eigenvalues on output).

iclustr (global) INTEGER. Array, DIMENSION $(2*p)$
 This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $\text{iclustr}(2*I-1)$ to $\text{iclustr}(2*I)$, $i = 1$ to $\text{info}/(m+1)$, could not be orthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array
 $--- (\text{iclustr}(2*k) \neq 0 \text{ and } \text{iclustr}(2*k+1) = 0)$
 if and only if k is the number of clusters.

gap (global)
 REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
 This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The info/m output values in this array correspond to the $\text{info}/(m+1)$ clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(O(n) * \text{macheps}) / \text{gap}(i)$.

info (global) INTEGER.
 If $\text{info} = 0$, the execution is successful.
 If $\text{info} < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$,
 If the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.
 If $\text{info} < 0$: if $\text{info} = -i$, the i -th argument had an illegal value.
 If $\text{info} > 0$: if $\text{mod}(\text{info}, m+1) = i$, then i eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If $\text{info}/(m+1) = i$, then eigenvectors corresponding to i clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

Nonsymmetric Eigenvalue Problems

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table 6-5 lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Table 6-5 Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	<code>p?gehrd</code>	
Multiply the matrix after reduction		<code>p?ormhr/p?unmhr</code>
Find eigenvalues and Schur factorization		<code>p?lahqr</code>

p?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

```
call psgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehrd( n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine reduces a real/complex general distributed matrix sub (A) to upper Hessenberg form H by an orthogonal or unitary similarity transformation

$$Q'^* \text{sub}(A) * Q = H,$$

where $\text{sub}(A) = A(\text{ia}+n-1:\text{ia}+n-1, \text{ja}+n-1:\text{ja}+n-1)$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+n-1$ and columns $\text{ja}:\text{ja}+\text{ilo}-2$ and $\text{ja}+\text{ihi}:\text{ja}+n-1$. (See <i>Application Notes</i> below). If $n > 0$, $1 \leq \text{ilo} \leq \text{ihi} \leq n$; otherwise set $\text{ilo} = 1$, $\text{ihi} = n$.
<i>a</i>	(local) REAL for psgehrd DOUBLE PRECISION for pdgehrd COMPLEX for pcgehrd DOUBLE COMPLEX for pzgehrd. Pointer into the local memory to an array of dimension $(\text{lld\_a}, \text{LOCc}(\text{ja}+n-1))$. On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (dlen_) . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for psgehrd DOUBLE PRECISION for pdgehrd COMPLEX for pcgehrd DOUBLE COMPLEX for pzgehrd. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $\text{lwork} \geq \text{NB} * \text{NB} + \text{NB} * \max(\text{ihlp}+1, \text{ihlp}+\text{inlq})$ where $\text{NB} = \text{mb\_a} = \text{nb\_a}$, $\text{iroffa} = \text{mod}(\text{ia}-1, \text{NB})$,

```

icoffa = mod(ja-1, NB),
ioff = mod(ia+ilo-2, NB), iarow = indxg2p(ia,
NB, MYROW, rsrc_a, NPROW), ihip =
numroc(ihi+ioffa, NB, MYROW, iarow, NPROW),
ilrow = indxg2p(ia+ilo-1, NB, MYROW, rsrc_a,
NPROW),
ihlp = numroc(ihi-ilo+ioff+1, NB, MYROW, ilrow,
NPROW),
ilcol = indxg2p(ja+ilo-1, NB, MYCOL, csrc_a,
NPCOL),
inlq = numroc(n-ilo+ioff+1, NB, MYCOL, ilcol,
NPCOL),
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pserbla`.

Output Parameters

<code>a</code>	On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local). REAL for <code>psgehrd</code> DOUBLE PRECISION for <code>pdgehrd</code> COMPLEX for <code>pcgehrd</code> DOUBLE COMPLEX for <code>pzgehrd</code> . Array, DIMENSION at least $\max(ja+n-2)$. The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements <code>ja:ja+ilo-2</code> and <code>ja+ihi:ja+n-2</code> of <code>tau</code> are set to zero. <code>tau</code> is tied to the distributed matrix A .

work(1) On exit *work*(1) contains the minimum value of *lwork* required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i** 100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix Q is represented as a product of ($ihi-ilo$) elementary reflectors

$$Q = H(ilo)*H(ilo+1)*\dots*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $a(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$, and τ in $\tau(ja+ilo+i-2)$. The contents of $a(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & a & a & a & a & a \\ & & & a & a & a & a \\ & & & & a & a & a \\ & & & & & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & & h & h & h & h & h \\ & & & v2 & h & h & h \\ & & & & v2 & v3 & h \\ & & & & & v2 & v3 & v4 & h & h & h \\ & & & & & & & & & a \end{bmatrix}$$

where a denotes an element of the original matrix $\text{sub}(A)$, H denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?ormhr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

```
call psormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

```
call pdormhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

The routine overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by p?gehrd.

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER ='L': Q or Q^T is applied from the left. ='R': Q or Q^T is applied from the right.
<i>trans</i>	(global) CHARACTER ='N', no transpose, Q is applied. ='T', transpose, Q^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub (<i>C</i>) ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (<i>C</i>) ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. <i>ilo</i> and <i>ihi</i> must have the same values as in the previous call of <code>p?gehrd</code> . Q is equal to the unit matrix except for the distributed submatrix $Q(ia+ilo:ia+ihi-1, ia+ilo:ja+ihi-1)$. If <i>side</i> = 'L', $1 \leq ilo \leq ihi \leq \max(1, m)$; If <i>side</i> = 'R', $1 \leq ilo \leq ihi \leq \max(1, n)$; <i>ilo</i> and <i>ihi</i> are relative indexes.
<i>a</i>	(local) REAL for <code>psormhr</code> DOUBLE PRECISION for <code>pdormhr</code> Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>m</i> -1)) if <i>side</i> ='L', and (<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)) if <i>side</i> = 'R'. Contains the vectors which define the elementary reflectors, as returned by <code>p?gehrd</code> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <code>psormhr</code>

	DOUBLE PRECISION for pdormhr Array, DIMENSION $LOCc(ja+m-2)$, if $side = 'L'$, and $LOCc(ja+n-2)$ if $side = 'R'$. This array contains the scalar factors $\tau(j)$ of the elementary reflectors $H(j)$ as returned by p?gehrd. τ is tied to the distributed matrix A .
c	(local) REAL for psormhr DOUBLE PRECISION for pdormhr Pointer into the local memory to an array of dimension ($lld\_c, LOCc(jc+n-1)$). Contains the local pieces of the distributed matrix sub(c).
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix c , respectively.
$descc$	(global and local) INTEGER array, dimension ($dlen\_$). The array descriptor for the distributed matrix c .
$work$	(local) REAL for psormhr DOUBLE PRECISION for pdormhr Workspace array with dimension $lwork$.
$lwork$	(local or global) INTEGER. The dimension of the array $work$. $lwork$ must be at least $iaa = ia + ilo; jaa =$ $ja + ilo - 1;$ If $side = 'L'$, $mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$ $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a$ $+ nb\_a * nb\_a$ else if $side = 'R'$, $mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo;$ $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2,$ $(nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb\_a,$ $0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) +$ $nb\_a * nb\_a$ end if

where $lcmq = lcm/NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(iaa-1, mb\_a)$,
 $icoffa = \text{mod}(jaa-1, nb\_a)$,
 $iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW)$,
 $npa0 = \text{numroc}(ni+iroffa, mb\_a, MYROW, iarow, NPROW)$,
 $iroffc = \text{mod}(icc-1, mb\_c)$, $icoffc = \text{mod}(jcc-1, nb\_c)$,
 $icrow = \text{indxg2p}(icc, mb\_c, MYROW, rsrc\_c, NPROW)$,
 $iccol = \text{indxg2p}(jcc, nb\_c, MYCOL, csrc\_c, NPCOL)$,
 $mpc0 = \text{numroc}(mi+iroffc, mb\_c, MYROW, icrow, NPROW)$,
 $nqc0 = \text{numroc}(ni+icoffc, nb\_c, MYCOL, iccol, NPCOL)$,
 $ilcm, \text{indxg2p}$ and numroc are ScaLAPACK tool functions;
 $MYROW, MYCOL, NPROW$ and $NPCOL$ can be determined by
calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p_xerbla`.

Output Parameters

c	$\text{sub}(c)$ is overwritten by $Q*\text{sub}(c)$, or $Q'*\text{sub}(c)$, or $\text{sub}(c)*Q'$, or $\text{sub}(c)*Q$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmhr

Multiplies a general matrix by the unitary transformation matrix from a reduction to Hessenberg form determined by p?gehrd.

Syntax

```
call pcunmhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)

call pzunmhr(side, trans, m, n, ilo, ihi, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

The routine overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'H':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by p?gehrd.

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

$side$	(global) CHARACTER = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
$trans$	(global) CHARACTER = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
m	(global) INTEGER. The number of rows in the distributed submatrix $\text{sub}(C)$ ($m \geq 0$).

<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix sub (<i>c</i>) ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to p?gehrd. <i>Q</i> is equal to the unit matrix except in the distributed submatrix <i>Q</i> (<i>ia+ilo:ia+ihi-1, ia+ilo:ja+ihi-1</i>). If <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq \max(1, m)$. If <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq \max(1, n)$ <i>ilo</i> and <i>ihi</i> are relative indexes.
<i>a</i>	(local) COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOC c(ja+m-1)</i>) if <i>side</i> ='L', and (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>) if <i>side</i> = 'R'. Contains the vectors which define the elementary reflectors, as returned by p?gehrd.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr. Array, DIMENSION <i>LOCc(ja+m-2)</i> , if <i>side</i> = 'L', and <i>LOCc(ja+n-2)</i> if <i>side</i> = 'R'. This array contains the scalar factors <i>tau(j)</i> of the elementary reflectors <i>H(j)</i> as returned by p?gehrd. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr. Pointer into the local memory to an array of dimension (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>).

<i>ic, jc</i>	Contains the local pieces of the distributed matrix sub(<i>c</i>). (global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>descc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) COMPLEX for pcunmhr DOUBLE COMPLEX for pzunmhr. Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	(local or global) The dimension of the array <i>work</i> . <i>lwork</i> must be at least <i>iaa</i> = <i>ia</i> + <i>ilo</i> ; <i>jaa</i> = <i>ja</i> + <i>ilo</i> - 1; If <i>side</i> = 'L', <i>mi</i> = <i>ihi</i> - <i>ilo</i> ; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> + <i>ilo</i> ; <i>jcc</i> = <i>jc</i> ; <i>lwork</i> ≥ max((<i>nb_a</i> * (<i>nb_a</i> - 1)) / 2, (<i>nqc0</i> + <i>mpc0</i>) * <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> else if <i>side</i> = 'R', <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>ihi</i> - <i>ilo</i> ; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> + <i>ilo</i> ; <i>lwork</i> ≥ max((<i>nb_a</i> * (<i>nb_a</i> - 1)) / 2, (<i>nqc0</i> + max(<i>npa0</i> + numroc(numroc(<i>ni</i> + <i>icoffc</i> , <i>nb_a</i> , 0, 0, NPCOL), <i>nb_a</i> , 0, 0, <i>lcmq</i>), <i>mpc0</i>)) * <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> end if where <i>lcmq</i> = <i>lcm</i> / NPCOL with <i>lcm</i> = <i>ilcm</i> (NPROW, NPCOL), <i>iroffa</i> = mod(<i>iaa</i> - 1, <i>mb_a</i>), <i>icoffa</i> = mod(<i>jaa</i> - 1, <i>nb_a</i>), <i>iarow</i> = indxg2p(<i>iaa</i> , <i>mb_a</i> , MYROW, <i>rsrc_a</i> , NPROW), <i>npa0</i> = numroc(<i>ni</i> + <i>iroffa</i> , <i>mb_a</i> , MYROW, <i>iarow</i> , NPROW), <i>iroffc</i> = mod(<i>icc</i> - 1, <i>mb_c</i>), <i>icoffc</i> = mod(<i>jcc</i> - 1, <i>nb_c</i>), <i>icrow</i> = indxg2p(<i>icc</i> , <i>mb_c</i> , MYROW, <i>rsrc_c</i> , NPROW), <i>iccol</i> = indxg2p(<i>jcc</i> , <i>nb_c</i> , MYCOL, <i>csrc_c</i> , NPCOL), <i>mpc0</i> = numroc(<i>mi</i> + <i>iroffc</i> , <i>mb_c</i> , MYROW, <i>icrow</i> , NPROW),

`nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),`
`ilcm, indxg2p` and `numroc` are ScaLAPACK tool functions;
`MYROW, MYCOL, NPROW` and `NPCOL` can be determined by
calling the subroutine `blacs_gridinfo`.
If `lwork = -1`, then `lwork` is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pserbla`.

Output Parameters

<code>c</code>	<code>c</code> is overwritten by $Q^* \text{sub}(c)$ or $Q'^* \text{sub}(c)$ or $\text{sub}(c)^* Q'$ or $\text{sub}(c)^* Q$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?lahqr

Computes the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form.

Syntax

```
call pslahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z,
descz, work, lwork, iwork, ilwork, info)

call pdlahqr(wantt, wantz, n, ilo, ihi, a, desca, wr, wi, iloz, ihiz, z,
descz, work, lwork, iwork, ilwork, info)
```

Description

This is an auxiliary routine used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

Input Parameters

<i>wantt</i>	(global) LOGICAL If <i>wantt</i> = .TRUE., the full Schur form <i>T</i> is required; If <i>wantt</i> = .FALSE., only eigenvalues are required.
<i>wantz</i>	(global) LOGICAL. If <i>wantz</i> = .TRUE., the matrix of Schur vectors <i>z</i> is required; If <i>wantz</i> = .FALSE., Schur vectors are not required.
<i>n</i>	(global) INTEGER. The order of the Hessenberg matrix <i>A</i> (and <i>z</i> if <i>wantz</i>). ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that <i>A</i> is already upper quasi-triangular in rows and columns <i>ihi</i> +1: <i>n</i> , and that $A(ilo, ilo-1) = 0$ (unless <i>ilo</i> = 1). <i>p?lahqr</i> works primarily with the Hessenberg submatrix in rows and columns <i>ilo</i> to <i>ihi</i> , but applies transformations to all of <i>h</i> if <i>wantt</i> is .TRUE.. $1 \leq ilo \leq \max(1, ihi); ihi \leq n$.
<i>a</i>	(global) REAL for <i>pslahqr</i> DOUBLE PRECISION for <i>pdlahqr</i> Array, DIMENSION (<i>desca</i> (<i>lld_</i>), *). On entry, the upper Hessenberg matrix <i>A</i> .
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iloz, ihiz</i>	(global) INTEGER. Specify the rows of <i>z</i> to which transformations must be applied if <i>wantz</i> is .TRUE.. $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$.
<i>z</i>	(global) REAL for <i>pslahqr</i> DOUBLE PRECISION for <i>pdlahqr</i>

	Array. If <i>wantz</i> is <code>.TRUE.</code> , on entry <i>z</i> must contain the current matrix <i>z</i> of transformations accumulated by <i>pdhseqr</i> . If <i>wantz</i> is <code>.FALSE.</code> , <i>z</i> is not referenced.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local) REAL for <i>pslahqr</i> DOUBLE PRECISION for <i>pdlahqr</i> Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	(local) INTEGER. The dimension of <i>work</i> . <i>lwork</i> is assumed big enough so that $lwork \geq 3*n + \max(2*\max(descz(lld_), desca(lld_)) + 2*LOCq(n), 7*ceil(n/hbl)/lcm(NPROW, NPCOL))$. If <i>lwork</i> = -1, then <i>work</i> (1) gets set to the above number and the code returns immediately.
<i>iwork</i>	(global and local) INTEGER array of size <i>ilwork</i> .
<i>ilwork</i>	(local) INTEGER This holds some of the <i>iblk</i> integer arrays.

Output Parameters

<i>a</i>	On exit, if <i>wantt</i> is <code>.TRUE.</code> , <i>A</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantt</i> is <code>.FALSE.</code> , the contents of <i>A</i> are unspecified on exit.
<i>work</i> (1)	On exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance.
<i>wr</i> , <i>wi</i>	(global replicated output) REAL for <i>pslahqr</i> DOUBLE PRECISION for <i>pdlahqr</i> Arrays, DIMENSION(<i>n</i>) each. The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)-th, with <i>wi</i> (<i>i</i>) > 0 and <i>wi</i> (<i>i</i> +1) < 0. If <i>wantt</i> is <code>.TRUE.</code> , the eigenvalues are stored in the same

order as on the diagonal of the Schur form returned in *A*. *A* may be returned with larger diagonal blocks until the next release.

z On exit *z* has been updated; transformations are applied only to the submatrix *z*(*iloz:ihiz*, *ilo:ihi*).

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: parameter number *-info* incorrect or inconsistent
 > 0: p?lahqr failed to compute all the eigenvalues *ilo* to *ihi* in a total of 30*(*ihi-ilo+1*) iterations; if *info* = *i*, elements *i+1:ihi* of *wr* and *wi* contain those eigenvalues which have been successfully computed.

Singular Value Decomposition

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general *m*-by-*n* matrix *A* (see “Singular Value Decomposition” in LAPACK chapter).

To find the SVD of a general matrix *A*, this matrix is first reduced to a bidiagonal matrix *B* by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of *B* is computed using the LAPACK routine ?bdsqr .

Table 6-6 lists ScaLAPACK computational routines for performing this decomposition.

Table 6-6 Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce <i>A</i> to a bidiagonal matrix	p?gebrd	
Multiply matrix after reduction		p?ormbr/p?unmbr

p?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

```
call psgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebrd(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Description

The routine reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q' * \text{sub}(A) * P = B.$$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

Input Parameters

m	(global) INTEGER. The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) INTEGER. The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Real pointer into the local memory to an array of dimension $(\text{lld\_a}, \text{LOCc}(\text{ja}+n-1))$. On entry, this array contains the distributed matrix $\text{sub}(A)$.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
desca	(global and local) INTEGER array, dimension (dlen_) . The array descriptor for the distributed matrix A .
work	(local) REAL for psgebrd DOUBLE PRECISION for pdgebrd COMPLEX for pcgebrd DOUBLE COMPLEX for pzgebrd. Workspace array of dimension lwork .
lwork	(local or global) INTEGER, dimension of work , must be at least: $\text{lwork} \geq \text{nb} * (\text{mpa0} + \text{nqa0} + 1) + \text{nqa0}$

```

where  $nb = mb\_a = nb\_a$ ,
 $iroffa = \text{mod}(ia-1, nb)$ ,
 $icoffa = \text{mod}(ja-1, nb)$ ,
 $iarow = \text{indxg2p}(ia, nb, MYROW, rsrc\_a, NPROW)$ ,
 $iacol = \text{indxg2p}(ja, nb, MYCOL, csrc\_a, NPCOL)$ ,
 $mpa0 = \text{numroc}(m + iroffa, nb, MYROW, iarow, NPROW)$ ,
 $nqa0 = \text{numroc}(n + icoffa, nb, MYCOL, iacol, NPCOL)$ ,
 $\text{indxg2p}$  and  $\text{numroc}$  are ScaLAPACK tool functions;  $MYROW$ ,  $MYCOL$ ,  $NPROW$  and  $NPCOL$  can be determined by calling the subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pzerbla`.

Output Parameters

a

On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array taup , represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array tauq , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array taup , represent the orthogonal matrix P as a product of elementary reflectors. See *Application Notes* below.

d

(local)

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors. Array,
 DIMENSION $LOCc(ja+\min(m,n)-1)$ if $m \geq n$;
 $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal
 elements of the bidiagonal matrix B : $d(i) = a(i,i)$.
 d is tied to the distributed matrix A .

e (local)
 REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors. Array,
 DIMENSION $LOCr(ia+\min(m,n)-1)$ if $m \geq n$;
 $LOCc(ja+\min(m,n)-2)$ otherwise. The distributed
 off-diagonal elements of the bidiagonal distributed matrix
 B :
 If $m \geq n$, $e(i) = a(i,i+1)$ for $i = 1, 2, \dots, n-1$; if m
 $< n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$. e is tied
 to the distributed matrix A .

tauq, taup (local)
 REAL for psgebrd
 DOUBLE PRECISION for pdgebrd
 COMPLEX for pcgebrd
 DOUBLE COMPLEX for pzgebrd.
 Arrays, DIMENSION $LOCc(ja+\min(m,n)-1)$ for *tauq* and
 $LOCr(ia+\min(m,n)-1)$ for *taup*. Contain the scalar factors
 of the elementary reflectors which represent the
 orthogonal/unitary matrices Q and P , respectively. *tauq* and
taup are tied to the distributed matrix A . See *Application*
Notes below.

work(1) On exit *work(1)* contains the minimum value of *lwork*
 required for optimum performance.

info (global) INTEGER.
 = 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -entry had
 an illegal value, then $info = -(i*100+j)$, if the i -th
 argument is a scalar and had an illegal value, then $info =$
 $-i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) * H(2) * \dots * H(n), \text{ and } P = G(1) * G(2) * \dots * G(n-1).$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{uq} * v * v' \text{ and } G(i) = I - \tau_{up} * u * u'$$

where τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{uq} is stored in $\tau_{uq}(ja+i-1)$ and τ_{up} in $\tau_{up}(ia+i-1)$.

If $m < n$,

$$Q = H(1) * H(2) * \dots * H(m-1), \text{ and } P = G(1) * G(2) * \dots * G(m)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{uq} * v * v' \text{ and } G(i) = I - \tau_{up} * u * u'$$

here τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{uq} is stored in $\tau_{uq}(ja+i-1)$ and τ_{up} in $\tau_{up}(ia+i-1)$.

The contents of sub(A) on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6$ ($m < n$):

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

p?ormbr

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
call psormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

```
call pdormbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

If $vect = 'Q'$, the routine overwrites the general real distributed m -by- n matrix $sub(C) = C(c:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q \ sub(C)$	$sub(C) \ Q$
$trans = 'T':$	$Q^T \ sub(C)$	$sub(C) \ Q^T$

If $vect = 'P'$, the routine overwrites $sub(C)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P \ sub(C)$	$sub(C) \ P$
$trans = 'T':$	$P^T \ sub(C)$	$sub(C) \ P^T$

Here Q and P^T are the orthogonal distributed matrices determined by `p?gebrd` when reducing a real distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q*B*P^T$. Q and P^T are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Thus nq is the order of the orthogonal matrix Q or P^T that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

<i>vect</i>	(global) CHARACTER. If $vect = 'Q'$, then Q or Q^T is applied. If $vect = 'P'$, then P or P^T is applied.
<i>side</i>	(global) CHARACTER. If $side = 'L'$, then Q or Q^T , P or P^T is applied from the left. If $side = 'R'$, then Q or Q^T , P or P^T is applied from the right.
<i>trans</i>	(global) CHARACTER. If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'T'$, then Q^T or P^T is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix sub (<i>C</i>).
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix sub (<i>C</i>).
<i>k</i>	(global) INTEGER. If $vect = 'Q'$, the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If $vect = 'P'$, the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$.

<i>a</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr. Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+min(<i>nq</i>,<i>k</i>)-1)) If <i>vect</i>='Q', and (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>nq</i>-1)) If <i>vect</i> = 'P'. <i>nq</i> = <i>m</i> if <i>side</i> = 'L', and <i>nq</i> = <i>n</i> otherwise. The vectors which define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P, as returned by p?gebrd. If <i>vect</i> = 'Q', <i>lld_a</i> ≥ max(1, <i>LOCr</i>(<i>ia</i>+<i>nq</i>-1)); If <i>vect</i> = 'P', <i>lld_a</i> ≥ max(1, <i>LOCr</i>(<i>ia</i>+min(<i>nq</i>, <i>k</i>)-1)).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr. Array, DIMENSION <i>LOCc</i>(<i>ja</i>+min(<i>nq</i>, <i>k</i>)-1), if <i>vect</i> = 'Q', and <i>LOCr</i>(<i>ia</i>+min(<i>nq</i>, <i>k</i>)-1), if <i>vect</i> = 'P'. <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P, as returned by pdgebrd in its array argument <i>tauq</i> or <i>taup</i>. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) REAL for psormbr DOUBLE PRECISION for pdormbr Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc</i> (<i>jc</i>+<i>n</i>-1)). Contains the local pieces of the distributed matrix sub (<i>c</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.

<i>desc</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) REAL for <i>psormbr</i> DOUBLE PRECISION for <i>pdormbr</i> . Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L' <i>nq</i> = <i>m</i> ; if ((<i>vect</i> = 'Q' and <i>nq</i> ≥ <i>k</i>) or (<i>vect</i> is not equal to 'Q' and <i>nq</i> > <i>k</i>)), <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> ; <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> ; else <i>iaa</i> = <i>ia</i> +1; <i>jaa</i> = <i>ja</i> ; <i>mi</i> = <i>m</i> -1; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> +1; <i>jcc</i> = <i>jc</i> ; end if else If <i>side</i> = 'R', <i>nq</i> = <i>n</i> ; if ((<i>vect</i> = 'Q' and <i>nq</i> ≥ <i>k</i>) or (<i>vect</i> is not equal to 'Q' and <i>nq</i> > <i>k</i>)), <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> ; <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> ; else <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> +1; <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> -1; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> +1; end if end if If <i>vect</i> = 'Q', If <i>side</i> = 'L', <i>lwork</i> ≥ max((<i>nb_a</i> *(<i>nb_a</i> -1))/2, (<i>nqc0</i> + <i>mpc0</i>)* <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> else if <i>side</i> = 'R', <i>lwork</i> ≥ max((<i>nb_a</i> *(<i>nb_a</i> -1))/2, (<i>nqc0</i> + max(<i>npa0</i> + numroc(numroc(<i>ni</i> + <i>icoffc</i> , <i>nb_a</i> , 0, 0, NPCOL), <i>nb_a</i> , 0, 0, <i>lcmq</i>), <i>mpc0</i>))* <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> end if else if <i>vect</i> is not equal to 'Q', if <i>side</i> = 'L',

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + max(mqa0 +

indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

<code>c</code>	On exit, if <code>vect='Q'</code> , <code>sub(c)</code> is overwritten by $Q*\text{sub}(c)$, or $Q'^*\text{sub}(c)$, or $\text{sub}(c)*Q'$, or $\text{sub}(c)*Q$; if <code>vect='P'</code> , <code>sub(c)</code> is overwritten by $P*\text{sub}(c)$, or $P'^*\text{sub}(c)$, or $\text{sub}(c)*P$, or $\text{sub}(c)*P'$.
<code>work(1)</code>	On exit <code>work(1)</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) INTEGER. = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info</code> = - (<i>i</i> * 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = - <i>i</i> .

p?unmbr

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
call pcunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)

call pzunmbr(vect, side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc,
descc, work, lwork, info)
```

Description

If `vect = 'Q'`, the routine overwrites the general complex distributed *m*-by-*n* matrix `sub(c)` = `C(ic:ic+m-1, jc:jc+n-1)` with

	<code>side = 'L'</code>	<code>side = 'R'</code>
<code>trans = 'N':</code>	$Q*\text{sub}(c)$	$\text{sub}(c)*Q$
<code>trans = 'C':</code>	$Q^H*\text{sub}(c)$	$\text{sub}(c)*Q^H$

If `vect = 'P'`, the routine overwrites `sub(c)` with

<code>side = 'L'</code>	<code>side = 'R'</code>

$trans = 'N':$	$P * sub(C)$	$sub(C) * P$
$trans = 'C':$	$P^H * sub(C)$	$sub(C) * P^H$

Here Q and P^H are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q * B * P^H$.

Q and P^H are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Thus nq is the order of the unitary matrix Q or P^H that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

<i>vect</i>	(global) CHARACTER. If $vect = 'Q'$, then Q or Q^H is applied. If $vect = 'P'$, then P or P^H is applied.
<i>side</i>	(global) CHARACTER. If $side = 'L'$, then Q or Q^H , P or P^H is applied from the left. If $side = 'R'$, then Q or Q^H , P or P^H is applied from the right.
<i>trans</i>	(global) CHARACTER. If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'C'$, conjugate transpose, Q^H or P^H is applied.
<i>m</i>	(global) INTEGER. The number of rows in the distributed matrix $sub(C)$ $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns in the distributed matrix $sub(C)$ $n \geq 0$.
<i>k</i>	(global) INTEGER.

	If <code>vect = 'Q'</code>, the number of columns in the original distributed matrix reduced by <code>p?gebrd</code>; If <code>vect = 'P'</code>, the number of rows in the original distributed matrix reduced by <code>p?gebrd</code>. Constraints: $k \geq 0$.
<i>a</i>	(local) COMPLEX for <code>psormbr</code> DOUBLE COMPLEX for <code>pdormbr</code>. Pointer into the local memory to an array of dimension $(lld\_a, LOCc(ja+\min(nq, k)-1))$ if <code>vect='Q'</code>, and $(lld\_a, LOCc(ja+nq-1))$ if <code>vect = 'P'</code>. $nq = m$ if <code>side = 'L'</code>, and $nq = n$ otherwise. The vectors which define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P, as returned by <code>p?gebrd</code>. If <code>vect = 'Q'</code>, $lld\_a \geq \max(1, LOCr(ia+nq-1))$; If <code>vect = 'P'</code>, $lld\_a \geq \max(1, LOCr(ia+\min(nq, k)-1))$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) COMPLEX for <code>pcunmbr</code> DOUBLE COMPLEX for <code>pzunmbr</code>. Array, DIMENSION $LOCc(ja+\min(nq, k)-1)$, if <code>vect = 'Q'</code>, and $LOCr(ia+\min(nq, k)-1)$, if <code>vect = 'P'</code>. <i>tau</i>(<i>i</i>) must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P, as returned by <code>p?gebrd</code> in its array argument <i>tauq</i> or <i>taup</i>. <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) COMPLEX for <code>pcunmbr</code> DOUBLE COMPLEX for <code>pzunmbr</code> Pointer into the local memory to an array of dimension $(lld\_a, LOCc(jc+n-1))$.

<i>ic, jc</i>	Contains the local pieces of the distributed matrix sub (<i>c</i>). (global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <i>c</i> , respectively.
<i>desc</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) COMPLEX for pcunmbr DOUBLE COMPLEX for pzunmbr. Workspace array of dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER, dimension of <i>work</i> , must be at least: If <i>side</i> = 'L' <i>nq</i> = <i>m</i> ; if ((<i>vect</i> = 'Q' and <i>nq</i> ≥ <i>k</i>) or (<i>vect</i> is not equal to 'Q' and <i>nq</i> > <i>k</i>)), <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> ; <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> ; else <i>iaa</i> = <i>ia</i> +1; <i>jaa</i> = <i>ja</i> ; <i>mi</i> = <i>m</i> -1; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> +1; <i>jcc</i> = <i>jc</i> ; end if else If <i>side</i> = 'R', <i>nq</i> = <i>n</i> ; if ((<i>vect</i> = 'Q' and <i>nq</i> ≥ <i>k</i>) or (<i>vect</i> is not equal to 'Q' and <i>nq</i> ≥ <i>k</i>)), <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> ; <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> ; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> ; else <i>iaa</i> = <i>ia</i> ; <i>jaa</i> = <i>ja</i> +1; <i>mi</i> = <i>m</i> ; <i>ni</i> = <i>n</i> -1; <i>icc</i> = <i>ic</i> ; <i>jcc</i> = <i>jc</i> +1; end if end if If <i>vect</i> = 'Q', If <i>side</i> = 'L', <i>lwork</i> ≥ max((<i>nb_a</i> *(<i>nb_a</i> -1))/2, (<i>nqc</i> 0+ <i>mpc</i> 0)* <i>nb_a</i>) + <i>nb_a</i> * <i>nb_a</i> else if <i>side</i> = 'R',

mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow,
NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol,
NPCOL),
indxg2p and numroc are ScaLAPACK tool functions; MYROW,
MYCOL, NPROW and NPCOL can be determined by calling the
subroutine blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c	On exit, if $vect='Q'$, $sub(c)$ is overwritten by $Q*sub(C)$, or $Q'*sub(C)$, or $sub(C)*Q'$, or $sub(C)*Q$; if $vect='P'$, $sub(c)$ is overwritten by $P*sub(C)$, or $P'*sub(C)$, or $sub(C)*P$, or $sub(C)*P'$.
$work(1)$	On exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Generalized Symmetric-Definite Eigen Problems

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see [Generalized Symmetric-Definite Eigenvalue Problems](#) in LAPACK chapters) to standard symmetric eigenvalue problem $C_Y = \lambda_Y$, which you can solve by calling ScaLAPACK routines described earlier in this chapter (see [Symmetric Eigenproblems](#)).

[Table 6-7](#) lists these routines.

Table 6-7 Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	p?sygst	p?hegst

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pssygst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info )

call pdsygst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info )
```

Description

This routine reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x,$$

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x,$$

and $\text{sub}(A)$ is overwritten by $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$.

$\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L * L^T$ by p?potrf.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. If $itype = 1$, compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$; If $itype = 2$ or 3 , compute $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. If $uplo = 'U'$, the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^T * U$.

	If $uplo = 'L'$, the lower triangle of $sub(A)$ is stored and $sub(B)$ is factored as $L * L^T$.
n	(global) INTEGER. The order of the matrices $sub(A)$ and $sub(B)$ ($n \geq 0$).
a	(local) REAL for pssygst DOUBLE PRECISION for pdsygst. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+n-1))$. On entry, the array contains the local pieces of the n-by-n symmetric distributed matrix $sub(A)$. If $uplo = 'U'$, the leading n-by-n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n-by-n lower triangular part of $sub(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A, respectively.
$desca$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A.
b	(local) REAL for pssygst DOUBLE PRECISION for pdsygst. Pointer into the local memory to an array of dimension $(lld\_b, LOCC(jb+n-1))$. On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $sub(B)$ as returned by p?potrf.
ib, jb	(global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B, respectively.
$descb$	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix B.

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) REAL for pssygst DOUBLE PRECISION for pdsygst. Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?hegst

Reduces a Hermitian-definite generalized eigenvalue problem to the standard form.

Syntax

```
call pchegst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info)

call pzhegst( ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, scale,
info)
```

Description

This routine reduces complex Hermitian-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes *A*(*ia:ia*+*n*-1, *ja:ja*+*n*-1) and sub(*B*) denotes *B*(*ib:ib*+*n*-1, *jb:jb*+*n*-1).

If *ibtype* = 1, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x,$$

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$.

If $\text{ibtype} = 2$ or 3 , the problem is

$\text{sub}(A) * \text{sub}(B) * x = \lambda * x$, or $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$,

and $\text{sub}(A)$ is overwritten by $U * \text{sub}(A) * U^H$, or $L^H * \text{sub}(A) * L$.

$\text{sub}(B)$ must have been previously factorized as $U^H * U$ or $L * L^H$ by `p?potrf`.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. If $\text{itype} = 1$, compute $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$; If $\text{itype} = 2$ or 3 , compute $U * \text{sub}(A) * U^H$, or $L^H * \text{sub}(A) * L$.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. If $\text{uplo} = 'U'$, the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $U^H * U$. If $\text{uplo} = 'L'$, the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L * L^H$.
<i>n</i>	(global) INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) COMPLEX for <code>pchegst</code> DOUBLE COMPLEX for <code>pzhgst</code> . Pointer into the local memory to an array of dimension $(\text{lld\_a}, \text{LOC}(ja+n-1))$. On entry, the array contains the local pieces of the n -by- n Hermitian distributed matrix $\text{sub}(A)$. If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for <i>pchegst</i> DOUBLE COMPLEX for <i>pzhegst</i> . Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb+n-1)</i>). On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (<i>B</i>) as returned by <i>p?potrf</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) REAL for <i>pchegst</i> DOUBLE PRECISION for <i>pzhegst</i> . Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this routine. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> 100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Driver Routines

Table 6-8 lists ScaLAPACK driver routines available for solving systems of linear equations, linear least-squares problems, standard eigenvalue and singular value problems, and generalized symmetric definite eigenproblems.

Table 6-8 ScaLAPACK Driver Routines

Type of Problem	Matrix type, storage scheme	Driver
Linear equations	general (partial pivoting)	p?gesv (simple driver) p?gesvx (expert driver)
	general band (partial pivoting)	p?gbsv (simple driver)
	general band (no pivoting)	p?dbsv (simple driver)
	general tridiagonal (no pivoting)	p?dtsv (simple driver)
	symmetric/Hermitian positive-definite	p?posv (simple driver) p?posvx (expert driver)
	symmetric/Hermitian positive-definite, band	p?pbsv (simple driver)
	symmetric/Hermitian positive-definite, tridiagonal	p?ptsv (simple driver)
Linear least squares problem	general m -by- n	p?gels
Symmetric eigenvalue problem	symmetric/Hermitian	p?syev (simple driver) p?syevx / p?heevx (expert driver)
Singular value decomposition	general m -by- n	p?gesvd
Generalized symmetric definite eigenvalue problem	symmetric/Hermitian, one matrix also positive-definite	p?sygvx / p?hegvx (expert driver)

p?gesv

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

```
call psgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pdgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pcgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
call pzgesv(n, nrhs, a, ia, ja, desca, ipiv, b, ib, jb, descb, info)
```

Description

The routine `p?gesv` computes the solution to a real or complex system of linear equations $\text{sub}(A) * X = \text{sub}(B)$, where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is an n -by- n distributed matrix and X and $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. L and U are stored in $\text{sub}(A)$. The factored form of $\text{sub}(A)$ is then used to solve the system of equations $\text{sub}(A) * X = \text{sub}(B)$.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
$nrhs$	(global) INTEGER. The number of right hand sides, that is, the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).
a, b	(local) REAL for <code>psgesv</code> DOUBLE PRECISION for <code>pdgesv</code> COMPLEX for <code>pcgesv</code> DOUBLE COMPLEX for <code>pzgesv</code> . Pointers into the local memory to arrays of local dimension $a(\text{lld\_a}, \text{LOCc}(\text{ja}+n-1))$ and $b(\text{lld\_b}, \text{LOCc}(\text{jb}+nrhs-1))$, respectively. On entry, the array a contains the local pieces of the n -by- n distributed matrix $\text{sub}(A)$ to be factored. On entry, the array b contains the right hand side distributed matrix $\text{sub}(B)$.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array, dimension (dlen_) . The array descriptor for the distributed matrix A .

<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	Overwritten by the factors <i>L</i> and <i>U</i> from the factorization $\text{sub}(A) = P^*L^*U$; the unit diagonal elements of <i>L</i> are not stored .
<i>b</i>	Overwritten by the solution distributed matrix <i>x</i> .
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> is $(\text{LOCr}(m\_a) + mb\_a)$. This array contains the pivoting information. The (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv(i)</i> . This array is tied to the distributed matrix <i>A</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. <i>info</i> > 0: If <i>info</i> = <i>k</i> , $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution could not be computed.

p?gesvx

Uses the LU factorization to compute the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

```
call psgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, iwork, liwork, info)
```

```
call pdgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, iwork, liwork, info)
```

```
call pcgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, rwork, lrwork, info)
```

```
call pzgesvx(fact, trans, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
            ipiv, equed, r, c, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr,
            work, lwork, rwork, lrwork, info)
```

Description

This routine uses the LU factorization to compute the solution to a real or complex system of linear equations $AX = B$, where A denotes the n -by- n submatrix $A(ia:ia+n-1, ja:ja+n-1)$, B denotes the n -by- $nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and X denotes the n -by- $nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, af stands for the subarray $af(iaf:iaf+n-1, jaf:jaf+n-1)$.

The routine p?gesvx performs the following steps:

1. If $fact = 'E'$, real scaling factors R and C are computed to equilibrate the system:

$$trans = 'N': \text{diag}(R) * A * \text{diag}(C) * \text{diag}(C)^{-1} * X = \text{diag}(R) * B$$

$$trans = 'T': (\text{diag}(R) * A * \text{diag}(C))^T * \text{diag}(R)^{-1} * X = \text{diag}(C) * B$$

$$trans = 'C': (\text{diag}(R) * A * \text{diag}(C))^H * \text{diag}(R)^{-1} * X = \text{diag}(C) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if $\text{trans} = 'N'$) or $\text{diag}(C) * B$ (if $\text{trans} = 'T'$ or $'C'$).

2. If $\text{fact} = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $\text{fact} = 'E'$) as $A = P L U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $\text{trans} = 'N'$) or $\text{diag}(R)$ (if $\text{trans} = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

fact (global) CHARACTER*1. Must be 'F', 'N', or 'E'.
 Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
 If $\text{fact} = 'F'$ then, on entry, af and $ipiv$ contain the factored form of A . If equed is not 'N', the matrix A has been equilibrated with scaling factors given by r and c . Arrays a , af , and $ipiv$ are not modified.
 If $\text{fact} = 'N'$, the matrix A is copied to af and factored.
 If $\text{fact} = 'E'$, the matrix A is equilibrated if necessary, then copied to af and factored.

trans (global) CHARACTER*1. Must be 'N', 'T', or 'C'.
 Specifies the form of the system of equations:
 If $\text{trans} = 'N'$, the system has the form $A * X = B$ (No transpose);
 If $\text{trans} = 'T'$, the system has the form $A^T * X = B$ (Transpose);
 If $\text{trans} = 'C'$, the system has the form $A^H * X = B$ (Conjugate transpose);

<i>n</i>	(global) INTEGER. The number of linear equations; the order of the submatrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrices <i>B</i> and <i>X</i> ($nrhs \geq 0$).
<i>a, af, b, work</i>	(local) REAL for psgesvx DOUBLE PRECISION for pdgesvx COMPLEX for pcgesvx DOUBLE COMPLEX for pzgesvx. Pointers into the local memory to arrays of local dimension <i>a</i>(<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)), <i>af</i>(<i>lld_af</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)), <i>b</i>(<i>lld_b</i>, <i>LOCc</i>(<i>jb</i>+<i>nrhs</i>-1)), <i>work</i>(<i>lwork</i>), respectively. The array <i>a</i> contains the matrix <i>A</i>. If <i>fact</i> = 'F' and <i>equed</i> is not 'N', then <i>A</i> must have been equilibrated by the scaling factors in <i>r</i> and/or <i>c</i>. The array <i>af</i> is an input argument if <i>fact</i> = 'F'. In this case it contains on entry the factored form of the matrix <i>A</i>, that is, the factors <i>L</i> and <i>U</i> from the factorization $A = P^*L^*U$ as computed by p?getrf. If <i>equed</i> is not 'N', then <i>af</i> is the factored form of the equilibrated matrix <i>A</i>. The array <i>b</i> contains on entry the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. <i>work</i>(*) is a workspace array. The dimension of <i>work</i> is (<i>lwork</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> (<i>ia</i> : <i>ia</i> + <i>n</i> -1, <i>ja</i> : <i>ja</i> + <i>n</i> -1), respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) INTEGER. The row and column indices in the global array <i>af</i> indicating the first row and the first column of the subarray <i>af</i> (<i>iaf</i> : <i>iaf</i> + <i>n</i> -1, <i>jaf</i> : <i>jaf</i> + <i>n</i> -1), respectively.
<i>descaf</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>AF</i> .

<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the submatrix <i>B(ib:ib+n-1, jb:jb+nrhs-1)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>ipiv</i>	(local) INTEGER array. The dimension of <i>ipiv</i> is $LOCr(m\_a) + mb\_a$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. On entry, it contains the pivot indices from the factorization $A = P * L * U$ as computed by <i>p?getrf</i> ; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv(i)</i> . This array must be aligned with <i>A(ia:ia+n-1, *)</i> .
<i>equed</i>	(global) CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag(r)</i> ; If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag(c)</i> ; If <i>equed</i> = 'B', both row and column equilibration was done; <i>A</i> has been replaced by <i>diag(r) * A * diag(c)</i> .
<i>r, c</i>	(local) REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Arrays, dimension $LOCr(m\_a)$ and $LOCc(n\_a)$, respectively. The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag(r)</i> ; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag(c)</i> ; if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive. Array *r* is replicated in every process column, and is aligned with the distributed matrix *A*. Array *c* is replicated in every process row, and is aligned with the distributed matrix *A*.

<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix <i>X(ix:ix+n-1, jx:jx+nrhs-1)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> ; must be at least $\max(\text{p?gecon}(\text{lwork}), \text{p?gerfs}(\text{lwork})) + \text{LOCr}(\text{n\_a})$.
<i>iwork</i>	(local, psgesvx/pdgesvx only) INTEGER. Workspace array. The dimension of <i>iwork</i> is (<i>liwork</i>).
<i>liwork</i>	(local, psgesvx/pdgesvx only) INTEGER. The dimension of the array <i>iwork</i> , must be at least $\text{LOCr}(\text{n\_a})$.
<i>rwork</i>	(local) REAL for pcgesvx DOUBLE PRECISION for pzgesvx. Workspace array, used in complex flavors only. The dimension of <i>rwork</i> is (<i>lrwork</i>).
<i>lrwork</i>	(local or global, pcgesvx/pzgesvx only) INTEGER. The dimension of the array <i>rwork</i> ; must be at least $2 * \text{LOCc}(\text{n\_a})$.

Output Parameters

<i>x</i>	(local) REAL for psgesvx DOUBLE PRECISION for pdgesvx COMPLEX for pcgesvx DOUBLE COMPLEX for pzgesvx. Pointer into the local memory to an array of local dimension $x(\text{lld\_x}, \text{LOCc}(\text{jx} + \text{nrhs} - 1))$.

	If $info = 0$, the array x contains the solution matrix X to the <i>original</i> system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the <i>equilibrated</i> system is: $diag(C)^{-1} * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; and $diag(R)^{-1} * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$.
a	Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$. If $equed \neq 'N'$, A is scaled on exit as follows: $equed = 'R'$: $A = diag(R) * A$ $equed = 'C'$: $A = A * diag(c)$ $equed = 'B'$: $A = diag(R) * A * diag(c)$
af	If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.
b	Overwritten by $diag(R) * B$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$; overwritten by $diag(c) * B$ if $trans = 'T'$ and $equed = 'C'$ or $'B'$; not changed if $equed = 'N'$.
r, c	These arrays are output arguments if $fact \neq 'F'$. See the description of r, c in <i>Input Arguments</i> section.
$rcond$	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A after equilibration (if done). The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
$ferr, berr$	(local) REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

	Arrays, DIMENSION $LOCc(n\_b)$ each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector. Arrays <i>ferr</i> and <i>berr</i> are both replicated in every process row, and are aligned with the matrices <i>B</i> and <i>X</i> .
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F' , then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) returns the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> (1)	If <i>info</i> =0, on exit <i>iwork</i> (1) returns the minimum value of <i>liwork</i> required for optimum performance.
<i>rwork</i> (1)	If <i>info</i> =0, on exit <i>rwork</i> (1) returns the minimum value of <i>lrwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. If <i>info</i> = <i>i</i> , and $i \leq n$, then $U(i,i)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution and error bounds could not be computed. If <i>info</i> = <i>i</i> , and $i = n + 1$, then <i>U</i> is nonsingular, but <i>rcond</i> is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

p?gbsv

Computes the solution to the system of linear equations with a general banded distributed matrix and multiple right-hand sides.

Syntax

```
call psgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork,
info)

call pdgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork,
info)

call pcgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork,
info)

call pzgbsv(n, bwl, bwu, nrhs, a, ja, desca, ipiv, b, ib, descb, work, lwork,
info)
```

Description

The routine p?gbsv computes the solution to a real or complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real/complex general banded distributed matrix with bwl subdiagonals and bwu superdiagonals, and X and $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U * Q$, where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
bwl	(global) INTEGER. The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$).

<i>bwu</i>	(global) INTEGER. The number of superdiagonals within the band of <i>A</i> ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix <i>sub(B)</i> ($nrhs \geq 0$).
<i>a, b</i>	(local) REAL for psgbsv DOUBLE PRECISION for pdgbsv COMPLEX for pcgbsv DOUBLE COMPLEX for pzgbsv. Pointers into the local memory to arrays of local dimension <i>a(lld_a, LOCC(ja+n-1))</i> and <i>b(lld_b, LOCC(nrhs))</i> , respectively. On entry, the array <i>a</i> contains the local pieces of the global array <i>A</i> . On entry, the array <i>b</i> contains the right hand side distributed matrix <i>sub(B)</i> .
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(dtype_)</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>desca(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . If <i>descb(dtype_)</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>descb(dtype_)</i> = 1, then <i>dlen_</i> ≥ 9.
<i>work</i>	(local) REAL for psgbsv DOUBLE PRECISION for pdgbsv COMPLEX for pcgbsv

DOUBLE COMPLEX for pzgbsv.
 Workspace array of dimension (*lwork*).
lwork (local or global) INTEGER. The size of the array *work*, must be at least $lwork \geq (NB+bwu) * (bwl+bwu) + 6 * (bwl+bwu) * (bwl+2 * bwu) + \max(nrhs * (NB+2 * bwl+4 * bwu), 1)$.

Output Parameters

a On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

b On exit, this array contains the local pieces of the solution distributed matrix *x*.

ipiv (local) INTEGER array.
 The dimension of *ipiv* must be at least *desca*(NB). This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.

work(1) On exit, *work*(1) contains the minimum value of *lwork* required for optimum performance.

info INTEGER. If *info*=0, the execution is successful. *info* < 0:
 If the *i*th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*th argument is a scalar and had an illegal value, then *info* = -*i*.
info > 0:
 If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not nonsingular, and the factorization was not completed. If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?dbsv

Solves a general band system of linear equations.

Syntax

```
call psdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pddbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzdbsv(n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Description

This routine solves the system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded diagonally dominant-like distributed matrix with bandwidth bwl, bwu .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix A , ($n \geq 0$).
bwl	(global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.
bwu	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
$nrhs$	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B , ($nrhs \geq 0$).
a	(local). REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv.

	Pointer into the local memory to an array with first dimension $lld\_a \geq (bwl+bwu+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen</i>. If 1d type (<i>dtype_a</i>=501 or 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_a</i>=1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i>. Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv. Pointer into the local memory to an array of local lead dimension $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i>. If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i>. Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). REAL for psdbsv DOUBLE PRECISION for pddbsv COMPLEX for pcdbsv DOUBLE COMPLEX for pzdbsv.

Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork

(local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

$lwork \geq$

$nb(bwl+bwu) + 6 \max(bwl, bwu) * \max(bwl, bwu) + \max(\max(bwl, bwu) nrhs, \max(bwl, bwu) * \max(bwl, bwu))$

Output Parameters

a

On exit, this array contains information containing details of the factorization.

Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

b

On exit, this contains the local piece of the solutions distributed matrix *x*.

work

On exit, *work*(1) contains the minimal *lwork*.

info

(local) INTEGER. If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

> 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?dtsv

Solves a general tridiagonal system of linear equations.

Syntax

```
call psdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pddtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pcdtsv(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
call pzdtvs(n, nrhs, dl, d, du, ja, desca, b, ib, descb, work, lwork, info)
```

Description

This routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into $L U$.

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix A ($n \geq 0$).
$nrhs$	INTEGER. The number of right hand sides; the number of columns of the distributed matrix B ($nrhs \geq 0$).
dl	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtvs. Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $dl(1)$ is not referenced, and dl must be aligned with d . Must be of size $> desca(nb\_)$.
d	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv

	DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i> (<i>n</i>) is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_a</i> =501 or 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_a</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdtsv DOUBLE PRECISION for pddtsv COMPLEX for pcdtsv DOUBLE COMPLEX for pzdtsv. Pointer into the local memory to an array of local lead dimension <i>lld_b</i> > <i>nb</i> . On entry, this array contains the local pieces of the right hand sides <i>B</i> (<i>ib:ib+n-1</i> , 1: <i>nrhs</i>).
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_b</i> =502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local).

REAL for psdtsv
 DOUBLE PRECISION for pddtsv
 COMPLEX for pcdtsv
 DOUBLE COMPLEX for pzdtstv. Temporary workspace. This space may be overwritten in between calls to routines. *work* must be the size given in *lwork*.

lwork (local or global) INTEGER. Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned. *lwork* > (12*NPCOL+3*nb)+max((10+2*min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL)

Output Parameters

dl On exit, this array contains information containing the * factors of the matrix.

d On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*(*nb_*).

du On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*(*nb_*).

b On exit, this contains the local piece of the solutions distributed matrix *X*.

work On exit, *work*(1) contains the minimal *lwork*.

info (local) INTEGER. If *info*=0, the execution is successful.
 < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
 > 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
 If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

p?posv

Solves a symmetric positive definite system of linear equations.

Syntax

```
call psposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pdposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pcposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
call pzposv(uplo, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

This routine computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and is an n -by- n symmetric/Hermitian distributed positive definite matrix and X and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices. The Cholesky decomposition is used to factor $\text{sub}(A)$ as

$$\text{sub}(A) = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of $\text{sub}(A)$ is then used to solve the system of equations.

Input Parameters

<i>uplo</i>	(global). CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a</i>	(local) REAL for psposv DOUBLE PRECISION for pdposv

	COMPLEX for pcpovs COMPLEX*16 for pzposv. Pointer into the local memory to an array of dimension $(lld\_a, LOC(ja+n-1))$. On entry, this array contains the local pieces of the n-by-n symmetric distributed matrix $\text{sub}(A)$ to be factored. If $uplo = 'U'$, the leading n-by-n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n-by-n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for pspovs DOUBLE PRECISION for pdposv COMPLEX for pcpovs COMPLEX*16 for pzposv. Pointer into the local memory to an array of dimension $(lld\_b, LOC(jb+nrhs-1))$. On entry, the local pieces of the right hand sides distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if $info = 0$, this array contains the local pieces of the factor <i>U</i> or <i>L</i> from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $L * L^H$.

<i>b</i>	On exit, if <i>info</i> = 0, sub(<i>B</i>) is overwritten by the solution distributed matrix <i>X</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = <i>k</i> , the leading minor of order <i>k</i> , <i>A</i> (<i>ia:ia+k-1, ja:ja+k-1</i>) is not positive definite, and the factorization could not be completed, and the solution has not been computed.

p?posvx

Solves a symmetric or Hermitian positive definite system of linear equations.

Syntax

```
call psposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

```
call pdposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

```
call pcposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

```
call pzposvx(fact, uplo, n, nrhs, a, ia, ja, desca, af, iaf, jaf, descaf,
equed, sr, sc, b, ib, jb, descb, x, ix, jx, descx, rcond, ferr, berr, work,
lwork, iwork, liwork, info)
```

Description

This routine uses the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ to compute the solution to a real or complex system of linear equations

$$A(ia:ia+n-1, ja:ja+n-1)*X = B(ib:ib+n-1, jb:jb+nrhs-1),$$

where $A(ia:ia+n-1, ja:ja+n-1)$ is a n -by- n matrix and X and $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments y denotes $Y(iy:iy+m-1, jy:jy+k-1)$ a m -by- k matrix where y can be a, af, b and x .

The routine `p?posvx` performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$$\text{diag}(sr) * A * \text{diag}(sc) * \text{inv}(\text{diag}(sc)) * X = \text{diag}(sr) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(sr) * A * \text{diag}(sc)$ and B by $\text{diag}(sr) * B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$$A = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$A = L * L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for x using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix x is premultiplied by $\text{diag}(sr)$ so that it solves the original system before equilibration.

Input Parameters

fact (global) CHARACTER. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
If $fact = 'F'$: on entry, af contains the factored form of A . If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s . a and af will not be modified.

	If <i>fact</i> = 'N', the matrix <i>A</i> will be copied to <i>af</i> and factored. If <i>fact</i> = 'E', the matrix <i>A</i> will be equilibrated if necessary, then copied to <i>af</i> and factored.
<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix <i>sub(A)</i> ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrices <i>B</i> and <i>X</i>. ($nrhs \geq 0$).
<i>a</i>	(local) REAL for <i>psposvx</i> DOUBLE PRECISION for <i>pdposvx</i> COMPLEX for <i>pcposvx</i> DOUBLE COMPLEX for <i>pzposvx</i>. Pointer into the local memory to an array of local dimension (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, the symmetric/Hermitian matrix <i>A</i>, except if <i>fact</i> = 'F' and <i>equed</i> = 'Y', then <i>A</i> must contain the equilibrated matrix <i>diag(sr)*A*diag(sc)</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>A</i> contains the upper triangular part of the matrix <i>A</i>, and the strictly lower triangular part of <i>A</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>A</i> contains the lower triangular part of the matrix <i>A</i>, and the strictly upper triangular part of <i>A</i> is not referenced. <i>A</i> is not modified if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N' on exit.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>af</i>	(local)

REAL for psposvx
 DOUBLE PRECISION for pdposvx
 COMPLEX for pcposvx
 DOUBLE COMPLEX for pzposvx.
 Pointer into the local memory to an array of local dimension
 (lld_af , $LOCc(ja+n-1)$).
 If $fact = 'F'$, then af is an input argument and on entry
 contains the triangular factor U or L from the Cholesky
 factorization $A = U^T * U$ or $A = L * L^T$, in the same storage
 format as A . If $equed \neq 'N'$, then af is the factored form
 of the equilibrated matrix $diag(sr) * A * diag(sc)$.
iaf, jaf (global) INTEGER. The row and column indices in the global
 array af indicating the first row and the first column of the
 submatrix AF , respectively.
descaf (global and local) INTEGER array, dimension ($dlen\_$). The
 array descriptor for the distributed matrix AF .
equed (global). CHARACTER. Must be 'N' or 'Y'.
equed is an input argument if $fact = 'F'$. It specifies the
 form of equilibration that was done:
 If $equed = 'N'$, no equilibration was done (always true if
 $fact = 'N'$);
 If $equed = 'Y'$, equilibration was done and A has been
 replaced by $diag(sr) * A * diag(sc)$.
sr (local)
 REAL for psposvx
 DOUBLE PRECISION for pdposvx
 COMPLEX for pcposvx
 DOUBLE COMPLEX for pzposvx.
 Array, DIMENSION (lld_a).
 The array s contains the scale factors for A . This array is an
 input argument if $fact = 'F'$ only; otherwise it is an output
 argument.
 If $equed = 'N'$, s is not accessed.
 If $fact = 'F'$ and $equed = 'Y'$, each element of s must
 be positive.
b (local)
 REAL for psposvx

	DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. Pointer into the local memory to an array of local dimension $(lld\_b, LOCc(jb+nrhs-1))$. On entry, the n -by- $nrhs$ right-hand side matrix B .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.
<i>descb</i>	(global and local) INTEGER. Array, dimension $(dlen\_)$. The array descriptor for the distributed matrix B .
<i>x</i>	(local) REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. Pointer into the local memory to an array of local dimension $(lld\_x, LOCc(jx+nrhs-1))$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array x indicating the first row and the first column of the submatrix x , respectively.
<i>descx</i>	(global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix x .
<i>work</i>	(local) REAL for psposvx DOUBLE PRECISION for pdposvx COMPLEX for pcposvx DOUBLE COMPLEX for pzposvx. Workspace array, DIMENSION $(lwork)$.
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork = \max(p?pocon(lwork), p?porfs(lwork)) + LOCr(n\_a)$. $lwork = 3*desca(lld\_)$.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

iwork

(local) INTEGER. Workspace array, dimension ($liwork$).

liwork

(local or global)

INTEGER. The dimension of the array *iwork*. *liwork* is local input and must be at least $liwork = desca(lld\_)$ $liwork = LOCr(n\_a)$.

If $liwork = -1$, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, if $fact = 'E'$ and $equed = 'Y'$, *a* is overwritten by $diag(sr) * a * diag(sc)$.

af

If $fact = 'N'$, then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix *A*.

If $fact = 'E'$, then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the equilibrated matrix *A* (see the description of *A* for the form of the equilibrated matrix).

equed

If $fact \neq 'F'$, then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

sr

This array is an output argument if $fact \neq 'F'$. See the description of *sr* in *Input Arguments* section.

sc

This array is an output argument if $fact \neq 'F'$.

	See the description of <i>sc</i> in <i>Input Arguments</i> section.
<i>b</i>	On exit, if <i>equed</i> = 'N', <i>b</i> is not modified; if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B', <i>b</i> is overwritten by $\text{diag}(r) * b$; if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B', <i>b</i> is overwritten by $\text{diag}(c) * b$.
<i>x</i>	(local) REAL for <i>psposvx</i> DOUBLE PRECISION for <i>pdposvx</i> COMPLEX for <i>pcposvx</i> DOUBLE COMPLEX for <i>pzposvx</i> . If <i>info</i> = 0 the <i>n</i> -by- <i>nrhs</i> solution matrix <i>x</i> to the original system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(sc)) * X$ if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B', or $\text{inv}(\text{diag}(sr)) * X$ if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'.
<i>rcond</i>	(global) REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> =0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(LOC, n\_b)$. The estimated forward error bounds for each solution vector <i>x</i> (<i>j</i>) (the <i>j</i> -th column of the solution matrix <i>x</i>). If <i>xtrue</i> is the true solution, <i>ferr</i> (<i>j</i>) bounds the magnitude of the largest entry in $(X(j) - xtrue)$ divided by the magnitude of the largest entry in <i>x</i> (<i>j</i>). The quality of the error bound depends on the quality of the estimate of $\text{norm}(\text{inv}(A))$ computed in the code; if the estimate of $\text{norm}(\text{inv}(A))$ is accurate, the error bound is guaranteed.

berr (local)
 REAL for single precision flavors.
 DOUBLE PRECISION for double precision flavors.
 Arrays, DIMENSION at least $\max(LOC, n\_b)$. The componentwise relative backward error of each solution vector $x(j)$ (the smallest relative change in any entry of A or B that makes $x(j)$ an exact solution).

work(1) (local) On exit, *work(1)* returns the minimal and optimal *liwork*.

info (global) INTEGER.
 If *info*=0, the execution is successful.
 < 0: if *info* = -*i*, the *i*-th argument had an illegal value
 > 0: if *info* = *i*, and *i* is ≤ *n*: if *info* = *i*, the leading minor of order *i* of *a* is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.
 = *n*+1: *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

p?pbsv

Solves a symmetric/Hermitian positive definite banded system of linear equations.

Syntax

```
call pspbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pdpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pcpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
call pzpbsv(uplo, n, bw, nrhs, a, ja, desca, b, ib, descb, work, lwork, info)
```

Description

This routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded symmetric positive definite distributed matrix with bandwidth bw .

Cholesky factorization is used to factor a reordering of the matrix into L^*L' .

Input Parameters

<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. Indicates whether the upper or lower triangular of A is stored. If <i>uplo</i> = 'U', the upper triangular A is stored If <i>uplo</i> = 'L', the lower triangular of A is stored.
<i>n</i>	(global) INTEGER. The order of the distributed matrix A ($n \geq 0$).
<i>bw</i>	(global) INTEGER. The number of subdiagonals in L or U . $0 \leq bw \leq n-1$.
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a</i>	(local). REAL for pspbsv DOUBLE PRECISION for pdpbsv COMPLEX for pcpbsv DOUBLE COMPLEX for pzpbsv. Pointer into the local memory to an array with first dimension $lld\_a \geq (bw+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix $sub(A)$ to be factored.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix A .
<i>b</i>	(local) REAL for pspbsv DOUBLE PRECISION for pdpbsv COMPLEX for pcpbsv DOUBLE COMPLEX for pzpbsv.

	Pointer into the local memory to an array of local lead dimension $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1D type (<i>dtype_b</i> = 502), $dlen \geq 7$; If 2D type (<i>dtype_b</i> = 1), $dlen \geq 9$. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). REAL for pspbsv DOUBLE PRECISION for pdpbsv COMPLEX for pcpbsv DOUBLE COMPLEX for pzpbsv. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned. $lwork \geq (nb+2*bw)*bw + \max(bw*nrhs, bw*bw)$

Output Parameters

<i>a</i>	On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>b</i>	On exit, contains the local piece of the solutions distributed matrix <i>x</i> .
<i>work</i>	On exit, <i>work</i> (1) contains the minimal <i>lwork</i> .
<i>info</i>	(global). INTEGER. If <i>info</i> =0, the execution is successful.

< 0: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0: If $info = k \leq \text{NPROCS}$, the submatrix stored on processor $info$ and factored locally was not positive definite, and the factorization was not completed.

If $info = k > \text{NPROCS}$, the submatrix stored on processor $info - \text{NPROCS}$ representing interactions with other processors was not positive definite, and the factorization was not completed.

p?ptsv

Solves a symmetric or Hermitian positive definite tridiagonal system of linear equations.

Syntax

```
call psptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pdptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pcptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
call pzptsv(n, nrhs, d, e, ja, desca, b, ib, descb, work, lwork, info)
```

Description

This routine solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real tridiagonal symmetric positive definite distributed matrix.

Cholesky factorization is used to factor a reordering of the matrix into $L * L'$.

Input Parameters

n (global) INTEGER. The order of matrix A ($n \geq 0$).

<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix <i>B</i> (<i>nrhs</i> ≥ 0).
<i>d</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer to local part of global vector storing the main diagonal of the matrix.
<i>e</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i> (<i>n</i>) is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1 <i>d</i> type (<i>dtype_a</i> =501 or 502), <i>dlen</i> ≥ 7; If 2 <i>d</i> type (<i>dtype_a</i> =1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Pointer into the local memory to an array of local lead dimension <i>lld_b</i> ≥ <i>nb</i> . On entry, this array contains the local pieces of the right hand sides <i>B</i> (<i>ib</i> : <i>ib</i> + <i>n</i> -1, 1: <i>nrhs</i>).

<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of dimension <i>dlen</i> . If 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping of <i>B</i> to memory.
<i>work</i>	(local). REAL for psptsv DOUBLE PRECISION for pdptsv COMPLEX for pcptsv DOUBLE COMPLEX for pzptsv. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> (1) and an error code is returned. <i>lwork</i> > (12*NPCOL+3*nb)+max((10+2*min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL).

Output Parameters

<i>d</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> (<i>nb_</i>).
<i>e</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> (<i>nb_</i>).
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix <i>x</i> .
<i>work</i>	On exit, <i>work</i> (1) contains the minimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. If <i>info</i> =0, the execution is successful.

< 0 : If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

> 0 : If $info = k \leq NPROCS$, the submatrix stored on processor $info$ and factored locally was not positive definite, and the factorization was not completed.

If $info = k > NPROCS$, the submatrix stored on processor $info-NPROCS$ representing interactions with other processors was not positive definite, and the factorization was not completed.

p?gels

Solves overdetermined or underdetermined linear systems involving a matrix of full rank.

Syntax

```
call psgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```
call pdgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```
call pcgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

```
call pzgels(trans, m, n, nrhs, a, ia, ja, desca, b, ib, jb, descb, work, lwork, info)
```

Description

This routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, or its transpose/ conjugate-transpose, using a QTQ or LQ factorization of $\text{sub}(A)$. It is assumed that $\text{sub}(A)$ has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

```
minimize ||sub(B) - sub(A)*X||
```

2. If $trans = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system
 $sub(A) * X = sub(B)$.
3. If $trans = 'T'$ and $m \geq n$: find the minimum norm solution of an undetermined system
 $sub(A)^T * X = sub(B)$.
4. If $trans = 'T'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem
 $minimize ||sub(B) - sub(A)^T * X||,$
 where $sub(B)$ denotes $B(ib:ib+m-1, jb:jb+nrhs-1)$ when $trans = 'N'$ and $B(ib:ib+n-1, jb:jb+nrhs-1)$ otherwise. Several right hand side vectors b and solution vectors x can be handled in a single call; when $trans = 'N'$, the solution vectors are stored as the columns of the n -by- $nrhs$ right hand side matrix $sub(B)$ and the m -by- $nrhs$ right hand side matrix $sub(B)$ otherwise.

Input Parameters

<i>trans</i>	(global) CHARACTER. Must be 'N', or 'T'. If $trans = 'N'$, the linear system involves matrix $sub(A)$; If $trans = 'T'$, the linear system involves the transposed matrix A^T (for real flavors only).
<i>m</i>	(global) INTEGER. The number of rows in the distributed submatrix $sub(A)$ ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns in the distributed submatrix $sub(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns in the distributed submatrices $sub(B)$ and X . ($nrhs \geq 0$).
<i>a</i>	(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels. Pointer into the local memory to an array of dimension $(lld\_a, LOCC(ja+n-1))$. On entry, contains the m -by- n matrix A .

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels. Pointer into the local memory to an array of local dimension (<i>lld_b</i> , <i>LOCc(jb+nrhs-1)</i>). On entry, this array contains the local pieces of the distributed matrix <i>B</i> of right-hand side vectors, stored columnwise; sub(<i>B</i>) is <i>m</i> -by- <i>nrhs</i> if <i>trans</i> ='N', and <i>n</i> -by- <i>nrhs</i> otherwise.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) REAL for psgels DOUBLE PRECISION for pdgels COMPLEX for pcgels DOUBLE COMPLEX for pzgels. Workspace array with dimension <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> <i>lwork</i> is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then $ltau = \text{numroc}(ja + \min(m, n) - 1, nb\_a, MYCOL, csrc\_a, NPCOL),$ $lwf = nb\_a * (mpa0 + nqa0 + nb\_a)$ $lws = \max((nb\_a * (nb\_a - 1)) / 2, (nrhsqb0 + mpb0) * nb\_a) + nb\_a * nb\_a$ else

```

ltau = numroc(ia+min(m,n)-1, mb_a, MYROW,
rsrc_a, NPROW),
lwf = mb_a * (mpa0 + nqa0 + mb_a)
lws = max((mb_a*(mb_a-1))/2, (npb0 + max(nqa0 +
numroc(numroc(n+iroffb, mb_a, 0, 0, NPROW),
mb_a, 0, 0, lcmp), nrhsqb0))*mb_a) + mb_a*mb_a
end if,
where lcmp = lcm/NPROW with lcm = ilcm(NPROW,
NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol= indxg2p(ja, nb_a, MYROW, rsrc_a, NPROW)
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow,
NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol,
NPCOL),
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow,
NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol,
NPCOL),
ilcm, indxg2p and numroc are ScaLAPACK tool functions;
MYROW, MYCOL, NPROW, and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>a</i>	On exit, If $m \geq n$, $\text{sub}(A)$ is overwritten by the details of its QR factorization as returned by <code>p?geqrf</code> ; if $m < n$, $\text{sub}(A)$ is overwritten by details of its LQ factorization as returned by <code>p?gelqf</code> .
<i>b</i>	On exit, $\text{sub}(B)$ is overwritten by the solution vectors, stored columnwise: if $trans = 'N'$ and $m \geq n$, rows 1 to n of $\text{sub}(B)$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to m in that column; If $trans = 'N'$ and $m < n$, rows 1 to n of $\text{sub}(B)$ contain the minimum norm solution vectors; If $trans = 'T'$ and $m \geq n$, rows 1 to m of $\text{sub}(B)$ contain the minimum norm solution vectors; if $trans = 'T'$ and $m < n$, rows 1 to m of $\text{sub}(B)$ contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to n in that column.
<i>work(1)</i>	On exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) INTEGER. = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

```
call pssyev( jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
info )
```

```
call pdsyev( jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
info )
```

Description

This routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix *A* by calling the recommended sequence of ScaLAPACK routines.

In its present form, the routine assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global). CHARACTER. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:

If *jobz* = 'N', then only eigenvalues are computed.

If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global). CHARACTER. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix *A* is stored:

If *uplo* = 'U', *a* stores the upper triangular part of *A*.

If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* ($n \geq 0$).

a (local)

REAL for pssyev.
 DOUBLE PRECISION for pdsyev.
 Block cyclic array of global dimension (n, n) and local dimension $(lld\_a, LOC\ c(ja+n-1))$. On entry, the symmetric matrix A .
 If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the symmetric matrix.
 If $uplo = 'L'$, only the lower triangular part of A is used to define the elements of the symmetric matrix.

ia, ja (global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca (global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix A .

iz, jz (global) INTEGER. The row and column indices in the global array z indicating the first row and the first column of the submatrix Z , respectively.

descz (global and local) INTEGER array, dimension $(dlen\_)$. The array descriptor for the distributed matrix Z .

work (local)
 REAL for pssyev.
 DOUBLE PRECISION for pdsyev.
 Array, DIMENSION $(lwork)$.

lwork (local) INTEGER. See below for definitions of variables used to define $lwork$.
 If no eigenvectors are requested ($jobz = 'N'$), then $lwork \geq 5*n + sizesytrd + 1$,
 where $sizesytrd$ is the workspace for `p?sytrd` and is $\max(NB*(np + 1), 3*NB)$.
 If eigenvectors are requested ($jobz = 'V'$) then the amount of workspace required to guarantee that all eigenvectors are computed is:
 $qrmem = 2*n-2$
 $lwmin = 5*n + n*ldc + \max(sizemqrleft, qrmem) + 1$
 Variable definitions:

```

nb = desca(mb_) = desca(nb_) = descz(mb_) =
descz(nb_);
nn = max(n, nb, 2);
desca(rsrc_) = desca(rsrc_) = descz(rsrc_) =
descz(csrc_) = 0
np = numroc(nn, nb, 0, 0, NPROW)
nq = numroc(max(n, nb, 2), nb, 0, 0, NPCOL)
nrc = numroc(n, nb, myprowc, 0, NPROCS)
ldc = max(1, nrc)
sizemqrleft is the workspace for p?ormtr when its side
argument is 'L'.
myprowc is defined when a new context is created as follows:
call blacs_get(desca(ctxt_), 0, contextc)
call blacs_gridinit(contextc, 'R', NPROCS, 1)
call blacs_gridinfo(contextc, nprowc, npcolc,
myprowc, mypcolc)

```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>A</i> , including the diagonal, is destroyed.
<i>w</i>	(global). REAL for <i>pssyev</i> DOUBLE PRECISION for <i>pdsyev</i> Array, DIMENSION (<i>n</i>). On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). REAL for <i>pssyev</i> DOUBLE PRECISION for <i>pdsyev</i> Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues.

If *jobz* = 'N', then *z* is not referenced.

work(1) On output, *work(1)* returns the workspace needed to guarantee completion. If the input parameters are incorrect, *work(1)* may also be incorrect.

If *jobz* = 'N' *work(1)* = minimal (optimal) amount of workspace

If *jobz* = 'V' *work(1)* = minimal workspace required to generate all the eigenvectors.

info (global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0:

If *info* = 1 through *n*, the *i*-th eigenvalue did not converge in *steqr2* after a total of $30n$ iterations.

If *info* = *n*+1, then *p?syev* has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from *p?syev* cannot be guaranteed.

p?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

```
call pssyevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr,
gap, info)
```

```
call pdsyevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork, ifail, iclustr,
gap, info)
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

$jobz$ (global). CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors:
 If $jobz = 'N'$, then only eigenvalues are computed.
 If $jobz = 'V'$, then eigenvalues and eigenvectors are computed.

$range$ (global). CHARACTER*1. Must be 'A', 'V', or 'I'.
 If $range = 'A'$, all eigenvalues will be found.
 If $range = 'V'$, all eigenvalues in the half-open interval $[vl, vu]$ will be found.
 If $range = 'I'$, the eigenvalues with indices il through iu will be found.

$uplo$ (global). CHARACTER*1. Must be 'U' or 'L'.
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
 If $uplo = 'U'$, a stores the upper triangular part of A .
 If $uplo = 'L'$, a stores the lower triangular part of A .

n (global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).

a (local). REAL for pssyevx
 DOUBLE PRECISION for pdsyevx.
 Block cyclic array of global dimension (n, n) and local dimension $(lld\_a, LOCC(ja+n-1))$. On entry, the symmetric matrix A .
 If $uplo = 'U'$, only the upper triangular part of A is used to define the elements of the symmetric matrix.
 If $uplo = 'L'$, only the lower triangular part of A is used to define the elements of the symmetric matrix.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>vl, vu</i>	(global) REAL for pssyevx DOUBLE PRECISION for pdsyevx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1$ $\min(il, n) \leq iu \leq n$ Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). REAL for pssyevx DOUBLE PRECISION for pdsyevx. If <i>jobz</i> ='V', setting <i>abstol</i> to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with $((\text{mod}(info, 2) \neq 0) \text{ or } * (\text{mod}(info/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.

<i>orfac</i>	(global). REAL for pssyevx DOUBLE PRECISION for pdsyevx. Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol=orfac*norm(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>z</i>, respectively.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>z</i>. <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i>.
<i>work</i>	(local) REAL for pssyevx. DOUBLE PRECISION for pdsyevx. Array, DIMENSION (<i>lwork</i>).
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i>. See below for definitions of variables used to define <i>lwork</i>. If no eigenvectors are requested (<i>jobz</i> = 'N'), then <i>lwork</i> $\geq 5*n + \max(5*nn, NB*(np0 + 1))$. If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is: $lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) +$ $iceil(neig, NPROW*NPCOL)*nn$ The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and <i>orfac</i> is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to <i>lwork</i>: $(clustersize-1)*n,$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j)\} + orfac*2*norm(A),$$

where

neig = number of eigenvectors requested

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, *nb*, 2);

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0;

np0 = numroc(*nn*, *nb*, 0, 0, NPROW);

mq0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL)

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x/y*)

If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$$lwork \geq \max(lwork, 5*n + nsytrd_lwopt),$$

where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

$$nsytrd\_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;$$

```
anb = pjlaenv(desca(ctxt_), 3, 'p?sytttrd', 'L',
0, 0, 0, 0);
```

```
sqnpc = int(sqrt(dble(NPROW * NPCOL)));
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb);
```

numroc is a ScaLAPACK tool functions;

pjlaenv is a ScaLAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

For large n , no extra workspace is needed, however the biggest boost in performance comes for small n , so it is wise to provide the extra workspace (typically less than a megabyte per process).

If $clustersize > n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) p?stein will perform no better than ?stein on single processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$

reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by p?erbla.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*. $liwork \geq 6 \cdot nnp$

Where: $nnp = \max(n, NPROW \cdot NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of

these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.
<i>nz</i>	(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of <i>z</i> that are filled. If <i>jobz</i> $\neq$ 'V', <i>nz</i> is not referenced. If <i>jobz</i> = 'V', <i>nz</i> = <i>m</i> unless the user supplies insufficient space and <code>p?syevx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in <i>z</i> (<i>m.le.descz(n_)</i>) and sufficient workspace to compute them. (See <i>lwork</i>). <code>p?syevx</code> is always able to detect insufficient space without computation unless <i>range.eq.</i> 'V'.
<i>w</i>	(global). REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Array, DIMENSION (<i>n</i>). The first <i>m</i> elements contain the selected eigenvalues in ascending order.
<i>z</i>	(local). REAL for <code>pssyevx</code> DOUBLE PRECISION for <code>pdsyevx</code> . Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , <i>LOCc(jz+n-1)</i>). If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> .

	If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> (1)	On exit, returns workspace adequate workspace to allow optimal performance.
<i>iwork</i> (1)	On return, <i>iwork</i> (1) contains the amount of integer workspace required.
<i>ifail</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). If <i>jobz</i> = 'V', then on normal exit, the first <i>m</i> elements of <i>ifail</i> are zero. If (mod(<i>info</i> ,2) .ne.0) on exit, then <i>ifail</i> contains the indices of the eigenvectors that failed to converge. If <i>jobz</i> = 'N', then <i>ifail</i> is not referenced.
<i>iclustr</i>	(global) INTEGER. Array, DIMENSION (2*NPROW*NPCOL) This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see <i>lwork</i> , <i>orfac</i> and <i>info</i>). Eigenvectors corresponding to clusters of eigenvalues indexed <i>iclustr</i> (2*i-1) to <i>iclustr</i> (2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. <i>iclustr</i> () is a zero terminated array. (<i>iclustr</i> (2*k).ne.0. and. <i>iclustr</i> (2*k+1).eq.0) if and only if <i>k</i> is the number of clusters. <i>iclustr</i> is not referenced if <i>jobz</i> = 'N'.
<i>gap</i>	(global) REAL for pssyevx DOUBLE PRECISION for pdsyevx. Array, DIMENSION (NPROW*NPCOL) This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array <i>iclustr</i> . As a result, the dot product between eigenvectors corresponding to the <i>i</i> th cluster may be as high as (C*n)/ <i>gap</i> (<i>i</i>) where <i>C</i> is a small constant.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0:

If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$: if $(\text{mod}(info,2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in $ifail$. Ensure $abstol=2.0*p?lamch('U')$.

If $(\text{mod}(info/2,2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array $iclustr$.

If $(\text{mod}(info/4,2) \neq 0)$, then space limit prevented $p?syevxf$ from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in nz .

If $(\text{mod}(info/8,2) \neq 0)$, then $p?stebz$ failed to compute eigenvalues. Ensure $abstol=2.0*p?lamch('U')$.

p?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```
call pcheevx( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork,
ifail, iclustr, gap, info )
```

```
call pzheevx( jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol,
m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork,
ifail, iclustr, gap, info )
```

Description

This routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	(global). CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval $[vl, vu]$ will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). COMPLEX for pcheevx DOUBLE COMPLEX for pzheevx. Block cyclic array of global dimension (<i>n</i> , <i>n</i>) and local dimension (<i>lld_a</i> , <i>LOC c(ja+n-1)</i>). On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.

<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, <i>p?heevx</i> cannot guarantee correct error reporting
<i>vl, vu</i>	(global) REAL for <i>pcheevx</i> DOUBLE PRECISION for <i>pzheevx</i> . If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1; \min(il, n) \leq iu \leq n$. Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). REAL for <i>pcheevx</i> DOUBLE PRECISION for <i>pzheevx</i> . If <i>jobz</i> ='V', setting <i>abstol</i> to <i>p?lamch(context, 'U')</i> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues are computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$, not zero. If this routine returns with $((\text{mod}(\text{info}, 2) \neq 0) \text{ or } (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.
<i>orfac</i>	(global). REAL for <i>pcheevx</i> DOUBLE PRECISION for <i>pzheevx</i> .

	Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> . <i>descz</i> (<i>ctxt_</i>) must equal <i>desca</i> (<i>ctxt_</i>).
<i>work</i>	(local) COMPLEX for <i>pcheevx</i> DOUBLE COMPLEX for <i>pzheevx</i> . Array, DIMENSION (<i>lwork</i>).
<i>lwork</i>	(local). INTEGER. The dimension of the array <i>work</i> . If only eigenvalues are requested: $lwork \geq n + \max(nb * (np0 + 1), 3)$ If eigenvectors are requested: $lwork \geq n + (np0 + mq0 + nb) * nb$ with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$. $lwork \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{iceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$ For optimal performance, greater workspace is needed, that is $lwork \geq \max(lwork, nhetrd\_lwork)$ where <i>lwork</i> is as defined above, and <i>nhetrd_lwork</i> = $n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$ $ictxt = \text{desca}(ctxt\_)$ $anb = \text{pjlavenv}(ictxt, 3, 'pchettrd', 'L', 0, 0, 0, 0)$ $sqnpc = \text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL}))$

```

nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
If lwork = -1, then lwork is global input and a workspace
query is assumed; the routine only calculates the size
required for optimal performance for all work arrays. Each
of these values is returned in the first entry of the
corresponding work arrays, and no error message is issued
by pxxerbla.

rwork      (local)
            REAL for pcheevx
            DOUBLE PRECISION for pzheevx.
            Workspace array, DIMENSION (lrwork).

lrwork     (local) INTEGER. The dimension of the array work.
            See below for definitions of variables used to define lrwork.
            If no eigenvectors are requested (jobz = 'N'), then
            lrwork ≥ 5*nn+4*n.
            If eigenvectors are requested (jobz = 'V'), then the
            amount of workspace required to guarantee that all
            eigenvectors are computed is:
            lrwork ≥ 4*n + max(5*nn, np0*mq0+2*nb*nb) +
            iceil(neig, NPROW*NPCOL)*nn
            The computed eigenvectors may not be orthogonal if the
            minimal workspace is supplied and orfac is too small. If
            you want to guarantee orthogonality (at the cost of
            potentially poor performance) you should add the following
            values to lrwork:
            (clustersize-1)*n,
            where clustersize is the number of eigenvalues in the
            largest cluster, where a cluster is defined as a set of close
            eigenvalues:
            {w(k), ..., w(k+clustersize-1) | w(j+1) ≤
            w(j)+orfac*2*norm(A)}.
            Variable definitions:
            neig = number of eigenvectors requested;
            nb = desca(mb_) = desca(nb_) = descz(mb_) =
            descz(nb_);
            nn = max(n, NB, 2);

```

```
desca(rsrc_) = desca(nb_) = descz(rsrc_) =
descz(csrc_) = 0;
np0 = numroc(nn, nb, 0, 0, NPROW);
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL);
iceil(x, y) is a ScaLAPACK function returning ceiling(x/y)
When lwork is too small:
```

If *lwork* is too small to guarantee orthogonality, p?heevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned. Note that when *range*='V', p?heevx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow p?heevx to compute the eigenvalues, p?heevx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If $clustersize \geq n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) p?stein will perform no better than ?stein on 1 processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by p?xerbla.

iwork (local) INTEGER. Workspace array.
liwork (local) INTEGER, dimension of *iwork*.
 $liwork \geq 6 * nnp$
 Where: $nnp = \max(n, NPROW * NPCOL + 1, 4)$
 If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L'), or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m (global) INTEGER. The total number of eigenvalues found;
 $0 \leq m \leq n$.

nz (global) INTEGER. Total number of eigenvectors computed.
 $0 \leq nz \leq m$.
 The number of columns of *z* that are filled.
 If *jobz* ≠ 'V', *nz* is not referenced.
 If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and p_?heevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m.le.descz(n_)*) and sufficient workspace to compute them. (See *lwork*). p_?heevx is always able to detect insufficient space without computation unless *range.eq.'V'*.

w (global).
 REAL for pcheevx
 DOUBLE PRECISION for pzheevx.
 Array, DIMENSION (*n*). The first *m* elements contain the selected eigenvalues in ascending order.

z (local).

COMPLEX for pcheevx
DOUBLE COMPLEX for pzheevx.
Array, global dimension (n, n), local dimension ($l1d\_z, LOcc(jz+n-1)$).
If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.
If $jobz = 'N'$, then z is not referenced.

work(1) On exit, returns workspace adequate workspace to allow optimal performance.

rwork (local).
REAL for pcheevx
DOUBLE PRECISION for pzheevx.
Array, DIMENSION ($lrwork$). On return, $rwork(1)$ contains the optimal amount of workspace required for efficient execution.
If $jobz='N'$ $rwork(1)$ = optimal amount of workspace required to compute eigenvalues efficiently.
If $jobz='V'$ $rwork(1)$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.
If $range='V'$, it is assumed that all eigenvectors may be required.

iwork(1) (local)
On return, $iwork(1)$ contains the amount of integer workspace required.

ifail (global) INTEGER.
Array, DIMENSION (n).
If $jobz = 'V'$, then on normal exit, the first m elements of $ifail$ are zero. If $(mod(info, 2) \neq 0)$ on exit, then $ifail$ contains the indices of the eigenvectors that failed to converge.
If $jobz = 'N'$, then $ifail$ is not referenced.

iclustr (global) INTEGER.
Array, DIMENSION ($2*NPROW*NPCOL$).

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. (*iclustr*(2*k).ne.0. and. *iclustr*(2*k+1).eq.0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array, DIMENSION (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$ where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(i*100+j), if the *i*-th argument is a scalar and had an illegal value, then *info* = -i.

If *info* > 0:

If (mod(*info*,2).ne.0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U')

If (mod(*info*/2,2).ne.0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented `p?syevx` from computing all of the eigenvectors between `vl` and `vu`. The number of eigenvectors computed is returned in `nz`.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then `p?stebz` failed to compute eigenvalues. Ensure `abstol=2.0*p?lamch('U')`.

p?gesvd

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

```
call psgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
  ivt, jvt, descvt, work, lwork, info )

call pdgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
  ivt, jvt, descvt, work, lwork, info )

call pcgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
  ivt, jvt, descvt, work, lwork, rwork, info )

call pzgesvd( jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt,
  ivt, jvt, descvt, work, lwork, rwork, info )
```

Description

This routine computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array `s` in decreasing order and only the first $\min(m, n)$ columns of U and rows of `vt` = V^T are computed.

Input Parameters

`mp` = number of local rows in A and U

nq = number of local columns in A and VT

$size = \min(m, n)$

$sizeq$ = number of local columns in U

$sizep$ = number of local rows in VT

jobu (global). CHARACTER*1. Specifies options for computing all or part of the matrix U .

If *jobu* = 'V', the first *size* columns of U (the left singular vectors) are returned in the array *u*;

If *jobu* = 'N', no columns of U (no left singular vectors) are computed.

jobvt (global) CHARACTER*1.

Specifies options for computing all or part of the matrix V^T .

If *jobvt* = 'V', the first *size* rows of V^T (the right singular vectors) are returned in the array *vt*;

If *jobvt* = 'N', no rows of V^T (no right singular vectors) are computed.

m (global) INTEGER. The number of rows of the matrix A ($m \geq 0$).

n (global) INTEGER. The number of columns in A ($n \geq 0$).

a (local). REAL for *psgesvd*
DOUBLE PRECISION for *pdgesvd*
COMPLEX for *pcgesvd*
COMPLEX*16 for *pzgesvd*
Block cyclic array, global dimension (m, n), local dimension (mp, nq).

work(lwork) is a workspace array.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix A , respectively.

desca (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix A .

iu, ju (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix U , respectively.

<i>descu</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>U</i> .
<i>ivt, jvt</i>	(global) INTEGER. The row and column indices in the global array <i>vt</i> indicating the first row and the first column of the submatrix <i>VT</i> , respectively.
<i>descvt</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>VT</i> .
<i>work</i>	(local). REAL for <i>psgesvd</i> DOUBLE PRECISION for <i>pdgesvd</i> COMPLEX for <i>pcgesvd</i> COMPLEX*16 for <i>pzgesvd</i> Workspace array, dimension (<i>lwork</i>)
<i>lwork</i>	(local) INTEGER. The dimension of the array <i>work</i> ; $lwork > 2 + 6 * sizeb + \max(watobd, wbdtosvd)$, where $sizeb = \max(m, n)$, and <i>watobd</i> and <i>wbdtosvd</i> refer, respectively, to the workspace required to bidiagonalize the matrix <i>A</i> and to go from the bidiagonal matrix to the singular value decomposition $U S VT$. For <i>watobd</i> , the following holds: $watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d))$, where <i>wp?lange</i> , <i>wp?lared1d</i> , <i>wp?lared2d</i> , <i>wp?gebrd</i> are the workspaces required respectively for the subprograms <i>p?lange</i> , <i>p?lared1d</i> , <i>p?lared2d</i> , <i>p?gebrd</i> . Using the standard notation $mp = \text{numroc}(m, mb, MYROW, \text{desca}(ctxt\_), NPROW)$, $nq = \text{numroc}(n, nb, MYCOL, \text{desca}(lld\_), NPCOL)$, the workspaces required for the above subprograms are $wp?lange = mp$, $wp?lared1d = nq0$, $wp?lared2d = mp0$, $wp?gebrd = nb * (mp + nq + 1) + nq$, where <i>nq0</i> and <i>mp0</i> refer, respectively, to the values obtained at <i>MYCOL</i> = 0 and <i>MYROW</i> = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0): $watobd \leq nb * (mp0 + nq0 + 1) + nq0$.

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For *wbdtosvd*, the following holds:

$$wbdtosvd = size * (wantu * nru + wantvt * ncvt) + \max(w?bdsqr, \max(wantu * wp?ormbrqln, wantvt * wp?ormbrprt)),$$

where

$wantu(wantvt) = 1$, if left/right singular vectors are wanted, and $wantu(wantvt) = 0$, otherwise. *w?bdsqr*, *wp?ormbrqln*, and *wp?ormbrprt* refer respectively to the workspace required for the subprograms *?bdsqr*, *p?ormbr(qln)*, and *p?ormbr(prt)*, where *qln* and *prt* are the values of the arguments *vect*, *side*, and *trans* in the call to *p?ormbr*. *nru* is equal to the local number of rows of the matrix *U* when distributed 1-dimensional "column" of processes. Analogously, *ncvt* is equal to the local number of columns of the matrix *VT* when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure *?bdsqr* requires

$$w?bdsqr = \max(1, 2 * size + (2 * size - 4) * \max(wantu, wantvt))$$

on every processor. Finally,

$$\begin{aligned} wp?ormbrqln &= \max((nb * (nb - 1)) / 2, \\ &\quad (sizeq + mp) * nb) + nb * nb, \\ wp?ormbrprt &= \max((mb * (mb - 1)) / 2, \\ &\quad (sizep + nq) * mb) + mb * mb, \end{aligned}$$

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum size for the work array. The required workspace is returned as the first element of *work* and no error message is issued by *pxerbla*.

rwork

REAL for *psgesvd*
 DOUBLE PRECISION for *pdgesvd*
 COMPLEX for *pcgesvd*
 COMPLEX*16 for *pzgesvd*
 Workspace array, dimension $(1 + 4 * sizeb)$

Output Parameters

<i>a</i>	On exit, the contents of <i>a</i> are destroyed.
<i>s</i>	(global). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd Array, DIMENSION (<i>size</i>). Contains the singular values of <i>A</i> sorted so that $s(i) \geq s(i+1)$.
<i>u</i>	(local). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd local dimension (<i>mp</i> , <i>sizeq</i>), global dimension (<i>m</i> , <i>size</i>) If <i>jobu</i> = 'V', <i>u</i> contains the first min(<i>m</i> , <i>n</i>) columns of <i>U</i> . If <i>jobu</i> = 'N' or 'O', <i>u</i> is not referenced.
<i>vt</i>	(local). REAL for psgesvd DOUBLE PRECISION for pdgesvd COMPLEX for pcgesvd COMPLEX*16 for pzgesvd local dimension (<i>sizep</i> , <i>nq</i>), global dimension (<i>size</i> , <i>n</i>) If <i>jobvt</i> = 'V', <i>vt</i> contains the first <i>size</i> rows of V^T if <i>jobu</i> = 'N', <i>vt</i> is not referenced.
<i>work</i>	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i>	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required size of <i>rwork</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value. If <i>info</i> > 0 <i>i</i> , then if ?bdsqr did not converge, If <i>info</i> = min(<i>m</i> , <i>n</i>) + 1, then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed.

p?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```
call pssygvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
             vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork,
             liwork, ifail, iclustr, gap, info)
```

```
call pdsygvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
             vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork,
             liwork, ifail, iclustr, gap, info)
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{ sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here x denotes eigen vectors, λ (*lambda*) denotes eigenvalues, $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ is assumed to symmetric, and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \lambda * \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \lambda * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \lambda * x$.
<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global). CHARACTER*1. Must be 'A' or 'V' or 'I'.

	If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval: [<i>vl</i>, <i>vu</i>] If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i>.
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of sub(<i>A</i>) and sub(<i>B</i>); If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of sub(<i>A</i>) and sub(<i>B</i>).
<i>n</i>	(global). INTEGER. The order of the matrices sub(<i>A</i>) and sub(<i>B</i>), $n \geq 0$.
<i>a</i>	(local) REAL for pssygvx DOUBLE PRECISION for pdsygvx. Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> symmetric distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>. If <i>desca(ctxt_)</i> is incorrect, p?sygvx cannot guarantee correct error reporting.
<i>b</i>	(local). REAL for pssygvx DOUBLE PRECISION for pdsygvx. Pointer into the local memory to an array of dimension (<i>lld_b</i>, <i>LOCc(jb+n-1)</i>). On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> symmetric distributed matrix sub(<i>B</i>).

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of *sub(B)* contains the upper triangular part of the matrix.
 If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of *sub(A)* contains the lower triangular part of the matrix.

ib, jb (global) INTEGER. The row and column indices in the global array *b* indicating the first row and the first column of the submatrix *B*, respectively.

descb (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *B*. *descb(ctxt_)* must be equal to *desca(ctxt_)*.

vl, vu (global)
 REAL for pssygvx
 DOUBLE PRECISION for pdsygvx.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu (global)
 INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint:
 $il \geq 1, \min(il, n) \leq iu \leq n$
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol (global)
 REAL for pssygvx
 DOUBLE PRECISION for pdsygvx.
 If *jobz*='V', setting *abstol* to *p?lamch(context, 'U')* yields the most orthogonal eigenvectors.
 The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to
 $abstol + eps * \max(|a|, |b|)$,
 where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps*norm(T)* will be used in its place, where *norm(T)* is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

	Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with $((mod(info,2).ne.0).or.*(mod(info/8,2).ne.0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.
<i>orfac</i>	(global). REAL for pssygvx DOUBLE PRECISION for pdsygvx. Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * norm(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>z</i>, respectively.
<i>descz</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>z</i>. <i>descz(ctxt_)</i> must equal <i>desca(ctxt_)</i>.
<i>work</i>	(local) REAL for pssygvx DOUBLE PRECISION for pdsygvx. Workspace array, dimension (<i>lwork</i>)
<i>lwork</i>	(local) INTEGER. Dimension of the array <i>work</i>. See below for definitions of variables used to define <i>lwork</i>. If no eigenvectors are requested (<i>jobz</i> = 'N'), then <i>lwork</i> $\geq 5 * n + \max(5 * nn, NB * (np0 + 1))$. If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

```

lwork ≥ 5*n + max(5*nn, np0*mq0 + 2*nb*nb) +
iceil(neig, NPROW*NPCOL)*nn.

```

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

```
(clustersize-1)*n,
```

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

```
{w(k), ..., w(k+clustersize-1) | w(j+1) ≤ w(j) +
orfac*2*norm(A) }
```

Variable definitions:

neig = number of eigenvectors requested,

```
nb = desca(mb_) = desca(nb_) = descz(mb_) =
descz(nb_),
```

```
nn = max(n, nb, 2),
```

```
desca(rsrc_) = desca(nb_) = descz(rsrc_) =
descz(csrc_) = 0,
```

```
np0 = numroc(nn, nb, 0, 0, NPROW),
```

```
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)
```

iceil(*x*, *y*) is a ScaLAPACK function returning $\lceil x/y \rceil$

If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible. Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

```

lwork ≥ max(lwork, 5*n + nsytrd_lwopt,
nsygst_lwopt), where
lwork, as defined previously, depends upon the number of
eigenvectors requested, and
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) +
(nps+3)*nps
nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb
anb = pjlalenv(desca(ctxt_), 3, p?sytrd 'L',
0, 0, 0, 0)
sqnpc = int(sqrt(dble(NPROW * NPCOL)))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
NB = desca(mb_)
np0 = numroc(n, nb, 0, 0, NPROW)
nq0 = numroc(n, nb, 0, 0, NPCOL)
numroc is a ScaLAPACK tool functions;

```

pjlalenv is a ScaLAPACK environmental inquiry function
MYROW, MYCOL, NPROW and NPCOL can be determined by
calling the subroutine blacs_gridinfo.

For large n , no extra workspace is needed, however the
biggest boost in performance comes for small n , so it is wise
to provide the extra workspace (typically less than a
Megabyte per process).

If $clustersize \geq n/\sqrt{NPROW \cdot NPCOL}$, then providing
enough space to compute all the eigenvectors orthogonally
will cause serious degradation in performance. At the limit
(that is, $clustersize = n-1$) p?stein will perform no
better than ?stein on a single processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$
reorthogonalizing all eigenvectors will increase the total
execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time
will grow as the square of the cluster size, all other factors
remaining equal and assuming enough workspace. Less
workspace means less reorthogonalization but faster
execution.

If $lwork = -1$, then $lwork$ is global input and a workspace
query is assumed; the routine only calculates the size
required for optimal performance for all work arrays. Each

of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*.

$liwork \geq 6 * nnp$

Where:

$nnp = \max(n, NPROW * NPCOL + 1, 4)$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit,

If *jobz* = 'V', and if *info* = 0, `sub(A)` contains the distributed matrix *Z* of eigenvectors. The eigenvectors are normalized as follows:

for *ibtype* = 1 or 2, $Z^T * \text{sub}(B) * Z = I$;

for *ibtype* = 3, $Z^T * \text{inv}(\text{sub}(B)) * Z = I$.

If *jobz* = 'N', then on exit the upper triangle (if *uplo*='U') or the lower triangle (if *uplo*='L') of `sub(A)`, including the diagonal, is destroyed.

b

On exit, if *info* ≤ *n*, the part of `sub(B)` containing the matrix is overwritten by the triangular factor *U* or *L* from the Cholesky factorization $\text{sub}(B) = U^T * U$ or $\text{sub}(B) = L * L^T$.

m

(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

nz

(global) INTEGER.

Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of *z* that are filled.

If *jobz* ≠ 'V', *nz* is not referenced.

If *jobz* = 'V', *nz* = *m* unless the user supplies insufficient space and *p?sygvx* is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (*m.le.descz(n_)*) and sufficient workspace to compute them. (See *lwork* below.) *p?sygvx* is always able to detect insufficient space without computation unless *range.eq.'V'*.

w

(global)

REAL for *pssygvx*

DOUBLE PRECISION for *pdsygvx*.

Array, DIMENSION (*n*). On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z

(local).

REAL for *pssygvx*

DOUBLE PRECISION for *pdsygvx*.

global dimension (*n*, *n*), local dimension (*lld_z*, *LOCc(jz+n-1)*).

If *jobz* = 'V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

work

If *jobz*='N' *work*(1) = optimal amount of workspace required to compute eigenvalues efficiently

If *jobz* = 'V' *work*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required.

ifail

(global) INTEGER.

Array, DIMENSION (*n*).

ifail provides additional information when *info.ne.0*

If $(\text{mod}(\text{info}/16, 2) \neq 0)$ then *ifail*(1) indicates the order of the smallest minor which is not positive definite. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge. If neither of the above error conditions hold and *jobz* = 'V', then the first *m* elements of *ifail* are set to zero.

iclustr

(global) INTEGER.

Array, DIMENSION $(2 * \text{NPROW} * \text{NPCOL})$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*).

Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array.

$(\text{iclustr}(2*k) \neq 0 \text{ and } \text{iclustr}(2*k+1) \neq 0)$ if and only if *k* is the number of clusters *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Array, DIMENSION $(\text{NPROW} * \text{NPCOL})$. This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C * n) / \text{gap}(i)$, where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i * 100 + j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If $(\text{mod}(\text{info}, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(\text{info}/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(\text{info}/4, 2) \neq 0)$, then space limit prevented *p?sygvx* from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then *p?stebz* failed to compute eigenvalues.

If $(\text{mod}(\text{info}/16, 2) \neq 0)$, then *B* was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

p?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem.

Syntax

```
call pchegvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork,
lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

```
call pzhegvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb,
vl, vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork,
lrwork, iwork, liwork, ifail, iclustr, gap, info)
```

Description

This routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \quad \text{sub}(A) * \text{sub}(B) * x = \lambda * x, \quad \text{or} \quad \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here *sub(A)* denoting *A*(*ia:ia+n-1, ja:ja+n-1*) and *sub(B)* are assumed to be Hermitian and *sub(B)* denoting *B*(*ib:ib+n-1, jb:jb+n-1*) is also positive definite.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \text{lambda} * \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \text{lambda} * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \text{lambda} * x$.
<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global). CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval: [<i>vl</i>, <i>vu</i>] If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i>.
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$.
<i>n</i>	(global). INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) COMPLEX for pchegvx DOUBLE COMPLEX for pzhegvx. Pointer into the local memory to an array of dimension (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>. If <i>desca(ctxt_)</i> is incorrect, p?hegvx cannot guarantee correct error reporting.
<i>b</i>	(local). COMPLEX for pchegvx DOUBLE COMPLEX for pzhegvx. Pointer into the local memory to an array of dimension (<i>lld_b</i>, <i>LOCc(jb+n-1)</i>). On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> Hermitian distributed matrix sub(<i>B</i>). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(<i>B</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(<i>B</i>) contains the lower triangular part of the matrix.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i>, respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i>. <i>descb(ctxt_)</i> must be equal to <i>desca(ctxt_)</i>.
<i>vl, vu</i>	(global) REAL for pchegvx DOUBLE PRECISION for pzhegvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$

If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol (global)
 REAL for pchegvx
 DOUBLE PRECISION for pzhegvx.
 If *jobz*='V', setting *abstol* to $p?lamch(context, 'U')$ yields the most orthogonal eigenvectors.
 The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to
 $abstol + eps * \max(|a|, |b|)$,
 where *eps* is the machine precision. If *abstol* is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.
 Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with
 $(\text{mod}(info, 2) \neq 0) \text{ or } * (\text{mod}(info/8, 2) \neq 0)$,
 indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to $2 * p?lamch('S')$.

orfac (global).
 REAL for pchegvx
 DOUBLE PRECISION for pzhegvx.
 Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz (global) INTEGER. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *Z*. *descz*(*ctxt_*) must equal *desca*(*ctxt_*).

work (local)
COMPLEX for *pchegvx*
DOUBLE COMPLEX for *pzhegvx*.
Workspace array, dimension (*lwork*)

lwork (local).
INTEGER. The dimension of the array *work*.
If only eigenvalues are requested:
 $lwork \geq n + \max(NB * (np0 + 1), 3)$
If eigenvectors are requested:
 $lwork \geq n + (np0 + mq0 + NB) * NB$
with $nq0 = \text{numroc}(nn, NB, 0, 0, NPCOL)$.
For optimal performance, greater workspace is needed, that is
 $lwork \geq \max(lwork, n, nhetr\_lwork, nhegst\_lwork)$
where *lwork* is as defined above, and
 $nhetr\_lwork = 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$;
 $nhegst\_lwork = 2 * np0 * nb + nq0 * nb + nb * nb$
 $nb = \text{desca}(mb\_)$
 $np0 = \text{numroc}(n, nb, 0, 0, NPROW)$
 $nq0 = \text{numroc}(n, nb, 0, 0, NPCOL)$
 $ictxt = \text{desca}(ctxt\_)$
 $anb = \text{pjlaenv}(ictxt, 3, 'p?hettrd', 'L', 0, 0, 0, 0)$
 $sqnpc = \text{sqrt}(\text{dble}(NPROW * NPCOL))$
 $nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$
numroc is a ScaLAPACK tool functions;
pjlaenv is a ScaLAPACK environmental inquiry function
MYROW, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the subroutine *blacs_gridinfo*.
If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each

of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

rwork

(local)
 REAL for `pchegvx`
 DOUBLE PRECISION for `pzhgvx`.
 Workspace array, DIMENSION (*lrwork*).

lrwork

(local) INTEGER. The dimension of the array *rwork*.
 See below for definitions of variables used to define *lrwork*.
 If no eigenvectors are requested (*jobz* = 'N'), then

$$lrwork \geq 5*nn+4*n$$

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lrwork \geq 4*n + \max(5*nn, np0*mq0) + \text{iceil}(neig, \text{NPROW}*NPCOL) * nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lrwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) \mid w(j+1) \leq w(j) + orfac*2*norm(A)\}$$

Variable definitions:

neig = number of eigenvectors requested;

nb = *desca*(*mb_*) = *desca*(*nb_*) = *descz*(*mb_*) = *descz*(*nb_*);

nn = max(*n*, *nb*, 2);

desca(*rsrc_*) = *desca*(*nb_*) = *descz*(*rsrc_*) = *descz*(*csrc_*) = 0;

np0 = numroc(*nn*, *nb*, 0, 0, NPROW);

mq0 = numroc(max(*neig*, *nb*, 2), *nb*, 0, 0, NPCOL);

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*).

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, *p?hegvx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', *p?hegvx* does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow *p?hegvx* to compute the eigenvalues, *p?hegvx* will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If *clustersize* > $n/\sqrt{\text{NPROW}*\text{NPCOL}}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, *clustersize* = *n*-1) *p?stein* will perform no better than *?stein* on 1 processor.

For *clustersize* = $n/\sqrt{\text{NPROW}*\text{NPCOL}}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize* > $n/\sqrt{\text{NPROW}*\text{NPCOL}}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by *pxerbla*.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*.

$liwork \geq 6*nnp$

Where: $nnp = \max(n, \text{NPROW}*\text{NPCOL} + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a	On exit, if $jobz = 'V'$, then if $info = 0$, $sub(A)$ contains the distributed matrix Z of eigenvectors. The eigenvectors are normalized as follows: If $ibtype = 1$ or 2, then $Z^H * sub(B) * Z = i$; If $ibtype = 3$, then $Z^H * inv(sub(B)) * Z = i$. If $jobz = 'N'$, then on exit the upper triangle (if $uplo='U'$) or the lower triangle (if $uplo='L'$) of $sub(A)$, including the diagonal, is destroyed.
b	On exit, if $info \leq n$, the part of $sub(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $sub(B) = U^H * U$, or $sub(B) = L * L^H$.
m	(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.
nz	(global) INTEGER. Total number of eigenvectors computed. $0 < nz < m$. The number of columns of z that are filled. If $jobz \neq 'V'$, nz is not referenced. If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and <code>p?hegvx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z (m. <i>le.</i> $descz(n_)$) and sufficient workspace to compute them. (See $lwork$ below.) The routine <code>p?hegvx</code> is always able to detect insufficient space without computation unless $range = 'V'$.
w	(global) REAL for <code>pchegvx</code> DOUBLE PRECISION for <code>pzhegvx</code>.

	Array, DIMENSION (n). On normal exit, the first m entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). COMPLEX for pchegvx DOUBLE COMPLEX for pzhegvx. global dimension (n, n), local dimension (lld_z, $LOCc(jz+n-1)$). If <i>jobz</i> = 'V', then on normal exit the first m columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of <i>z</i> contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i>. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i>	On exit, <i>work</i> (1) returns the optimal amount of workspace.
<i>rwork</i>	On exit, <i>rwork</i>(1) contains the amount of workspace required for optimal efficiency If <i>jobz</i>='N' <i>rwork</i>(1) = optimal amount of workspace required to compute eigenvalues efficiently If <i>jobz</i>='V' <i>rwork</i>(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality. If <i>range</i>='V', it is assumed that all eigenvectors may be required when computing optimal workspace.
<i>ifail</i>	(global) INTEGER. Array, DIMENSION (n). <i>ifail</i> provides additional information when <i>info.ne.0</i> If (<i>mod</i>(<i>info</i>/16,2).ne.0), then <i>ifail</i>(1) indicates the order of the smallest minor which is not positive definite. If (<i>mod</i>(<i>info</i>,2).ne.0) on exit, then <i>ifail</i>(1) contains the indices of the eigenvectors that failed to converge. If neither of the above error conditions are held, and <i>jobz</i> = 'V', then the first m elements of <i>ifail</i> are set to zero.
<i>iclustr</i>	(global) INTEGER. Array, DIMENSION (2*NPROW*NPCOL). This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to

insufficient workspace (see *lwork*, *orfac* and *info*).
 Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

iclustr() is a zero terminated array.

(*iclustr*(2*k) .ne.0 .and. *iclustr*(2*k+1) .eq.0) if and only if *k* is the number of clusters.

iclustr is not referenced if *jobz* = 'N'.

gap

(global)

REAL for pchegvx

DOUBLE PRECISION for pzhegvx.

Array, DIMENSION (NPROW*NPCOL).

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$, where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0: the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(i*100+j), if the *i*-th argument is a scalar and had an illegal value, then *info* = -i.

If *info* > 0:

If (mod(*info*,2) .ne.0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If (mod(*info*,2,2) .ne.0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2) .ne.0), then space limit prevented p?sygvx from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(\text{info}/8, 2) \neq 0)$, then `p?stebz` failed to compute eigenvalues.

If $(\text{mod}(\text{info}/16, 2) \neq 0)$, then B was not positive definite. `ifail(1)` indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary and Utility Routines

7

This chapter describes the Intel® Math Kernel Library implementation of ScaLAPACK [Auxiliary Routines](#) and [Utility Functions and Routines](#). The library includes routines for both real and complex data.

NOTE. ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Routine naming conventions, mathematical notation, and matrix storage schemes used for ScaLAPACK auxiliary and utility routines are the same as described in previous chapters. Some routines and functions may have combined character codes, such as `sc` or `dz`. For example, the routine `pscsum1` uses a complex input array and returns a real value.

Auxiliary Routines

Table 7-1 ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
<code>p?lacgv</code>	<code>c, z</code>	Conjugates a complex vector.
<code>p?max1</code>	<code>c, z</code>	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>p?amax</code> , but using the absolute value to the real part).
<code>?combamax1</code>	<code>c, z</code>	Finds the element with maximum real part absolute value and its corresponding global index.
<code>p?sum1</code>	<code>sc, dz</code>	Forms the 1-norm of a complex vector similar to Level 1 PBLAS <code>p?asum</code> , but using the true absolute value.
<code>p?dbtrsv</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting. The routine is called by <code>p?dbtrs</code> .
<code>p?dttrsv</code>	<code>s, d, c, z</code>	Computes an <i>LU</i> factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by <code>p?dttrs</code> .

Routine Name	Data Types	Description
p?gebd2	s, d, c, z	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
p?gehd2	s, d, c, z	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
p?gelq2	s, d, c, z	Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).
p?geql2	s, d, c, z	Computes a QL factorization of a general rectangular matrix (unblocked algorithm).
p?geqr2	s, d, c, z	Computes a QR factorization of a general rectangular matrix (unblocked algorithm).
p?gerq2	s, d, c, z	Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).
p?getf2	s, d, c, z	Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
p?labrd	s, d, c, z	Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .
p?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
p?laconsb	s, d	Looks for two consecutive small subdiagonal elements.
p?lACP2	s, d, c, z	Copies all or part of a distributed matrix to another distributed matrix.
p?lACP3	s, d	Copies from a global parallel array into a local replicated array or vice versa.
p?lACPY	s, d, c, z	Copies all or part of one two-dimensional array to another.

Routine Name	Data Types	Description
<code>p?laevswp</code>	<code>s, d, c, z</code>	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
<code>p?lahrd</code>	<code>s, d, c, z</code>	Reduces the first nb columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .
<code>p?laiect</code>	<code>s, d, c, z</code>	Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).
<code>p?lange</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
<code>p?lanhs</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.
<code>p?lansy, p?lanhe</code>	<code>s, d, c, z/c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
<code>p?lantr</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.
<code>p?lapiv</code>	<code>s, d, c, z</code>	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
<code>p?laqge</code>	<code>s, d, c, z</code>	Scales a general rectangular matrix, using row and column scaling factors computed by <code>p?geequ</code> .
<code>p?laqsy</code>	<code>s, d, c, z</code>	Scales a symmetric/Hermitian matrix, using scaling factors computed by <code>p?poequ</code> .
<code>p?laredld</code>	<code>s, d</code>	Redistributes an array assuming that the input array <code>bycol</code> is distributed across rows and that all process columns contain the same copy of <code>bycol</code> .

Routine Name	Data Types	Description
p?lared2d	<i>s, d</i>	Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .
p?larf	<i>s, d, c, z</i>	Applies an elementary reflector to a general rectangular matrix.
p?larfb	<i>s, d, c, z</i>	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
p?larfc	<i>c, z</i>	Applies the conjugate transpose of an elementary reflector to a general matrix.
p?larfg	<i>s, d, c, z</i>	Generates an elementary reflector (Householder matrix).
p?larft	<i>s, d, c, z</i>	Forms the triangular vector T of a block reflector $H=I-VTV^H$
p?larz	<i>s, d, c, z</i>	Applies an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzb	<i>s, d, c, z</i>	Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.
p?larzc	<i>c, z</i>	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzt	<i>s, d, c, z</i>	Forms the triangular factor T of a block reflector $H=I-VTV^H$ as returned by p?tzrzf .
p?lascl	<i>s, d, c, z</i>	Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} .
p?laset	<i>s, d, c, z</i>	Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β .
p?lasmsub	<i>s, d</i>	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
p?lassq	<i>s, d, c, z</i>	Updates a sum of squares represented in scaled form.

Routine Name	Data Types	Description
p?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
p?latra	s, d, c, z	Computes the trace of a general square distributed matrix.
p?latrd	s, d, c, z	Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.
p?latrz	s, d, c, z	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
p?lauu2	s, d, c, z	Computes the product UU^H or $L^H L$, where U and L are upper or lower triangular matrices (local unblocked algorithm).
p?lauum	s, d, c, z	Computes the product UU^H or $L^H L$, where U and L are upper or lower triangular matrices.
p?lawil	s, d	Forms the Wilkinson transform.
p?org2l/p?ung2l	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).
p?org2r/p?ung2r	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orgl2/p?ungl2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?orgr2/p?ungr2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?orm2l/p?unm2l	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).

Routine Name	Data Types	Description
p?orm2r/p?unm2r	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a <i>QR</i> factorization determined by p?geqrf (unblocked algorithm).
p?orml2/p?unml2	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an <i>LQ</i> factorization determined by p?gelqf (unblocked algorithm).
p?ormr2/p?unmr2	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an <i>RQ</i> factorization determined by p?gerqf (unblocked algorithm).
p?pbtrsv	<i>s, d, c, z</i>	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf .
p?pttrsv	<i>s, d, c, z</i>	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf .
p?potf2	<i>s, d, c, z</i>	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
p?rscl	<i>s, d, cs, zd</i>	Multiplies a vector by the reciprocal of a real scalar.
p?sygs2/p?hegs2	<i>s, d, c, z</i>	Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).
p?sytd2/p?hetd2	<i>s, d, c, z</i>	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
p?trti2	<i>s, d, c, z</i>	Computes the inverse of a triangular matrix (local unblocked algorithm).
?lamsh	<i>s, d</i>	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
?laref	<i>s, d</i>	Applies Householder reflectors to matrices on either their rows or columns.

Routine Name	Data Types	Description
<code>?lasorte</code>	<code>s, d</code>	Sorts eigenpairs by real and complex data types.
<code>?lasrt2</code>	<code>s, d</code>	Sorts numbers in increasing or decreasing order.
<code>?stein2</code>	<code>s, d</code>	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
<code>?dbtff2</code>	<code>s, d, c, z</code>	Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).
<code>?dbtrf</code>	<code>s, d, c, z</code>	Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).
<code>?dttrf</code>	<code>s, d, c, z</code>	Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
<code>?dttrsv</code>	<code>s, d, c, z</code>	Solves a general tridiagonal system of linear equations using the LU factorization computed by <code>?dttrf</code> .
<code>?pttrsv</code>	<code>s, d, c, z</code>	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the LDL^H factorization computed by <code>?pttrf</code> .
<code>?steqr2</code>	<code>s, d</code>	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

p?lacgv

Conjugates a complex vector.

Syntax

```
call pclacgv(n, x, ix, jx, descx, incx)
```

```
call pzlacgv(n, x, ix, jx, descx, incx)
```

Description

The routine conjugates a complex vector `sub(x)` of length n , where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx = m_x`, and $X(ix:ix+n-1, jx)$ if `incx = 1`.

Input Parameters

<i>n</i>	(global) INTEGER. The length of the distributed vector <code>sub(x)</code> .
<i>x</i>	(local). COMPLEX for <code>pclacgv</code> COMPLEX*16 for <code>pzlacgv</code> . Pointer into the local memory to an array of DIMENSION (<i>lld_x</i> , *). On entry the vector to be conjugated $x(i) = X(ix + (jx-1)*m_x + (i-1)*incx)$, $1 \leq i \leq n$.
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of <code>sub(x)</code> .
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of <code>sub(x)</code> .
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	(local). On exit, the conjugated vector.

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS `p?amax`, but using the absolute value to the real part).

Syntax

```
call pmax1(n, amax, indx, x, ix, jx, descx, incx)
call pzmax1(n, amax, indx, x, ix, jx, descx, incx)
```

Description

This routine computes the global index of the maximum element in absolute value of a distributed vector $\text{sub}(x)$. The global index is returned in indx and the value is returned in amax , where $\text{sub}(x)$ denotes $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$, $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m_x$.

Input Parameters

n	(global) pointer to INTEGER. The number of components of the distributed vector $\text{sub}(x)$. $n \geq 0$.
x	(local) COMPLEX for p _c max1. COMPLEX*16 for p _z max1 Array containing the local pieces of a distributed matrix of dimension of at least $((\text{jx}-1)*m_x + \text{ix} + (n-1)*\text{abs}(\text{incx}))$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix	(global) INTEGER. The row index in the global array x indicating the first row of $\text{sub}(x)$.
jx	(global) INTEGER. The column index in the global array x indicating the first column of $\text{sub}(x)$.
descx	(global and local) INTEGER. Array, DIMENSION (dlen_x) . The array descriptor for the distributed matrix x .
incx	(global) INTEGER. The global increment for the elements of x . Only two values of incx are supported in this version, namely 1 and m_x . incx must not be zero.

Output Parameters

amax	(global output) pointer to REAL. The absolute value of the largest entry of the distributed vector $\text{sub}(x)$ only in the scope of $\text{sub}(x)$.
indx	(global output) pointer to INTEGER. The global index of the element of the distributed vector $\text{sub}(x)$ whose real part has maximum absolute value.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

```
call ccombamax1(v1, v2)
```

```
call zcombamax1(v1, v2)
```

Description

This routine finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

<i>v1</i>	(local) COMPLEX for ccombamax1 COMPLEX*16 for zcombamax1 Array, DIMENSION 2. The first maximum absolute value element and its global index. <i>v1</i> (1)=amax, <i>v1</i> (2)=indx.
<i>v2</i>	(local) COMPLEX for ccombamax1 COMPLEX*16 for zcombamax1 Array, DIMENSION 2. The second maximum absolute value element and its global index. <i>v2</i> (1)=amax, <i>v2</i> (2)=indx.

Output Parameters

<i>v1</i>	(local). The first maximum absolute value element and its global index. <i>v1</i> (1)=amax, <i>v1</i> (2)=indx.

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.

Syntax

```
call pscsum1(n, asum, x, ix, jx, descx, incx)
```

```
call pdzsum1(n, asum, x, ix, jx, descx, incx)
```

Description

This routine returns the sum of absolute values of a complex distributed vector $\text{sub}(x)$ in *asum*, where $\text{sub}(x)$ denotes $X(ix:ix+n-1, jx:jx)$, if $incx = 1$, $X(ix:ix, jx:jx+n-1)$, if $incx = m_x$.

Based on p?asum from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

<i>n</i>	(global) INTEGER. The number of components of the distributed vector $\text{sub}(x)$. $n \geq 0$.
<i>x</i>	(local) COMPLEX for pscsum1 COMPLEX*16 for pdzsum1. Array containing the local pieces of a distributed matrix of dimension of at least $((jx-1)*m_x+ix+(n-1)*abs(incx))$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of $\text{sub}(x)$.
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of $\text{sub}(x)$.
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION 8. The array descriptor for the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x .

Output Parameters

<code>asum</code>	(local) Pointer to <code>REAL</code> . The sum of absolute values of the distributed vector <code>sub(x)</code> only in its scope.

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The routine is called by p?dbtrsv.

Syntax

```
call psdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pddbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pcdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)

call pzdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af,
laf, work, lwork, info)
```

Description

This routines solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs) \text{ (for real flavors); } A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs) \text{ (for complex flavors),}$$

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Gaussian elimination code PD@ (dom_pre) BTRF and is stored in $A(1:n, ja:ja+n-1)$ and `af`. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter `trans`.

Routine `p?dbtrf` must be called first.

Input Parameters

<i>uplo</i>	(global) CHARACTER. If <i>uplo</i> ='U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) CHARACTER. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$, if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix A_i ($n \geq 0$).
<i>bwl</i>	(global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.
<i>bwu</i>	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
<i>a</i>	(local). REAL for psdbtrsv DOUBLE PRECISION for pddbtrsv COMPLEX for pcdbrsv COMPLEX*16 for pzdbtrsv. Pointer into the local memory to an array with first DIMENSION $lld\_a \geq (bwl+bwu+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the n -by- n unsymmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>).

	if 1d type (<i>dtype_a</i> = 501 or 502), <i>dlen</i> ≥ 7; if 2d type (<i>dtype_a</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i>. Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdbtrsv DOUBLE PRECISION for pddbtrsv COMPLEX for pcdbrsv COMPLEX*16 for pzdbtrsv. Pointer into the local memory to an array of local lead DIMENSION <i>lld_b</i> ≥ <i>nb</i>. On entry, this array contains the local pieces of the right-hand sides <i>B(ib:ib+n-1, 1:nrhs)</i>.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). if 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; if 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i>. Contains information of mapping <i>B</i> to memory.
<i>laf</i>	(local) INTEGER. Size of user-input Auxiliary Filling space <i>af</i>. <i>laf</i> must be ≥ <i>nb</i> * (<i>bwl</i> + <i>bwu</i>) + 6 * max(<i>bwl</i>, <i>bwu</i>) * max(<i>bwl</i>, <i>bwu</i>). If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i>(1).
<i>work</i>	(local). REAL for psdbtrsv DOUBLE PRECISION for pddbtrsv COMPLEX for pcdbrsv COMPLEX*16 for pzdbtrsv. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i>.
<i>lwork</i>	(local or global) INTEGER.

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

$lwork \geq \max(bw1, bwu) * nrhs.$

Output Parameters

<i>a</i>	(local). This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix <i>x</i> .
<i>af</i>	(local). REAL for psdbtrsv DOUBLE PRECISION for pddbtrsv COMPLEX for pcdbtrsv COMPLEX*16 for pzdbtrsv. Auxiliary Filling Space. Filling is created during the factorization routine <i>p?dbtrf</i> and this is stored in <i>af</i> . If a linear system is to be solved using <i>p?dbtrf</i> after the factorization routine, <i>af</i> must not be altered after the factorization.
<i>work</i>	On exit, <i>work</i> (1) contains the minimal <i>lwork</i> .
<i>info</i>	(local). INTEGER. If <i>info</i> = 0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?dttrsv

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by p?dttrsv.

Syntax

```
call psdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
lwf, work, lwork, info)

call pddttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
lwf, work, lwork, info)

call pcdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
lwf, work, lwork, info)

call pzdttrsv(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af,
lwf, work, lwork, info)
```

Description

This routine solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$ or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ for real flavors; $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal matrix factor produced by the Gaussian elimination code PS@ (dom_pre) TTRF and is stored in $A(1:n, ja:ja+n-1)$ and af .

The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to $uplo$, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter $trans$.

Routine p?dttrf must be called first.

Input Parameters

uplo (global) CHARACTER.
 If $uplo='U'$, the upper triangle of $A(1:n, ja:ja+n-1)$ is stored,
 if $uplo = 'L'$, the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

trans (global) CHARACTER.
 If *trans* = 'N', solve with $A(1:n, ja:ja+n-1)$,
 if *trans* = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.

n (global) INTEGER. The order of the distributed submatrix A ; ($n \geq 0$).

nrhs (global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$. ($nrhs \geq 0$).

dl (local).
 REAL for psdttrsv
 DOUBLE PRECISION for pddttrsv
 COMPLEX for pcdttrsv
 COMPLEX*16 for pzdttrsv.
 Pointer to local part of global vector storing the lower diagonal of the matrix.
 Globally, *dl*(1) is not referenced, and *dl* must be aligned with *d*.
 Must be of size $\geq \text{desca}(nb\_)$.

d (local).
 REAL for psdttrsv
 DOUBLE PRECISION for pddttrsv
 COMPLEX for pcdttrsv
 COMPLEX*16 for pzdttrsv.
 Pointer to local part of global vector storing the main diagonal of the matrix.

du (local).
 REAL for psdttrsv
 DOUBLE PRECISION for pddttrsv
 COMPLEX for pcdttrsv
 COMPLEX*16 for pzdttrsv.
 Pointer to local part of global vector storing the upper diagonal of the matrix.
 Globally, *du*(*n*) is not referenced, and *du* must be aligned with *d*.

<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local). INTEGER array of DIMENSION (<i>dlen_</i>). if 1d type (<i>dtype_a</i> = 501 or 502), <i>dlen</i> ≥ 7; if 2d type (<i>dtype_a</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdttrsv DOUBLE PRECISION for pddttrsv COMPLEX for pcdttrsv COMPLEX*16 for pzdttrsv. Pointer into the local memory to an array of local lead DIMENSION <i>lld_b</i> ≥ <i>nb</i> . On entry, this array contains the local pieces of the right-hand sides <i>B</i> (<i>ib</i> : <i>ib</i> + <i>n</i> -1, 1 : <i>nrhs</i>).
<i>ib</i>	(global). INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local). INTEGER array of DIMENSION (<i>dlen_</i>). if 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; if 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping <i>B</i> to memory.
<i>laf</i>	(local). INTEGER. Size of user-input Auxiliary Filling space <i>af</i> . <i>laf</i> must be ≥ 2*(<i>nb</i> +2). If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local). REAL for psdttrsv DOUBLE PRECISION for pddttrsv COMPLEX for pcdttrsv

COMPLEX*16 for pzdttrsv.
 Temporary workspace. This space may be overwritten in
 between calls to routines.
work must be the size given in *lwork*.
lwork (local or global). INTEGER.
 Size of user-input workspace *work*. If *lwork* is too small,
 the minimal acceptable size will be returned in *work*(1) and
 an error code is returned.
 $lwork \geq 10 * npcol + 4 * nrhs$.

Output Parameters

dl (local).
 On exit, this array contains information containing the
 factors of the matrix.

d On exit, this array contains information containing the
 factors of the matrix. Must be of size $\geq desca(nb\_)$.

b On exit, this contains the local piece of the solutions
 distributed matrix X.

af (local).
 REAL for psdttrsv
 DOUBLE PRECISION for pddttrsv
 COMPLEX for pcdttrsv
 COMPLEX*16 for pzdttrsv.
 Auxiliary Filling Space. Filling is created during the
 factorization routine p?dttrf and this is stored in *af*. If a
 linear system is to be solved using p?dttrs after the
 factorization routine, *af* must not be altered after the
 factorization.

work On exit, *work*(1) contains the minimal *lwork*.

info (local). INTEGER.
 If *info*=0, the execution is successful.
 if *info*< 0: If the *i*-th argument is an array and the *j*-entry
 had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th
 argument is a scalar and had an illegal value, then *info* =
 -*i*.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

```

```

Description

This routine reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:
 $Q^* \text{sub}(A) P = B$.

If $m \geq n$, B is the upper bidiagonal; if $m < n$, B is the lower bidiagonal.

Input Parameters

m	(global) INTEGER. The number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for psgebd2 DOUBLE PRECISION for pdgebd2 COMPLEX for pcgebd2 COMPLEX*16 for pzgebd2. Pointer into the local memory to an array of DIMENSION(lld_a , $LOCc(ja+n-1)$). On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for psgebd2 DOUBLE PRECISION for pdgebd2 COMPLEX for pcgebd2 COMPLEX*16 for pzgebd2. This is a workspace array of DIMENSION (<i>lwork</i>).
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \max(m_{pa0}, n_{qa0})$, where $nb = mb\_a = nb\_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc\_a, nprow)$, $iacol = \text{indxg2p}(ja, nb, mycol, csrc\_a, npcol)$, $mpa0 = \text{numroc}(m+iroffa, nb, myrow, iarow, nprow)$, $nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol, npcol)$. <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	(local). On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix <i>B</i> ; the elements below the diagonal, with the array <i>tauq</i> ,

represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array *taup*, represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array *tauq*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array *taup*, represent the orthogonal matrix P as a product of elementary reflectors. See *Applications Notes* below.

d

(local)

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Array, DIMENSION $LOCc(ja+\min(m,n)-1)$ if $m \geq n$;
 $LOCr(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d(i) = a(i,i)$. *d* is tied to the distributed matrix A .

e

(local)

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

Array, DIMENSION $LOCc(ja+\min(m,n)-1)$ if $m \geq n$;
 $LOCr(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B :

if $m \geq n$, $e(i) = a(i, i+1)$ for $i = 1, 2, \dots, n-1$;

if $m < n$, $e(i) = a(i+1, i)$ for $i = 1, 2, \dots, m-1$.

e is tied to the distributed matrix A .

tauq

(local).

REAL for psgebd2

DOUBLE PRECISION for pdgebd2

COMPLEX for pcgebd2

COMPLEX*16 for pzgebd2.

taup Array, DIMENSION $LOCc(ja+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . *tauq* is tied to the distributed matrix A .

(local).
 REAL for psgebd2
 DOUBLE PRECISION for pdgebd2
 COMPLEX for pcgebd2
 COMPLEX*16 for pzgebd2.

work Array, DIMENSION $LOCr(ia+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix P . *taup* is tied to the distributed matrix A .

info On exit, *work*(1) returns the minimal and optimal *lwork*.
 (local)
 INTEGER.
 If *info* = 0, the execution is successful.
 if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i**100+*j*),
 if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1)*H(2)*\dots*H(n), \text{ and } P = G(1)*G(2)*\dots*G(n-1)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{uq} v v', \text{ and } G(i) = I - \tau_{up} u u',$$

where τ_{uq} and τ_{up} are real/complex scalars, and v and u are real/complex vectors. $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in

$$A(ia+i-ia+m-1, a+i-1);$$

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{uq} is stored in $TAUQ(ja+i-1)$ and τ_{up} in $TAUP(ia+i-1)$.

If $m < n$,

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i+1:ia+m-1, ja+i-1)$;

$u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$;

τ_{auq} is stored in $TAUQ(ja+i-1)$ and τ_{aup} in $TAUP(ia+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6$ ($m < n$):

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

p?gehd2

Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).

Syntax

call psgehd2($n, ilo, ihi, a, ia, ja, desca, \tau, work, lwork, info$)

call pdgehd2($n, ilo, ihi, a, ia, ja, desca, \tau, work, lwork, info$)

call pcgehd2($n, ilo, ihi, a, ia, ja, desca, \tau, work, lwork, info$)

call pzgehd2($n, ilo, ihi, a, ia, ja, desca, \tau, work, lwork, info$)

Description

This routine reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal/unitary similarity transformation: $Q' * \text{sub}(A) * Q = H$, where $\text{sub}(A) = A(ia+n-1:ia+n-1, ja+n-1:ja+n-1)$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed submatrix <i>A</i> . ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that $\text{sub}(A)$ is already upper triangular in rows $ia:ia+ilo-2$ and $ia+ihi:ia+n-1$ and columns $ja:ja+jlo-2$ and $ja+jhi:ja+n-1$. See <i>Application Notes</i> for further information. If $n \geq 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$.
<i>a</i>	(local). REAL for psgehd2 DOUBLE PRECISION for pdgehd2 COMPLEX for pcgehd2 COMPLEX*16 for pzgehd2. Pointer into the local memory to an array of $\text{DIMENSION}(lld\_a, LOCC(ja+n-1))$. On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, $\text{DIMENSION}(dlen\_)$. The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for psgehd2 DOUBLE PRECISION for pdgehd2 COMPLEX for pcgehd2 COMPLEX*16 for pzgehd2. This is a workspace array of $\text{DIMENSION}(lwork)$.
<i>lwork</i>	(local or global). INTEGER. The dimension of the array <i>work</i> .

lwork is local input and must be at least $lwork \geq nb + \max(npa0, nb)$, where $nb = mb\_a = nb\_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc\_a, nprow)$, $npa0 = \text{numroc}(ihi+iroffa, nb, myrow, iarow, nprow)$.

indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pserbla*.

Output Parameters

<i>a</i>	(local). On exit, the upper triangle and the first subdiagonal of sub(<i>A</i>) are overwritten with the upper Hessenberg matrix <i>H</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors. (see <i>Application Notes</i> below).
<i>tau</i>	(local). REAL for <i>psgehd2</i> DOUBLE PRECISION for <i>pdgehd2</i> COMPLEX for <i>pcgehd2</i> COMPLEX*16 for <i>pzgehd2</i> . Array, DIMENSION <i>LOCc</i> (<i>ja+n-2</i>) The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements <i>ja:ja+ilo-2</i> and <i>ja+ihi:ja+n-2</i> of <i>tau</i> are set to zero. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local).INTEGER. If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(ilo+1)*\dots*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i)=0$, $v(i+1)=1$ and $v(ihi+1:n)=0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)$, and τ in $\tau(ja+ilo+i-2)$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ & a & h & h & h & h & a \\ & h & h & h & h & h & h \\ & v2 & h & h & h & h & h \\ & v2 & v3 & h & h & h & h \\ & v2 & v3 & v4 & h & h & h \\ & & & & & & a \end{bmatrix}$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?gelq2

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

This routine computes an LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L^*Q$.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for psgelq2 DOUBLE PRECISION for pdgelq2 COMPLEX for pcgelq2 COMPLEX*16 for pzgelq2. Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOcc(ja+n-1))</code> . On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for psgelq2 DOUBLE PRECISION for pdgelq2 COMPLEX for pcgelq2 COMPLEX*16 for pzgelq2. This is a workspace array of <code>DIMENSION(lwork)</code> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> .

lwork is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$,

where $irow = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$,

$iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$,
 $mp0 = \text{numroc}(m+irow, mb\_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcot)$,
 indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcot$ can be determined by calling the subroutine `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

(local).

On exit, the elements on and below the diagonal of sub(*A*) contain the m by $\min(m, n)$ lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau

(local).

REAL for `psgelq2`

DOUBLE PRECISION for `pdgelq2`

COMPLEX for `pcgelq2`

COMPLEX*16 for `pzgelq2`.

Array, DIMENSION $LOCr(ia+\min(m, n)-1)$. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix *A*.

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local).INTEGER. If *info* = 0, the execution is successful. if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia)$ for real flavors, $Q = (H(ia+k-1))^H * (H(ia+k-2))^H \dots * (H(ia))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ (for real flavors) or $\text{conjg}(v(i+1:n))$ (for complex flavors) is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and τ in $TAU(ia+i-1)$.

p?geql2

Computes a QL factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine computes a QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$.

Input Parameters

m (global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

n (global) INTEGER.
The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

a (local).
REAL for psgeql2
DOUBLE PRECISION for pdgeql2
COMPLEX for pcgeql2
COMPLEX*16 for pzgeql2.
Pointer into the local memory to an array of DIMENSION (*lld_a*, *LOCc* (*ja*+*n*-1)).
On entry, this array contains the local pieces of the *m*-by-*n* distributed matrix $\text{sub}(A)$ which is to be factored.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*.

work (local).
REAL for psgeql2
DOUBLE PRECISION for pdgeql2
COMPLEX for pcgeql2
COMPLEX*16 for pzgeql2.
This is a workspace array of DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$,
where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npc0l)$,
 $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npc0l)$,

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	(local). On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n-by-n lower triangular matrix L; if $m \leq n$, the elements on and below the $(n-m)$-th superdiagonal contain the m-by-n lower trapezoidal matrix L; the remaining elements, with the array <code>tau</code>, represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local). REAL for <code>psgeql2</code> DOUBLE PRECISION for <code>pdgeql2</code> COMPLEX for <code>pcgeql2</code> COMPLEX*16 for <code>pzgeql2</code>. Array, DIMENSION <code>LOCc(ja+n-1)</code>. This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix A.
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local). INTEGER. If <code>info = 0</code>, the execution is successful. if <code>info < 0</code>: If the i-th argument is an array and the j-entry had an illegal value, then <code>info = - (i*100+j)</code>, if the i-th argument is a scalar and had an illegal value, then <code>info = -i</code>.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $TAU(ja+n-k+i-1)$.

p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

This routine computes a QR factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * R$.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for psgeqr2

DOUBLE PRECISION for pdgeqr2
 COMPLEX for pcgeqr2
 COMPLEX*16 for pzgeqr2.
 Pointer into the local memory to an array of DIMENSION
 (*lld_a*, *LOCc* (*ja+n-1*)).
 On entry, this array contains the local pieces of the *m*-by-*n*
 distributed matrix sub(*A*) which is to be factored.

ia, *ja* (global) INTEGER. The row and column indices in the global
 array *a* indicating the first row and the first column of the
 submatrix *A*, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The
 array descriptor for the distributed matrix *A*.

work (local).
 REAL for psgeqr2
 DOUBLE PRECISION for pdgeqr2
 COMPLEX for pcgeqr2
 COMPLEX*16 for pzgeqr2.
 This is a workspace array of DIMENSION (*lwork*).

lwork (local or global). INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$,
 where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$,
 $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcot)$.
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*,
mycol, *nprow*, and *npcol* can be determined by calling the
 subroutine *blacs_gridinfo*.
 If *lwork* = -1, then *lwork* is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by *pxerbla*.

Output Parameters

<i>a</i>	(local). On exit, the elements on and above the diagonal of $\text{sub}(A)$ contain the $\min(m,n)$ by n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local). REAL for psgeqr2 DOUBLE PRECISION for pdgeqr2 COMPLEX for pcgeqr2 COMPLEX*16 for pzgeqr2. Array, DIMENSION $\text{LOCc}(ja+\min(m,n)-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local). INTEGER. If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(j) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and τ in $TAU(ja+i-1)$.

p?gerq2

Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Description

This routine computes an RQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A)$
 $= A(ia:ia+m-1, ja:ja+n-1) = R*Q$.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for psgerq2 DOUBLE PRECISION for pdgerq2 COMPLEX for pcgerq2 COMPLEX*16 for pzgerq2. Pointer into the local memory to an array of DIMENSION ($lld\_a, LOCC(ja+n-1)$). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix A.

work (local).
 REAL for *psgerq2*
 DOUBLE PRECISION for *pdgerq2*
 COMPLEX for *pcgerq2*
 COMPLEX*16 for *pzgerq2*.
 This is a workspace array of DIMENSION (*lwork*).

lwork (local or global). INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where
 $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npc0l)$,
 $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npc0l)$,
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npc0l* can be determined by calling the subroutine *blacs_gridinfo*.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a (local).
 On exit,
 if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ;

if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

τ

(local).

REAL for psgqrq2

DOUBLE PRECISION for pdgqrq2

COMPLEX for pcgqrq2

COMPLEX*16 for pzgqrq2.

Array, DIMENSION $LOCr(ia+m-1)$. This array contains the scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .

$work$

On exit, $work(1)$ returns the minimal and optimal $lwork$.

$info$

(local). INTEGER.

If $info = 0$, the execution is successful.

if $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$ for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H * \dots * (H(ia+k-1))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$,

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ for real flavors or $\text{conjg}(v(1:n-k+i-1))$ for complex flavors is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $TAU(ia+m-k+i-1)$.

p?getf2

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

Syntax

```
call psgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pdgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pcgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pzgetf2(m, n, a, ia, ja, desca, ipiv, info)
```

Description

This routine computes an LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using partial pivoting with row interchanges.

The factorization has the form $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($nb\_a - \text{mod}(ja-1, nb\_a) \geq n \geq 0$).
a	(local). REAL for psgetf2 DOUBLE PRECISION for pdgetf2 COMPLEX for pcgetf2 COMPLEX*16 for pzgetf2. Pointer into the local memory to an array of DIMENSION(lld_a , $LOCc(ja+n-1)$).

On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*.

Output Parameters

ipiv (local). INTEGER.
Array, DIMENSION ($\text{LOCr}(m\_a) + mb\_a$). This array contains the pivoting information. $ipiv(i) \rightarrow$ The global row that local row *i* was swapped with. This array is tied to the distributed matrix *A*.

info (local). INTEGER.
If *info* = 0: successful exit.
If *info* < 0:

- if the *i*-th argument is an array and the *j*-entry had an illegal value, then $info = -(i*100+j)$,
- if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.

If *info* > 0: If $info = k$, $u(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor *u* is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?labrd

Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

```
call pslabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

```
call pdlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

```
call pclabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

```
call pzlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx,
y, iy, jy, descy, work)
```

Description

This routine reduces the first nb rows and columns of a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q'^* A * P$, and returns the matrices X and Y necessary to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $m \geq n$, $\text{sub}(A)$ is reduced to upper bidiagonal form; if $m < n$, $\text{sub}(A)$ is reduced to lower bidiagonal form.

This is an auxiliary routine called by [p?gebrd](#).

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

<i>nb</i>	(global) INTEGER. The number of leading rows and columns of sub(<i>A</i>) to be reduced.
<i>a</i>	(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd. Pointer into the local memory to an array of DIMENSION(<i>lld_a</i> , <i>LOC(ja+n-1)</i>). On entry, this array contains the local pieces of the general distributed matrix sub(<i>A</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION(<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix sub(<i>X</i>), respectively.
<i>descx</i>	(global and local) INTEGER array, DIMENSION(<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the global array <i>y</i> indicating the first row and the first column of the submatrix sub(<i>Y</i>), respectively.
<i>descy</i>	(global and local) INTEGER array, DIMENSION(<i>dlen_</i>). The array descriptor for the distributed matrix <i>Y</i> .
<i>work</i>	(local). REAL for pslabrd DOUBLE PRECISION for pdlabrd COMPLEX for pclabrd COMPLEX*16 for pzlabrd Workspace array, DIMENSION(<i>lwork</i>) $lwork \geq nb\_a + nq$, with $nq = \text{numroc}(n + \text{mod}(ia-1, nb\_y), nb\_y, mycol, iacol, npcol)$

`iacol = indxg2p (ja, nb_a, mycol, csrc_a, npcol)`
`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`,
`mycol`, `nprow`, and `npcol` can be determined by calling the
subroutine `blacs_gridinfo`.

Output Parameters

- a** (local)
On exit, the first `nb` rows and columns of the matrix are overwritten; the rest of the distributed matrix `sub(A)` is unchanged.
If $m \geq n$, elements on and below the diagonal in the first `nb` columns, with the array `tauq`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first `nb` rows, with the array `taup`, represent the orthogonal/unitary matrix P as a product of elementary reflectors.
If $m < n$, elements below the diagonal in the first `nb` columns, with the array `tauq`, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first `nb` rows, with the array `taup`, represent the orthogonal/unitary matrix P as a product of elementary reflectors. See *Application Notes* below.
- d** (local).
REAL for `pslabrd`
DOUBLE PRECISION for `pdlabrd`
COMPLEX for `pclabrd`
COMPLEX*16 for `pzlabrd`
Array, DIMENSION `LOCr(ia+min(m,n)-1)` if $m \geq n$;
`LOCc(ja+min(m,n)-1)` otherwise. The distributed diagonal elements of the bidiagonal distributed matrix B :
 $d(i) = A(ia+i-1, ja+i-1)$.
`d` is tied to the distributed matrix A .
- e** (local).
REAL for `pslabrd`
DOUBLE PRECISION for `pdlabrd`
COMPLEX for `pclabrd`

COMPLEX*16 for pzlabrd

Array, DIMENSION $LOCr(ia+\min(m,n)-1)$ if $m \geq n$;
 $LOCc(ja+\min(m,n)-2)$ otherwise. The distributed
off-diagonal elements of the bidiagonal distributed matrix
 B :

if $m \geq n$, $E(i) = A(ia+i-1, ja+i)$ for $i = 1, 2, \dots, n-1$;
if $m < n$, $E(i) = A(ia+i, ja+i-1)$ for $i = 1, 2, \dots, m-1$.
 e is tied to the distributed matrix A .

τ_{auq}, τ_{aup} (local).
REAL for pslabrd
DOUBLE PRECISION for pdlabrd
COMPLEX for pclabrd
COMPLEX*16 for pzlabrd
Array DIMENSION $LOCc(ja+\min(m,n)-1)$ for τ_{auq} ,
DIMENSION $LOCr(ia+\min(m,n)-1)$ for τ_{aup} . The scalar
factors of the elementary reflectors which represent the
orthogonal/unitary matrix Q for τ_{auq} , P for τ_{aup} . τ_{auq} and
 τ_{aup} are tied to the distributed matrix A . See *Application
Notes* below.

x (local)
REAL for pslabrd
DOUBLE PRECISION for pdlabrd
COMPLEX for pclabrd
COMPLEX*16 for pzlabrd
Pointer into the local memory to an array of DIMENSION
 (lld_x, nb) . On exit, the local pieces of the distributed
 m -by- nb matrix $X(ix:ix+m-1, jx:jx+nb-1)$ required to
update the unreduced part of $\text{sub}(A)$.

y (local).
REAL for pslabrd
DOUBLE PRECISION for pdlabrd
COMPLEX for pclabrd
COMPLEX*16 for pzlabrd

Pointer into the local memory to an array of `DIMENSION` (`lld_y, nb`). On exit, the local pieces of the distributed n -by- nb matrix $Y(iy:iy+n-1, jy:jy+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \text{tauq} * v * v', \text{ and } G(i) = I - \text{taup} * u * u',$$

where tauq and taup are real/complex scalars, and v and u are real/complex vectors.

If $m \geq n$, $v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$; tauq is stored in $\text{TAUQ}(ja+i-1)$ and taup in $\text{TAUP}(ia+i-1)$.

If $m < n$, $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$; tauq is stored in $\text{TAUQ}(ja+i-1)$ and taup in $\text{TAUP}(ia+i-1)$. The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are necessary, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $\text{sub}(A) := \text{sub}(A) - V * Y' - X * U'$. The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $nb = 2$:

$m = 6$ and $n = 5 (m > n)$:

$$\begin{bmatrix} 1 & 1 & v1 & u1 & u1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

$m = 5$ and $n = 6 (m < n)$:

$$\begin{bmatrix} 1 & u1 & u1 & u1 & u1 & u1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

```
call pslacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pdlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pclacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pzlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
```

Description

This routine estimates the 1-norm of a square, real/unitary distributed matrix *A*. Reverse communication is used for evaluating matrix-vector products. *x* and *v* are aligned with the distributed matrix *A*, this information is implicitly contained within *iv*, *ix*, *descv*, and *descx*.

Input Parameters

<i>n</i>	(global).INTEGER. The length of the distributed vectors <i>v</i> and <i>x</i> . $n \geq 0$.
<i>v</i>	(local). REAL for pslacon DOUBLE PRECISION for pdlacon COMPLEX for pclacon COMPLEX*16 for pzlacon. Pointer into the local memory to an array of DIMENSION <i>LOCr</i> ($n + \text{mod}(iv-1, mb\_v)$). On the final return, $v = a * w$, where $est = \text{norm}(v) / \text{norm}(w)$ (<i>w</i> is not returned).
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix <i>V</i> , respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>x</i>	(local). REAL for pslacon

DOUBLE PRECISION for pdlacon
 COMPLEX for pclacon
 COMPLEX*16 for pzlacon.
 Pointer into the local memory to an array of DIMENSION
 $LOCr(n+mod(ix-1, mb_x))$.

ix, jx (global) INTEGER. The row and column indices in the global array *x* indicating the first row and the first column of the submatrix *x*, respectively.

descx (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix X.

isgn (local). INTEGER.
 Array, DIMENSION $LOCr(n+mod(ix-1, mb_x))$. *isgn* is aligned with *x* and *v*.

kase (local). INTEGER.
 On the initial call to p?lacon, *kase* should be 0.

Output Parameters

x (local).
 On an intermediate return, X should be overwritten by A^*X , if *kase*=1, $A' * X$, if *kase*=2, p?lacon must be re-called with all the other parameters unchanged.

est (global). REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors

kase (local)
 INTEGER. On an intermediate return, *kase* is 1 or 2, indicating whether *x* should be overwritten by A^*X , or $A' * X$. On the final return from p?lacon, *kase* is again 0.

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

```
call pslaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
call pdlaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

Description

This routine looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by *h44*, *h33*, and *h43h34* to see if this process makes a subdiagonal negligible.

Input Parameters

<i>a</i>	(global). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb Array, DIMENSION (<i>desca</i> (<i>lld_</i>),*). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) INTEGER. The global location of the top of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>h44, h33, h43h34</i>	(global). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb These three values are for the double shift QR iteration.
<i>lwork</i>	(global) INTEGER. This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcol))$. Here <i>lcm</i> is least common multiple and <i>nprowxnpcol</i> is the logical grid size.

Output Parameters

<i>m</i>	(global). On exit, this yields the starting location of the <i>QR</i> double shift. This will satisfy: $1 \leq m \leq i-2$.
<i>buf</i>	(local). REAL for <i>pslaconsb</i> DOUBLE PRECISION for <i>pdlaconsb</i> Array of size <i>lwork</i> .
<i>lwork</i>	(global). On exit, <i>lwork</i> is the size of the work buffer.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

```
call pslacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Description

This routine copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, *p?lacp2* performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, a:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

p?lacp2 requires that only dimension of the matrix operands is distributed.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

	Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for pslacp2 DOUBLE PRECISION for pdlacp2 COMPLEX for pclacp2 COMPLEX*16 for pzlapc2. Pointer into the local memory to an array of <code>DIMENSION (lld_a, LOcc(ja+n-1))</code> . On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, <code>DIMENSION (dlen_)</code> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array, <code>DIMENSION (dlen_)</code> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	(local). REAL for pslacp2 DOUBLE PRECISION for pdlacp2 COMPLEX for pclacp2 COMPLEX*16 for pzlapc2.

Pointer into the local memory to an array of `DIMENSION` (`lld_b, LOCC(jb+n-1)`). This array contains on exit the local pieces of the distributed matrix `sub( B )` set as follows:
 if `uplo = 'U'`, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$,
 $1 \leq i \leq j, 1 \leq j \leq n$;
 if `uplo = 'L'`, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$,
 $j \leq i \leq m, 1 \leq j \leq n$;
 otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m, 1 \leq j \leq n$.

p?lACP3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

```
call pslACP3(m, i, a, desca, b, ldb, ii, jj, rev)
```

```
call pdlACP3(m, i, a, desca, b, ldb, ii, jj, rev)
```

Description

This is an auxiliary routine that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Input Parameters

<i>m</i>	(global) INTEGER. <i>m</i> is the order of the square submatrix that is copied. $m \geq 0$. Unchanged on exit.
<i>i</i>	(global) INTEGER. $A(i, i)$ is the global location that the copying starts from. Unchanged on exit.
<i>a</i>	(global). REAL for pslACP3 DOUBLE PRECISION for pdlACP3 Array, DIMENSION (<code>desca(lld_)</code> ,*). On entry, the parallel matrix to be copied into or from.

<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local). REAL for pslacp3 DOUBLE PRECISION for pdlacp3 Array, DIMENSION (<i>ldb</i> , <i>m</i>). If <i>rev</i> = 0, this is the global portion of the array <i>A</i> (<i>i</i> : <i>i+m-1</i> , <i>i</i> : <i>i+m-1</i>). If <i>rev</i> = 1, this is the unchanged on exit.
<i>ldb</i>	(local) INTEGER. The leading dimension of <i>B</i> .
<i>ii</i>	(global) INTEGER. By using <i>rev</i> 0 and 1, data can be sent out and returned again. If <i>rev</i> = 0, then <i>ii</i> is destination row index for the node(s) receiving the replicated <i>B</i> . If <i>ii</i> ≥ 0, <i>jj</i> ≥ 0, then node (<i>ii</i> , <i>jj</i>) receives the data. If <i>ii</i> = -1, <i>jj</i> ≥ 0, then all rows in column <i>jj</i> receive the data. If <i>ii</i> ≥ 0, <i>jj</i> = -1, then all cols in row <i>ii</i> receive the data. If <i>ii</i> = -1, <i>jj</i> = -1, then all nodes receive the data. If <i>rev</i> != 0, then <i>ii</i> is the source row index for the node(s) sending the replicated <i>B</i> .
<i>jj</i>	(global) INTEGER. Similar description as <i>ii</i> above.
<i>rev</i>	(global) INTEGER. Use <i>rev</i> = 0 to send global <i>A</i> into locally replicated <i>B</i> (on node (<i>ii</i> , <i>jj</i>)). Use <i>rev</i> != 0 to send locally replicated <i>B</i> from node (<i>ii</i> , <i>jj</i>) to its owner (which changes depending on its location in <i>A</i>) into the global <i>A</i> .

Output Parameters

<i>a</i>	(global). On exit, if <i>rev</i> = 1, the copied data. Unchanged on exit if <i>rev</i> = 0.
<i>b</i>	(local). If <i>rev</i> = 1, this is unchanged on exit.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call pslacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Description

This routine copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, `p?lacpy` performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

Input Parameters

<i>uplo</i>	(global). CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for <code>pslacpy</code> DOUBLE PRECISION for <code>pdlacpy</code> COMPLEX for <code>pclacpy</code>

	COMPLEX*16 for pzlapcy. Pointer into the local memory to an array of DIMENSION (lld_a, LOcc(ja+n-1)). On entry, this array contains the local pieces of the distributed matrix sub(A).
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix sub(A), respectively.
desca	(global and local) INTEGER array, DIMENSION (dlen_). The array descriptor for the distributed matrix A.
ib, jb	(global) INTEGER. The row and column indices in the global array B indicating the first row and the first column of sub(B) respectively.
descb	(global and local) INTEGER array, DIMENSION (dlen_). The array descriptor for the distributed matrix A.

Output Parameters

b	(local). REAL for pslapcy DOUBLE PRECISION for pdlapcy COMPLEX for pclapcy COMPLEX*16 for pzlapcy. Pointer into the local memory to an array of DIMENSION (lld_b, LOcc(jb+n-1)). This array contains on exit the local pieces of the distributed matrix sub(B) set as follows: if uplo = 'U', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq j, 1 \leq j \leq n$; if uplo = 'L', $B(ib+i-1, jb+j-1) = A(ia+i-1,$ $ja+j-1), j \leq i \leq m, 1 \leq j \leq n$; otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 \leq i \leq m,$ $1 \leq j \leq n$.

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

```
call pslaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pdlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pclaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pzlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

Description

This routine moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

n (global). INTEGER.
The order of the matrix *A*. $n \geq 0$.

zin (local).
REAL for pslaevswp
DOUBLE PRECISION for pdlaevswp
COMPLEX for pclaevswp
COMPLEX*16 for pzlaevswp. Array, DIMENSION (*ldzi*, *nvs*(*iam*)). The eigenvectors on input. Each eigenvector resides entirely in one process. Each process holds a contiguous set of *nvs*(*iam*) eigenvectors. The first eigenvector which the process holds is: sum for $i=[0, iam-1]$ of *nvs*(*i*).

ldzi (local)
INTEGER. The leading dimension of the *zin* array.

<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>z</i> , respectively.
<i>descz</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Z</i> .
<i>nvs</i>	(global) INTEGER. Array, DIMENSION(<i>nprocs</i> +1) <i>nvs</i> (<i>i</i>) = number of processes number of eigenvectors held by processes [0, <i>i</i> -1] <i>nvs</i> (1) = number of eigen vectors held by [0, 1 -1) = 0 <i>nvs</i> (<i>nprocs</i> +1)= number of eigen vectors held by [0, <i>nprocs</i>)= total number of eigenvectors.
<i>key</i>	(global) INTEGER. Array, DIMENSION (<i>n</i>). Indicates the actual index (after sorting) for each of the eigenvectors.
<i>rwork</i>	(local). REAL for <i>pslaevswp</i> DOUBLE PRECISION for <i>pdlaevswp</i> COMPLEX for <i>pclaevswp</i> COMPLEX*16 for <i>pzlaevswp</i> . Array, DIMENSION (<i>lrwork</i>).
<i>lrwork</i>	(local) INTEGER. Dimension of <i>work</i> .

Output Parameters

<i>z</i>	(local). REAL for <i>pslaevswp</i> DOUBLE PRECISION for <i>pdlaevswp</i> COMPLEX for <i>pclaevswp</i> COMPLEX*16 for <i>pzlaevswp</i> . Array, global DIMENSION (<i>n, n</i>), local DIMENSION (<i>descz</i> (<i>dlen_</i>), <i>nq</i>). The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of <i>nb</i> .

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

```
call pslahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pdlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pclahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
call pzlahrd(n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work)
```

Description

The routines reduces the first nb columns of a real general n -by- $(n-k+1)$ distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$ so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation $Q' * A * Q$. The routine returns the matrices V and T which determine Q as a block reflector $I - V * T * V'$, and also the matrix $Y = A * V * T$.

This is an auxiliary routine called by `p?gehrd`. In the following comments `sub(A)` denotes $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix <code>sub(A)</code> . $n \geq 0$.
k	(global) INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
nb	(global) INTEGER. The number of columns to be reduced.
a	(local). REAL for <code>pslahrd</code> DOUBLE PRECISION for <code>pdlahrd</code>

	COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , <i>LOCc</i> (<i>ja+n-k</i>)). On entry, this array contains the local pieces of the <i>n</i> -by- <i>(n-k+1)</i> general distributed matrix <i>A</i> (<i>ia:ia+n-1</i> , <i>ja:ja+n-k</i>).
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iy</i> , <i>jy</i>	(global) INTEGER. The row and column indices in the global array <i>Y</i> indicating the first row and the first column of the submatrix sub(<i>Y</i>), respectively.
<i>descy</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Y</i> .
<i>work</i>	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION (<i>nb</i>).

Output Parameters

<i>a</i>	(local). On exit, the elements on and above the <i>k</i> -th subdiagonal in the first <i>nb</i> columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the <i>k</i> -th subdiagonal, with the array <i>tau</i> , represent the matrix <i>Q</i> as a product of elementary reflectors. The other columns of <i>A</i> (<i>ia:ia+n-1</i> , <i>ja:ja+n-k</i>) are unchanged. (See <i>Application Notes</i> below.)
<i>tau</i>	(local) REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd

COMPLEX*16 for pzlahrd.
 Array, DIMENSION $LOCc(ja+n-2)$. The scalar factors of the elementary reflectors (see *Application Notes* below). τ is tied to the distributed matrix A .

t (local) REAL for pslahrd
 DOUBLE PRECISION for pdlahrd
 COMPLEX for pclahrd
 COMPLEX*16 for pzlahrd.
 Array, DIMENSION (nb_a, nb_a) The upper triangular matrix T .

y (local).
 REAL for pslahrd
 DOUBLE PRECISION for pdlahrd
 COMPLEX for pclahrd
 COMPLEX*16 for pzlahrd.
 Pointer into the local memory to an array of DIMENSION (lld_y, nb_a) . On exit, this array contains the local pieces of the n -by- nb distributed matrix Y . $lld\_y \geq LOCr(ia+n-1)$.

Application Notes

The matrix Q is represented as a product of nb elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $A(ia+i+k:ia+n-1, ja+i-1)$, and τ in $TAU(ja+i-1)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form: $A(ia:ia+n-1, ja:ja+n-k) := (I - V * T * V') * (A(ia:ia+n-1, ja:ja+n-k) - Y * V')$. The contents of $A(ia:ia+n-1, ja:ja+n-k)$ on exit are illustrated by the following example with $n = 7$, $k = 3$, and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix $A(ia:ia+n-1, ja:ja+n-k)$, h denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(i)$.

p?laiect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).

Syntax

```
void pslaieict(float *sigma, int *n, float *d, int *count);
void pdlaieictb(float *sigma, int *n, float *d, int *count);
void pdlaieictl(float *sigma, int *n, float *d, int *count);
```

Description

This routine computes the number of negative eigenvalues of $(A - \sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real routine `pslaieict` is assumed to be bit 32. Double precision routines `pdlaieictb` and `pdlaieictl` differ in the order of the double precision word storage and, consequently, in the signbit location. For `pdlaieictb`, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For `pdlaieictl`, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

sigma Real for `pslaiect`
DOUBLE PRECISION for `pdlaiectb`/`pdlaiectl`.
The shift. `p?laiect` finds the number of eigenvalues less than equal to *sigma*.

n INTEGER. The order of the tridiagonal matrix *T*. $n \geq 1$.

d Real for `pslaiect`
DOUBLE PRECISION for `pdlaiectb`/`pdlaiectl`.
Array of DIMENSION $(2n - 1)$.
On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix *T*. These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of *T* are in the entries $d(1), d(3), \dots, d(2n-1)$, while the squares of the off-diagonal entries are $d(2), d(4), \dots, d(2n-2)$. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

Output Parameters

n INTEGER. The count of the number of eigenvalues of *T* less than or equal to *sigma*.

p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

Syntax

```
val = pslange(norm, m, n, a, ia, ja, desca, work)
val = pdlange(norm, m, n, a, ia, ja, desca, work)
val = pclange(norm, m, n, a, ia, ja, desca, work)
val = pzlange(norm, m, n, a, ia, ja, desca, work)
```

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	(global) CHARACTER. Specifies what value is returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A, it s not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>m</i>	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, <code>p?lange</code> is set to zero. $m \geq 0$.
<i>n</i>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, <code>p?lange</code> is set to zero. $n \geq 0$.
<i>a</i>	(local). Real for <code>pslange</code> DOUBLE PRECISION for <code>pdlange</code> COMPLEX for <code>pclange</code> COMPLEX*16 for <code>pzlange</code>. Pointer into the local memory to an array of DIMENSION (<code>lld_a</code>, <code>LOCc(ja+n-1)</code>) containing the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix A.

work (local).
 Real for pslange
 DOUBLE PRECISION for pdlange
 COMPLEX for pclange
 COMPLEX*16 for pzlange.
 Array DIMENSION (*lwork*).
lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),
*nq*0 if *norm* = '1', 'O' or 'o',
*mp*0 if *norm* = 'I' or 'i',
 0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
 where
iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),
iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),
iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),
*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),
*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),
 indxg2p and numroc are ScaLAPACK tool routines; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

val The value returned by the routine.

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

```
val = pslanhs(norm, n, a, ia, ja, desca, work)
val = pdlanhs(norm, n, a, ia, ja, desca, work)
val = pclanhs(norm, n, a, ia, ja, desca, work)
val = pzlanhs(norm, n, a, ia, ja, desca, work)
```

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, p?lanhs is set to zero. $n \geq 0$.
<i>a</i>	(local). Real for pslanhs DOUBLE PRECISION for pdlanhs COMPLEX for pclanhs

COMPLEX*16 for pzlanhs.
 Pointer into the local memory to an array of
 DIMENSION(*lld_a*, *LOCc(ja+n-1)*) containing the local
 pieces of the distributed matrix sub(*A*).

ia, ja (global) INTEGER.
 The row and column indices in the global array *A* indicating
 the first row and the first column of the submatrix sub(*A*),
 respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen_*). The
 array descriptor for the distributed matrix *A*.

work (local).
 Real for pslanhs
 DOUBLE PRECISION for pdlanhs
 COMPLEX for pclanhs
 COMPLEX*16 for pzlanh.
 Array, DIMENSION (*lwork*).
lwork ≥ 0 if *norm* = 'M' or 'm' (not referenced),
*nq*0 if *norm* = '1', 'O' or 'o',
*mp*0 if *norm* = 'I' or 'i',
 0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
 where
iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),
iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprow*),
iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csrc_a*, *npcol*),
*mp*0 = numroc(*m*+*iroffa*, *mb_a*, *myrow*, *iarow*, *nprow*),
*nq*0 = numroc(*n*+*icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),
 indxg2p and numroc are ScaLAPACK tool routines; *myrow*,
mycol, *nprow*, and *npcol* can be determined by calling the
 subroutine *blacs_gridinfo*.

Output Parameters

val The value returned by the fuction.

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

```
val = pslansy(norm, uplo, n, a, ia, ja, desca, work)
val = pdlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclansy(norm, uplo, n, a, ia, ja, desca, work)
val = pzlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclanhe(norm, uplo, n, a, ia, ja, desca, work)
val = pzlanhe(norm, uplo, n, a, ia, ja, desca, work)
```

Description

The routines return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	(global) CHARACTER. Specifies what value is returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A, it s not a matrix norm. = '1' or 'O' or 'o': $val = \text{norml}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper triangular part of $\text{sub}(A)$ is referenced,

= 'L': Lower triangular part of sub(A) is referenced.

n (global) INTEGER.
The number of columns to be operated on i.e the number of columns of the distributed submatrix sub(A). When $n = 0$, p?lansy is set to zero. $n \geq 0$.

a (local).
Real for pslansy
DOUBLE PRECISION for pdlansy
COMPLEX for pclansy, pplanhe
COMPLEX*16 for pzlanse, pzlanhe.
Pointer into the local memory to an array of DIMENSION (lld_a, LOCC(ja+n-1)) containing the local pieces of the distributed matrix sub(A).
If uplo = 'U', the leading n -by- n upper triangular part of sub(A) contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If uplo = 'L', the leading n -by- n lower triangular part of sub(A) contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of sub(A) is not referenced.

ia, ja (global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix sub(A), respectively.

desca (global and local) INTEGER array, DIMENSION (dlen_). The array descriptor for the distributed matrix A.

work (local).
Real for pslansy
DOUBLE PRECISION for pdlansy
COMPLEX for pclansy, pplanhe
COMPLEX*16 for pzlanse, pzlanhe.
Array DIMENSION (lwork).
 $lwork \geq 0$ if norm = 'M' or 'm' (not referenced),
 $2*nq0+np0+ldw$ if norm = '1', 'O' or 'o', 'I' or 'i',
where ldw is given by:
if(nprow.ne.npcol) then
ldw = mb_a*ceil(ceil(np0/mb_a)/(lcm/nprow))
else

```
ldw = 0
end if
0 if norm = 'F', 'f', 'E' or 'e' (not referenced),
where lcm is the least common multiple of nprow and
npcol, lcm = ilcm( nprow, npcol ) and ceil denotes
the ceiling operation (iceil).
iroffa = mod(ia-1, mb_a ), icoffa = mod( ja-1, nb_a),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),
mp0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nq0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol),
indxg2p and numroc are ScaLAPACK tool functions; myrow,
mycol, nprow, and npcol can be determined by calling the
subroutine blacs_gridinfo.
```

Output Parameters

val The value returned by the routine.

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

```
val = pslantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pdlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pclantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pzlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
```

Description

The routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix *sub*(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1).

Input Parameters

<i>norm</i>	(global) CHARACTER. Specifies what value is returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A, it is not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper trapezoidal, = 'L': Lower trapezoidal. Note that $\text{sub}(A)$ is triangular instead of trapezoidal if $m = n$.
<i>diag</i>	(global). CHARACTER. Specifies whether the distributed matrix $\text{sub}(A)$ has unit diagonal. = 'N': Non-unit diagonal. = 'U': Unit diagonal.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, <code>p?lantr</code> is set to zero. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, <code>p?lantr</code> is set to zero. $n \geq 0$.
<i>a</i>	(local). Real for <code>pslantr</code> DOUBLE PRECISION for <code>pdlantr</code> COMPLEX for <code>pclantr</code> COMPLEX*16 for <code>pzlantr</code>.

Pointer into the local memory to an array of
`DIMENSION(11d_a, LOCc(ja+n-1))` containing the local
pieces of the distributed matrix `sub(A)`.

`ia, ja` (global) INTEGER.
The row and column indices in the global array `a` indicating
the first row and the first column of the submatrix `sub(A)`,
respectively.

`desca` (global and local) INTEGER array, `DIMENSION(dlen_)`. The
array descriptor for the distributed matrix `A`.

`work` (local).
Real for `pslantr`
DOUBLE PRECISION for `pdlantr`
COMPLEX for `pclantr`
COMPLEX*16 for `pzlantr`.
Array `DIMENSION(lwork)`.
`lwork ≥ 0` if `norm = 'M' or 'm'` (not referenced),
`nq0` if `norm = '1', 'O' or 'o'`,
`mp0` if `norm = 'I' or 'i'`,
`0` if `norm = 'F', 'f', 'E' or 'e'` (not referenced),
where `lcm` is the least common multiple of `nprow` and `npcol`
`lcm = ilcm(nprow, npcol)` and `ceil` denotes the ceiling
operation (`iceil`).
`iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1,`
`nb_a),`
`iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),`
`iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),`
`mp0 = numroc(m+iroffa, mb_a, myrow, iarow,`
`nprow),`
`nq0 = numroc(n+icoffa, nb_a, mycol, iacol,`
`npcol),`
`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow,`
`mycol, nprow,` and `npcol` can be determined by calling the
subroutine `blacs_gridinfo`.

Output Parameters

`val` The value returned by the routine.

p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

```
call pslapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)

call pdlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)

call pclapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)

call pzlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp,
descip, iwork)
```

Description

This routine applies either P (permutation matrix indicated by *ipiv*) or $\text{inv}(P)$ to a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix A . This routine will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $\text{sub}(A)$, pass *rowcol*='C' and *pivroc*='C'.

Input Parameters

<i>direc</i>	(global) CHARACTER*1. Specifies in which order the permutation is applied: = 'F' (Forward). Applies pivots forward from top of matrix. Computes $P * \text{sub}(A)$. = 'B' (Backward). Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) * \text{sub}(A)$.
<i>rowcol</i>	(global) CHARACTER*1. Specifies if the rows or columns are to be permuted: = 'R' Rows will be permuted, = 'C' Columns will be permuted.

<i>pivroc</i>	(global) CHARACTER*1. Specifies whether <i>ipiv</i> is distributed over a process row or column: = 'R' <i>ipiv</i> is distributed over a process row, = 'C' <i>ipiv</i> is distributed over a process column.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>A</i>). When $m = 0$, <i>p?lapiv</i> is set to zero. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(<i>A</i>). When $n = 0$, <i>p?lapiv</i> is set to zero. $n \geq 0$.
<i>a</i>	(local). Real for <i>pslapiv</i> DOUBLE PRECISION for <i>pdlapiv</i> COMPLEX for <i>pclapiv</i> COMPLEX*16 for <i>pzlapiv</i>. Pointer into the local memory to an array of DIMENSION(<i>lld_a</i>, <i>LOCc(ja+n-1)</i>) containing the local pieces of the distributed matrix sub(<i>A</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>ipiv</i>	(local). INTEGER. Array, DIMENSION (<i>lipiv</i>) ; when <i>rowcol</i>='R' or 'r': <i>lipiv</i> ≥ <i>LOCr(ia+m-1) + mb_a</i> if <i>pivroc</i>='C' or 'c', <i>lipiv</i> ≥ <i>LOCc(m + mod(jp-1, nb_p))</i> if <i>pivroc</i>='R' or 'r', and, when <i>rowcol</i>='C' or 'c':

$lipiv \geq LOCr(n + \text{mod}(ip-1, mb\_p))$ if $pivroc='C'$ or $'c'$,

$lipiv \geq LOCc(ja+n-1) + nb\_a$ if $pivroc='R'$ or $'r'$.

This array contains the pivoting information. $ipiv(i)$ is the global row (column), local row (column) i was swapped with. When $rowcol='R'$ or $'r'$ and $pivroc='C'$ or $'c'$, or $rowcol='C'$ or $'c'$ and $pivroc='R'$ or $'r'$, the last piece of this array of size mb_a (resp. nb_a) is used as workspace. In those cases, this array is tied to the distributed matrix A .

ip, jp

(global) INTEGER. The row and column indices in the global array P indicating the first row and the first column of the submatrix $\text{sub}(P)$, respectively.

$descip$

(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed vector $ipiv$.

$iwork$

(local). INTEGER.

Array, DIMENSION (ldw), where ldw is equal to the workspace necessary for transposition, and the storage of the transposed $ipiv$:

Let lcm be the least common multiple of $nprow$ and $npcol$.

```
If( rowcol.eq.'r' .and. pivroc.eq.'r') then
    If( nprow.eq. npcol) then
        ldw = LOCr( n_p + mod(jp-1, nb_p) ) + nb_p
    else
        ldw = LOCr( n_p + mod(jp-1, nb_p) ) +
        nb_p * ceil( ceil(LOCc(n_p)/nb_p) / (lcm/npcol) )
    end if
else if( rowcol.eq.'c' .and. pivroc.eq.'c') then
    if( nprow.eq.
npcol ) then
        ldw = LOCc( m_p + mod(ip-1, mb_p) ) + mb_p
    else
        ldw = LOCc( m_p + mod(ip-1, mb_p) ) +
        mb_p * ceil(ceil(LOCr(m_p)/mb_p) / (lcm/nprow) )
    end if
else
iwork is not referenced.
end if.
```

Output Parameters

a

(local).

On exit, the local pieces of the permuted distributed submatrix.

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.

Syntax

```
call pslaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pdlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pclaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pzlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
```

Description

This routine equilibrates a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using the row and scaling factors in the vectors r and c computed by p?geequ.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for pslaqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. Pointer into the local memory to an array of DIMENSION(lld_a , $LOCc(ja+n-1)$). On entry, this array contains the distributed matrix $\text{sub}(A)$.
ia, ja	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>r</i>	(local). REAL for pslaqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. Array, DIMENSION <i>LOCr(m_a)</i>. The row scale factors for sub(<i>A</i>). <i>r</i> is aligned with the distributed matrix <i>A</i>, and replicated across every process column. <i>r</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local). REAL for pslaqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. Array, DIMENSION <i>LOCc(n_a)</i>. The row scale factors for sub(<i>A</i>). <i>c</i> is aligned with the distributed matrix <i>A</i>, and replicated across every process column. <i>c</i> is tied to the distributed matrix <i>A</i>.
<i>rowcnd</i>	(local). REAL for pslaqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. The global ratio of the smallest $r(i)$ to the largest $r(i)$, $ia \leq i \leq ia+m-1$.
<i>colcnd</i>	(local). REAL for pslaqge DOUBLE PRECISION for pdlaqge COMPLEX for pclaqge COMPLEX*16 for pzlaqge. The global ratio of the smallest $c(i)$ to the largest $c(i)$, $ia \leq i \leq ia+n-1$.
<i>amax</i>	(global). REAL for pslaqge DOUBLE PRECISION for pdlaqge

COMPLEX for pclaqqe
 COMPLEX*16 for pzlaqqe.
 Absolute value of largest distributed submatrix entry.

Output Parameters

a (local).
 On exit, the equilibrated distributed matrix. See *equed* for the form of the equilibrated distributed submatrix.

equed (global) CHARACTER.
 Specifies the form of equilibration that was done.
 = 'N': No equilibration
 = 'R': Row equilibration, that is, $\text{sub}(A)$ has been pre-multiplied by $\text{diag}(r(ia:ia+m-1))$,
 = 'C': column equilibration, that is, $\text{sub}(A)$ has been post-multiplied by $\text{diag}(c(ja:ja+n-1))$,
 = 'B': Both row and column equilibration, that is, $\text{sub}(A)$ has been replaced by $\text{diag}(r(ia:ia+m-1)) * \text{sub}(A) * \text{diag}(c(ja:ja+n-1))$.

p?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.

Syntax

```
call pslaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pdlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pclaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pzlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
```

Description

This routine equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors *sr* and *sc*. The scaling factors are computed by p?poequ.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local). REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>sr</i>	(local) REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy.

	Array, DIMENSION $LOCr(m\_a)$. The scale factors for $A(ia:ia+m-1, ja:ja+n-1)$. sr is aligned with the distributed matrix A, and replicated across every process column. sr is tied to the distributed matrix A.
<i>sc</i>	(local) REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy. Array, DIMENSION $LOCc(m\_a)$. The scale factors for $A(ia:ia+m-1, ja:ja+n-1)$. sr is aligned with the distributed matrix A, and replicated across every process column. sr is tied to the distributed matrix A.
<i>scond</i>	(global). REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy. Ratio of the smallest $sr(i)$ (respectively $sc(j)$) to the largest $sr(i)$ (respectively $sc(j)$), with $ia \leq i \leq ia+n-1$ and $ja \leq j \leq ja+n-1$.
<i>amax</i>	(global). REAL for pslaqsy DOUBLE PRECISION for pdlaqsy COMPLEX for pclaqsy COMPLEX*16 for pzlaqsy. Absolute value of largest distributed submatrix entry.

Output Parameters

<i>a</i>	On exit, if <i>equed</i> = 'Y', the equilibrated matrix: $\text{diag}(sr(ia:ia+n-1)) * \text{sub}(A) * \text{diag}(sc(ja:ja+n-1))$.
<i>equed</i>	(global) CHARACTER*1. Specifies whether or not equilibration was done. = 'N': No equilibration.

```
= 'Y': Equilibration was done, that is, sub(A) has been
replaced by:
diag(sr(ia:ia+n-1))* sub(A) *
diag(sc(ja:ja+n-1)).
```

p?lared1d

Redistributes an array assuming that the input array, `bycol`, is distributed across rows and that all process columns contain the same copy of `bycol`.

Syntax

```
call pslared1d(n, ia, ja, desc, bycol, byall, work, lwork)
call pdlared1d(n, ia, ja, desc, bycol, byall, work, lwork)
```

Description

This routine redistributes a 1D array. It assumes that the input array `bycol` is distributed across rows and that all process column contain the same copy of `bycol`. The output array `byall` is identical on all processes and contains the entire array.

Input Parameters

`np` = Number of local rows in `bycol()`

`n` (global). INTEGER.
The number of elements to be redistributed. $n \geq 0$.

`ia, ja` (global) INTEGER. `ia, ja` must be equal to 1.

`desc` (global and local) INTEGER array, DIMENSION 8. A 2D array descriptor, which describes `bycol`.

`bycol` (local).
REAL for `pslared1d`
DOUBLE PRECISION for `pdlared1d`
COMPLEX for `pclared1d`
COMPLEX*16 for `pzlared1d`.
Distributed block cyclic array global DIMENSION (n), local DIMENSION np . `bycol` is distributed across the process rows. All process columns are assumed to contain the same value.

work (local).
 REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlarred1d.
 DIMENSION (*lwork*). Used to hold the buffers sent from one process to another.

lwork (local)
 INTEGER. The size of the *work* array. $lwork \geq \text{numroc}(n, \text{desc}(\text{nb\_}), 0, 0, \text{npcol})$.

Output Parameters

byall (global). REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlarred1d.
 Global DIMENSION (*n*), local DIMENSION (*n*). *byall* is exactly duplicated on all processes. It contains the same values as *bycol*, but it is replicated across all processes rather than being distributed.

p?lared2d

*Redistributes an array assuming that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*.*

Syntax

```
call pslared2d(n, ia, ja, desc, byrow, byall, work, lwork)
call pdlared2d(n, ia, ja, desc, byrow, byall, work, lwork)
```

Description

This routine redistributes a 1D array. It assumes that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*. The output array *byall* will be identical on all processes and will contain the entire array.

Input Parameters

np = Number of local rows in *byrow*()

<i>n</i>	(global) INTEGER. The number of elements to be redistributed. $n \geq 0$.
<i>ia, ja</i>	(global) INTEGER. <i>ia, ja</i> must be equal to 1.
<i>desc</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). A 2D array descriptor, which describes <i>byrow</i> .
<i>byrow</i>	(local). REAL for <i>pslared2d</i> DOUBLE PRECISION for <i>pdlared2d</i> COMPLEX for <i>pclared2d</i> COMPLEX*16 for <i>pzlared2d</i> . Distributed block cyclic array global DIMENSION (<i>n</i>), local DIMENSION <i>np</i> . <i>bycol</i> is distributed across the process columns. All process rows are assumed to contain the same value.
<i>work</i>	(local). REAL for <i>pslared2d</i> DOUBLE PRECISION for <i>pdlared2d</i> COMPLEX for <i>pclared2d</i> COMPLEX*16 for <i>pzlared2d</i> . DIMENSION (<i>lwork</i>). Used to hold the buffers sent from one process to another.
<i>lwork</i>	(local).INTEGER. The size of the <i>work</i> array. $lwork \geq \text{numroc}(n, \text{desc}(nb\_), 0, 0, npcol)$.

Output Parameters

<i>byall</i>	(global). REAL for <i>pslared2d</i> DOUBLE PRECISION for <i>pdlared2d</i> COMPLEX for <i>pclared2d</i> COMPLEX*16 for <i>pzlared2d</i> . Global DIMENSION(<i>n</i>), local DIMENSION (<i>n</i>). <i>byall</i> is exactly duplicated on all processes. It contains the same values as <i>bycol</i> , but it is replicated across all processes rather than being distributed.

p?larf

Applies an elementary reflector to a general rectangular matrix.

Syntax

```
call pslarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

This routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global). CHARACTER. = 'L': form $Q * \text{sub}(C)$, = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>v</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf

	COMPLEX*16 for pzlarf. Pointer into the local memory to an array of DIMENSION (lld_v,*) containing the local pieces of the distributed vectors <i>v</i> representing the Householder transformation <i>Q</i>, <i>v</i>(iv:iv+m-1, jv) if <i>side</i> = 'L' and <i>incv</i> = 1, <i>v</i>(iv, jv:jv+m-1) if <i>side</i> = 'L' and <i>incv</i> = m_v, <i>v</i>(iv:iv+n-1, jv) if <i>side</i> = 'R' and <i>incv</i> = 1, <i>v</i>(iv, jv:jv+n-1) if <i>side</i> = 'R' and <i>incv</i> = m_v. The vector <i>v</i> is the representation of <i>Q</i>. <i>v</i> is not used if <i>tau</i> = 0.
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix sub(<i>v</i>), respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (dlen_). The array descriptor for the distributed matrix <i>V</i> .
<i>incv</i>	(global) INTEGER. The global increment for the elements of <i>v</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and m_v. <i>incv</i> must not be zero.
<i>tau</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf. Array, DIMENSION LOCc(jv) if <i>incv</i> = 1, and LOCc(iv) otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>v</i> .
<i>c</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf. Pointer into the local memory to an array of DIMENSION (lld_c, LOCc(jc+n-1)), containing the local pieces of sub(<i>c</i>).
<i>ic, jc</i>	(global) INTEGER.

The row and column indices in the global array *c* indicating the first row and the first column of the submatrix sub(*c*), respectively.

desc (global and local) INTEGER array, DIMENSION (*dlen*₁). The array descriptor for the distributed matrix *C*.

work (local).

```

REAL for pslarf
DOUBLE PRECISION for pdlarf
COMPLEX for pclarf
COMPLEX*16 for pzlarf.
Array, DIMENSION (lwork).
If incv = 1,
    if side = 'L',
        if ivcol = iccol,
            lwork ≥ nqc0
        else
            lwork ≥ mpc0 + max( 1, nqc0 )
        end if
    else if side = 'R' ,
        lwork ≥ nqc0 + max( max( 1, mpc0), numroc(numroc( n+
            icoffc,nb_v,0,0,npcol),nb_v,0,0,lcmq ) )
    end if
else if incv = m_v,
    if side = 'L',
        lwork ≥ mpc0 + max( max( 1, nqc0 ), numroc(
            numroc(m+iroffc,mb_v,0,0,nprow),mb_v,0,0, lcmp )
        )
    else if side = 'R',
        if ivrow = icrow,
            lwork ≥ mpc0
        else
            lwork ≥ nqc0 + max( 1, mpc0 )
        end if
    end if
end if,

```

where lcm is the least common multiple of $nprow$ and $npcol$ and $lcm = ilcm(nprow, npcol)$, $lcmp = lcm/nprow$, $lcmq = lcm/npcol$,
 $iroffc = mod(ic-1, mb\_c)$, $icoffc = mod(jc-1, nb\_c)$,
 $icrow = indxg2p(ic, mb\_c, myrow, rsrc\_c, nprow)$,
 $iccol = indxg2p(jc, nb\_c, mycol, csrc\_c, npcol)$,
 $mpc0 = numroc(m+iroffc, mb\_c, myrow, icrow, nprow)$,
 $nqc0 = numroc(n+icoffc, nb\_c, mycol, iccol, npcol)$,
 $ilcm$, $indxg2p$, and $numroc$ are ScaLAPACK tool functions;
 $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

c

(local).

On exit, $sub(c)$ is overwritten by the $Q * sub(C)$ if $side = 'L'$,
or $sub(c) * Q$ if $side = 'R'$.

p?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
call pslarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c,
            ic, jc, descc, work)

```

Description

This routine applies a real/complex block reflector Q or its transpose Q^T /conjugate transpose Q^H to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

<i>side</i>	(global).CHARACTER. if <i>side</i> = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left; if <i>side</i> = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Right.
<i>trans</i>	(global).CHARACTER. if <i>trans</i> = 'N': no transpose, apply Q ; for real flavors, if <i>trans</i> ='T': transpose, apply Q^T for complex flavors, if <i>trans</i> = 'C': conjugate transpose, apply Q^H ;
<i>direct</i>	(global) CHARACTER. Indicates how Q is formed from a product of elementary reflectors. if <i>direct</i> = 'F': $Q = H(1)*H(2)*\dots*H(k)$ (Forward) if <i>direct</i> = 'B': $Q = H(k)*\dots*H(2)*H(1)$ (Backward)

<i>storev</i>	(global) CHARACTER. Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': Columnwise if <i>storev</i> = 'R': Rowwise.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>k</i>	(global) INTEGER. The order of the matrix T.
<i>v</i>	(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb. Pointer into the local memory to an array of DIMENSION (<i>lld_v</i>, <i>LOCc</i>(<i>lv</i>+<i>k</i>-1)) if <i>storev</i> = 'C', (<i>lld_v</i>, <i>LOCc</i>(<i>lv</i>+<i>m</i>-1)) if <i>storev</i> = 'R' and <i>side</i> = 'L', (<i>lld_v</i>, <i>LOCc</i>(<i>lv</i>+<i>n</i>-1)) if <i>storev</i> = 'R' and <i>side</i> = 'R'. It contains the local pieces of the distributed vectors <i>v</i> representing the Householder transformation. if <i>storev</i> = 'C' and <i>side</i> = 'L', <i>lld_v</i> $\geq$ <i>max</i>(1,<i>LOCr</i>(<i>iv</i>+<i>m</i>-1)); if <i>storev</i> = 'C' and <i>side</i> = 'R', <i>lld_v</i> $\geq$ <i>max</i>(1,<i>LOCr</i>(<i>iv</i>+<i>n</i>-1)); if <i>storev</i> = 'R', <i>lld_v</i> $\geq$ <i>LOCr</i>(<i>lv</i>+<i>k</i>-1).
<i>iv, lv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.

descv (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *v*.

c (local).
 REAL for pslarfb
 DOUBLE PRECISION for pdlarfb
 COMPLEX for pclarfb
 COMPLEX*16 for pzlarfb.
 Pointer into the local memory to an array of
 DIMENSION(*lld_c*, *LOCc(jc+n-1)*), containing the local pieces of sub(*c*).

ic, jc (global) INTEGER. The row and column indices in the global array *c* indicating the first row and the first column of the submatrix sub(*c*), respectively.

descc (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *c*.

work (local).
 REAL for pslarfb
 DOUBLE PRECISION for pdlarfb
 COMPLEX for pclarfb
 COMPLEX*16 for pzlarfb.
 Workspace array, DIMENSION (*lwork*).
 If *storev* = 'C',
 if *side* = 'L',
 $lwork \geq (nqc0 + mpc0) * k$
 else if *side* = 'R',
 $lwork \geq (nqc0 + \max(npv0 + \text{numroc}(\text{numroc}(n + icoffc, nb\_v, 0, 0, npc0), nb\_v, 0, 0, lcmq), mpc0)) * k$
 end if
 else if *storev* = 'R',
 if *side* = 'L',
 $lwork \geq (mpc0 + \max(mqv0 + \text{numroc}(\text{numroc}(m + iroffc, mb\_v, 0, 0, nprow), mb\_v, 0, 0, lcmp), nqc0)) * k$
 else if *side* = 'R',
 $lwork \geq (mpc0 + nqc0) * k$

```

end if
end if,
where
lcmq = lcm / npcol with lcm = iclm( nprow, npcol ),
iroffv = mod( iv-1, mb_v ), icoffv = mod( jv-1, nb_v ),
ivrow = indxg2p( iv, mb_v, myrow, rsrc_v, nprow ),
ivcol = indxg2p( jv, nb_v, mycol, csrc_v, npcol ),
MqV0 = numroc( m+icoffv, nb_v, mycol, ivcol, npcol ),
NpV0 = numroc( n+iroffv, mb_v, myrow, ivrow, nprow ),
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nprow ),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
MpC0 = numroc( m+iroffc, mb_c, myrow, icrow, nprow ),
NpC0 = numroc( n+icoffc, mb_c, myrow, icrow, nprow ),
NqC0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npcol can be determined by
calling the subroutine blacs_gridinfo.

```

Output Parameters

<i>t</i>	(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb. Array, DIMENSION(<i>mb_v</i>, <i>mb_v</i>) if <i>storev</i> = 'R', and (<i>nb_v</i>, <i>nb_v</i>) if <i>storev</i> = 'C'. The triangular matrix <i>t</i> is the representation of the block reflector.
<i>c</i>	(local). On exit, sub(<i>c</i>) is overwritten by the $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q'$. Q' is transpose (conjugate transpose) of Q.

p?larfc

Applies the conjugate transpose of an elementary reflector to a general matrix.

Syntax

```
call pclarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Description

This routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v^H,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global) CHARACTER. if <i>side</i> = 'L': form $Q^H * \text{sub}(C)$; if <i>side</i> = 'R': form $\text{sub}(C) * Q^H$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>v</i>	(local). COMPLEX for pclarfc COMPLEX*16 for pzlarfc. Pointer into the local memory to an array of DIMENSION (<i>lld_v</i> ,*) containing the local pieces of the distributed vectors v representing the Householder transformation Q ,

$v(iv:iv+m-1, jv)$ if $side = 'L'$ and $incv = 1$,
 $v(iv, jv:jv+m-1)$ if $side = 'L'$ and $incv = m\_v$,
 $v(iv:iv+n-1, jv)$ if $side = 'R'$ and $incv = 1$,
 $v(iv, jv:jv+n-1)$ if $side = 'R'$ and $incv = m\_v$.
The vector v is the representation of Q . v is not used if $tau = 0$.

iv, jv	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $sub(v)$, respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix v .
$incv$	(global) INTEGER. The global increment for the elements of v . Only two values of $incv$ are supported in this version, namely 1 and m_v . $incv$ must not be zero.
tau	(local) COMPLEX for pclarfc COMPLEX*16 for pzlarfc. Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix v .
c	(local). COMPLEX for pclarfc COMPLEX*16 for pzlarfc. Pointer into the local memory to an array of DIMENSION ($lld\_c, LOCc(jc+n-1)$), containing the local pieces of $sub(c)$.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix $sub(c)$, respectively.
$desc$	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix c .
$work$	(local).

```

COMPLEX for polarfc
COMPLEX*16 for pzlarfc.
Workspace array, DIMENSION (lwork).
If incv = 1,
  if side = 'L' ,
    if ivcol = iccol,
      lwork ≥ nqc0
    else
      lwork ≥ mpc0 + max( 1, nqc0 )
    end if
  else if side = 'R' ,
    lwork ≥ nqc0 + max( max( 1, mpc0 ), numroc( numroc(
      n+icoffc,nb_v,0,0,npcol ), nb_v,0,0,lcmq ) )
    end if
  else if incv = m_v,
    if side = 'L' ,
      lwork ≥ mpc0 + max( max( 1, nqc0 ), numroc( numroc(
        m+iroffc,mb_v,0,0,nprow ),mb_v,0,0,lcmp ) )
    else if side = 'R' ,
      if ivrow = icrow,
        lwork ≥ mpc0
      else
        lwork ≥ nqc0 + max( 1, mpc0 )
      end if
    end if
  end if,
where lcm is the least common multiple of nprow and npcol
and lcm = ilcm(nprow, npcol),
lcmp = lcm/nprow, lcmq = lcm/npcol,
iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1,
nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),

mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npcol),

```

`ilcm`, `indxg2p`, and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nrow`, and `ncol` can be determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

`c` (local).
On exit, `sub(c)` is overwritten by the $Q^H \cdot \text{sub}(C)$ if `side = 'L'`, or `sub(C) * Q^H` if `side = 'R'`.

p?larfg

Generates an elementary reflector (Householder matrix).

Syntax

```
call pslarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pdlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pclarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pzlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
```

Description

This routine generates a real/complex elementary reflector H of order n , such that

$$H^* \text{sub}(X) = H^* (x(iax, jax)) = (\alpha), \quad H'^* H = I,$$

$$\begin{pmatrix} x \\ 0 \end{pmatrix}$$

where α is a scalar (a real scalar - for complex flavors), and `sub(X)` is an $(n-1)$ -element real/complex distributed vector $X(ix:ix+n-2, jx)$ if `incx = 1` and $X(ix, jx:jx+n-2)$ if `incx = descx(m_)`. H is represented in the form

$$H = I - \tau \begin{pmatrix} 1 \\ v \end{pmatrix} \begin{pmatrix} 1 & v' \end{pmatrix},$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that H is not Hermitian.

If the elements of `sub(x)` are all zero (and $X(iax, jax)$ is real for complex flavors), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise $1 \leq \text{real}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$.

Input Parameters

n (global) INTEGER.
The global order of the elementary reflector. $n \geq 0$.

iax, jax (global) INTEGER.
The global row and column indices in *x* of $X(iax, jax)$.

x (local).
Real for pslarfg
DOUBLE PRECISION for pdlarfg
COMPLEX for pclarfg
COMPLEX*16 for pzlarfg.
Pointer into the local memory to an array of DIMENSION (*lld_x*, *). This array contains the local pieces of the distributed vector sub(*x*). Before entry, the incremented array sub(*x*) must contain vector *x*.

ix, jx (global) INTEGER.
The row and column indices in the global array *x* indicating the first row and the first column of sub(*x*), respectively.

descx (global and local) INTEGER.
Array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix *x*.

incx (global) INTEGER.
The global increment for the elements of *x*. Only two values of *incx* are supported in this version, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

alpha (local)
REAL for pslafg
DOUBLE PRECISION for pdlafg
COMPLEX for pclafg
COMPLEX*16 for pzlafg.
On exit, *alpha* is computed in the process scope having the vector sub(*x*).

x (local).
On exit, it is overwritten with the vector *v*.

tau (local).
Real for `pslarfg`
DOUBLE PRECISION for `pdlarfg`
COMPLEX for `pclarfg`
COMPLEX*16 for `pzlarfg`.
Array, DIMENSION *LOCc(jx)* if *incx* = 1, and *LOCr(ix)* otherwise. This array contains the Householder scalars related to the Householder vectors.
tau is tied to the distributed matrix *X*.

p?larft

Forms the triangular vector *T* of a block reflector

$$H = I - V * T * V^H.$$

Syntax

```
call pslarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Description

This routine forms the triangular factor *T* of a real/complex block reflector *H* of order *n*, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F', $H = H(1) * H(2) \dots * H(k)$, and *T* is upper triangular;

If *direct* = 'B', $H = H(k) * \dots * H(2) * H(1)$, and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th column of the distributed matrix *V*, and

$$H = I - V * T * V'$$

If *storev* = 'R', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th row of the distributed matrix *V*, and

$$H = I - V' * T * V.$$

Input Parameters

<i>direct</i>	(global) CHARACTER*1. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) if <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward).
<i>storev</i>	(global) CHARACTER*1. Specifies how the vectors that define the elementary reflectors are stored (See <i>Application Notes</i> below): if <i>storev</i> = 'C': columnwise; if <i>storev</i> = 'R': rowwise.
<i>n</i>	(global) INTEGER. The order of the block reflector H. $n \geq 0$.
<i>k</i>	(global) INTEGER. The order of the triangular factor T, is equal to the number of elementary reflectors. $1 \leq k \leq mb\_v$ ($= nb\_v$).
<i>v</i>	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Pointer into the local memory to an array of local DIMENSION ($LOCr(iv+n-1), LOCc(jv+k-1)$) if <i>storev</i> = 'C', and ($LOCr(iv+k-1), LOCc(jv+n-1)$) if <i>storev</i> = 'R'. The distributed matrix v contains the Householder vectors. (See <i>Application Notes</i> below).
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $sub(v)$, respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix v.
<i>tau</i>	(local) REAL for pslarft DOUBLE PRECISION for pdlarft

COMPLEX for pclarft
 COMPLEX*16 for pzlarft.
Array, DIMENSIONLOCr($iv+k-1$) if $incv = m\_v$, and
 LOCc($jv+k-1$) otherwise. This array contains the
 Householder scalars related to the Householder vectors.
 tau is tied to the distributed matrix v .

work (local).
 REAL for psclarft
 DOUBLE PRECISION for pdclarft
 COMPLEX for pclarft
 COMPLEX*16 for pzlarft.
Workspace array, DIMENSION ($k*(k-1)/2$).

Output Parameters

v REAL for psclarft
 DOUBLE PRECISION for pdclarft
 COMPLEX for pclarft
 COMPLEX*16 for pzlarft.

t (local)
 REAL for psclarft
 DOUBLE PRECISION for pdclarft
 COMPLEX for pclarft
 COMPLEX*16 for pzlarft.
Array, DIMENSION (nb_v, nb_v) if $storev = 'C'$, and
 (mb_v, mb_v) otherwise. It contains the k -by- k triangular
 factor of the block reflector associated with v . If $direct =$
 'F', t is upper triangular;
 if $direct = 'B'$, t is lower triangular.

Application Notes

The shape of the matrix v and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct = 'F' and *storev* = 'C' :

$$V(i_v : i_v + n - 1, \\ j_v : j_v + k - 1) = \begin{bmatrix} 1 & & & \\ v_1 & 1 & & \\ v_1 & v_2 & 1 & \\ v_1 & v_2 & v_3 & \\ v_1 & v_2 & v_3 & \end{bmatrix}$$

direct = 'F' and *storev* = 'R' :

$$V(i_v : i_v + k - 1, \\ j_v : j_v + n - 1) = \begin{bmatrix} 1 & v_1 & v_1 & v_1 & v_1 \\ & 1 & v_2 & v_2 & v_2 \\ & & 1 & v_3 & v_3 \end{bmatrix}$$

direct = 'B' and *storev* = 'C' :

$$V(i_v : i_v + n - 1, \\ j_v : j_v + k - 1) = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \\ 1 & v_2 & v_3 \\ & 1 & v_3 \\ & & 1 \end{bmatrix}$$

direct = 'B' and *storev* = 'R' :

$$V(i_v : i_v + k - 1, \\ j_v : j_v + n - 1) = \begin{bmatrix} v_1 & v_1 & 1 \\ v_2 & v_2 & v_2 & 1 \\ v_3 & v_3 & v_3 & v_3 & 1 \end{bmatrix}$$

p?larz

Applies an elementary reflector as returned by p?tzzrf to a general matrix.

Syntax

```
call pslarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

```
call pdlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

```
call pclarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

```
call pzlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

Description

This routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by [p?tzzrf](#).

Input Parameters

<i>side</i>	(global) CHARACTER. if <i>side</i> = 'L': form $Q * \text{sub}(C)$, if <i>side</i> = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$ (for real flavors).
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>l</i>	(global). INTEGER. The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$.
<i>v</i>	(local). REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz. Pointer into the local memory to an array of DIMENSION (<i>lld_v</i> ,*) containing the local pieces of the distributed vectors v representing the Householder transformation Q ,

	$v(iv:iv+l-1, jv)$ if $side = 'L'$ and $incv = 1$, $v(iv, jv:jv+l-1)$ if $side = 'L'$ and $incv = m\_v$, $v(iv:iv+l-1, jv)$ if $side = 'R'$ and $incv = 1$, $v(iv, jv:jv+l-1)$ if $side = 'R'$ and $incv = m\_v$. The vector v in the representation of Q. v is not used if $tau = 0$.
iv, jv	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $sub(v)$, respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix v .
$incv$	(global) INTEGER. The global increment for the elements of v . Only two values of $incv$ are supported in this version, namely 1 and m_v . $incv$ must not be zero.
tau	(local) REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz. Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix v .
c	(local). REAL for pslarz DOUBLE PRECISION for pdlarz COMPLEX for pclarz COMPLEX*16 for pzlarz. Pointer into the local memory to an array of DIMENSION ($lld\_c, LOCc(jc+n-1)$), containing the local pieces of $sub(c)$.
ic, jc	(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix $sub(c)$, respectively.

desc (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *c*.

work (local).
 REAL for pslarz
 DOUBLE PRECISION for pdlarz
 COMPLEX for pclarz
 COMPLEX*16 for pzlarz.

`myrow, mycol, nprow, and npcol` can be determined by
calling the subroutine `blacs_gridinfo`.

Output Parameters

`c` (local).
On exit, `sub(c)` is overwritten by the $Q \cdot \text{sub}(C)$ if `side = 'L'`, or `sub(C) * Q` if `side = 'R'`.

p?larzb

Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzzrf to a general matrix.

Syntax

`call pslarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)`

`call pdlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)`

`call pclarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)`

`call pzlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)`

Description

This routine applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m -by- n matrix `sub(C) = C(ic:ic+m-1, jc:jc+n-1)` from the left or the right.

Q is a product of k elementary reflectors as returned by `p?tzzrf`.

Currently, only `storev = 'R'` and `direct = 'B'` are supported.

Input Parameters

<i>side</i>	(global) CHARACTER. if <i>side</i> = 'L': apply Q or Q^T (Q^H for complex flavors) from the Left; if <i>side</i> = 'R': apply Q or Q^T (Q^H for complex flavors) from the Right.
<i>trans</i>	(global) CHARACTER. if <i>trans</i> = 'N': No transpose, apply Q; If <i>trans</i>='T': Transpose, apply Q^T (real flavors); If <i>trans</i>='C': Conjugate transpose, apply Q^H (complex flavors).
<i>direct</i>	(global) CHARACTER. Indicates how H is formed from a product of elementary reflectors. if <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ - forward (not supported) ; if <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ - backward.
<i>storev</i>	(global) CHARACTER. Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': columnwise (not supported). if <i>storev</i> = 'R': rowwise.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>C</i>). ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(<i>C</i>). ($n \geq 0$).
<i>k</i>	(global) INTEGER. The order of the matrix T. (= the number of elementary reflectors whose product defines the block reflector).
<i>l</i>	(global) INTEGER. The columns of the distributed submatrix sub(<i>A</i>) containing the meaningful part of the Householder reflectors.

	If $side = 'L', m \geq l \geq 0,$ if $side = 'R', n \geq l \geq 0.$
v	(local). REAL for pslarzb DOUBLE PRECISION for pdlarzb COMPLEX for pclarzb COMPLEX*16 for pzlarzb. Pointer into the local memory to an array of DIMENSION($lld\_v, LOCc(jv+m-1)$) if $side = 'L',$ ($lld\_v, LOCc(jv+m-1)$) if $side = 'R'.$ It contains the local pieces of the distributed vectors v representing the Householder transformation as returned by p?tzzrf. $lld\_v \geq LOCr(iv+k-1).$
iv, jv	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix sub(v), respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix v.
t	(local) REAL for pslarzb DOUBLE PRECISION for pdlarzb COMPLEX for pclarzb COMPLEX*16 for pzlarzb. Array, DIMENSION mb_v by $mb\_v.$ The lower triangular matrix T in the representation of the block reflector.
c	(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb. Pointer into the local memory to an array of DIMENSION($lld\_c, LOCc(jc+n-1)$). On entry, the m-by-n distributed matrix sub(c).

ic, jc (global) INTEGER.
The row and column indices in the global array *c* indicating the first row and the first column of the submatrix sub(*c*), respectively.

descc (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *c*.

work (local).
REAL for pslarzb
DOUBLE PRECISION for pdlarzb
COMPLEX for pclarzb
COMPLEX*16 for pzlarzb.
Array, DIMENSION (*lwork*).
If storev = 'C' ,
 if side = 'L' ,
 $lwork \geq (nqc0 + mpc0) * k$
 else if side = 'R' ,
 $lwork \geq (nqc0 + \max(npv0 + \text{numroc}(\text{numroc}(n+icoffc, nb\_v, 0, 0, npc0),$
 $nb\_v, 0, 0, lcmq), mpc0)) * k$
 end if
else if storev = 'R' ,
 if side = 'L' ,
 $lwork \geq (mpc0 + \max(mqv0 + \text{numroc}(\text{numroc}(m+iroffc, mb\_v, 0, 0, nprow),$
 $mb\_v, 0, 0, lcmp), nqc0)) * k$
 else if side = 'R' ,
 $lwork \geq (mpc0 + nqc0) * k$
 end if
end if.

Here $lcmq = lcm / npc0$ with $lcm = iclm(nprow, npc0)$,

```

iroffv = mod(iv-1, mb_v), icoffv = mod( jv-1,
nb_v),
ivrow = indxg2p(iv, mb_v, myrow, rsrc_v, nprow),
ivcol = indxg2p(jv, nb_v, mycol, csrc_v, npcol),
mqv0 = numroc(m+icoffv, nb_v, mycol, ivcol,
npcol),
npv0 = numroc(n+iroffv, mb_v, myrow, ivrow,
nprow),
iroffc = mod(ic-1, mb_c ), icoffc= mod( jc-1,
nb_c),
icrow= indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol= indxg2p(jc, nb_c, mycol, csrc_c, npcol),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
npc0 = numroc(n+icoffc, mb_c, myrow, icrow,
nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npcol can be determined by
calling the subroutine blacs_gridinfo.

```

Output Parameters

c

(local).

On exit, $\text{sub}(c)$ is overwritten by the $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q'$, where Q' is the transpose (conjugate transpose) of Q .

p?larzc

Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzzrf to a general matrix.

Syntax

```
call pclarzc(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)

call pzlarzc(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc,
work)
```

Description

This routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v^H,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by p?tzzrf.

Input Parameters

<i>side</i>	(global) CHARACTER. if <i>side</i> = 'L': form $Q^H * \text{sub}(C)$; if <i>side</i> = 'R': form $\text{sub}(C) * Q^H$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>l</i>	(global) INTEGER.

	The columns of the distributed submatrix $\text{sub}(\underline{A})$ containing the meaningful part of the Householder reflectors. If $\text{side} = \text{'L'}, m \geq l \geq 0$, if $\text{side} = \text{'R'}, n \geq l \geq 0$.
v	(local). COMPLEX for pclarzc COMPLEX*16 for pzlarzc. Pointer into the local memory to an array of DIMENSION ($lld_v, *$) containing the local pieces of the distributed vectors v representing the Householder transformation Q, $v(iv:iv+l-1, jv)$ if $\text{side} = \text{'L'}$ and $incv = 1$, $v(iv, jv:jv+l-1)$ if $\text{side} = \text{'L'}$ and $incv = m_v$, $v(iv:iv+l-1, jv)$ if $\text{side} = \text{'R'}$ and $incv = 1$, $v(iv, jv:jv+l-1)$ if $\text{side} = \text{'R'}$ and $incv = m_v$. The vector v in the representation of Q. v is not used if $\tau = 0$.
iv, jv	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
$descv$	(global and local) INTEGER array, DIMENSION ($dlen\_v$). The array descriptor for the distributed matrix v.
$incv$	(global). INTEGER. The global increment for the elements of v. Only two values of $incv$ are supported in this version, namely 1 and m_v. $incv$ must not be zero.
τ	(local) COMPLEX for pclarzc COMPLEX*16 for pzlarzc. Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. τ is tied to the distributed matrix v.
c	(local). COMPLEX for pclarzc COMPLEX*16 for pzlarzc.

	Pointer into the local memory to an array of <code>DIMENSION(<i>lld_c</i>, <i>LOCc(jc+n-1)</i>)</code>, containing the local pieces of <code>sub(c)</code>.
<i>ic, jc</i>	(global) <code>INTEGER</code>. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix <code>sub(c)</code>, respectively.
<i>desc</i>	(global and local) <code>INTEGER</code> array, <code>DIMENSION(<i>dlen_</i>)</code>. The array descriptor for the distributed matrix <i>c</i>.

work

```
(local).
If incv = 1,
    if side = 'L' ,
        if ivcol = iccol,
            lwork ≥ nqc0
        else
            lwork ≥ mpc0 + max(1, nqc0)
        end if
    else if side = 'R' ,
        lwork ≥ nqc0 + max(max(1, mpc0),
numroc(numroc(n+icoffc, nb_v, 0, 0, npcol),
            nb_v, 0, 0, lcmq))
        end if
    else if incv = m_v,
        if side = 'L' ,
            lwork ≥ mpc0 + max(max(1, nqc0),
numroc(numroc(m+iroffc, mb_v, 0, 0, nprow),
            mb_v, 0, 0, lcmp))
        else if side = 'R',
            if ivrow = icrow,
                lwork ≥ mpc0
            else
                lwork ≥ nqc0 + max(1, mpc0)
            end if
        end if
    end if
end if
```

Here *lcm* is the least common multiple of *nprow* and *npcol*;

```
lcm = ilcm(nprow, npc0l), lcmp = lcm/nprow, lcmq =
lcm/npcol,
iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1,
nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc0l),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npc0l),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;
myrow, mycol, nprow, and npc0l can be determined by
calling the subroutine blacs_gridinfo.
```

Output Parameters

c (local).
On exit, *sub(c)* is overwritten by the $Q^H * \text{sub}(C)$ if *side* = 'L', or *sub(C) * Q^H* if *side* = 'R'.

p?larzt

Forms the triangular factor *T* of a block reflector
 $H = I - V * T * V^H$ as returned by p?tzzrf.

Syntax

```
call pslarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzlarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Description

This routine forms the triangular factor *T* of a real/complex block reflector *H* of order greater than *n*, which is defined as a product of *k* elementary reflectors as returned by p?tzzrf.

If *direct* = 'F', $H = H(1) * H(2) * \dots * H(k)$, and *T* is upper triangular;

If *direct* = 'B', $H = H(k) * \dots * H(2) * H(1)$, and *T* is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$, is stored in the i -th column of the array v , and

$$H = I - v * t * v'.$$

If $storev = 'R'$, the vector, which defines the elementary reflector $H(i)$, is stored in the i -th row of the array v , and

$$H = I - v' * t * v$$

Currently, only $storev = 'R'$ and $direct = 'B'$ are supported.

Input Parameters

<i>direct</i>	(global) CHARACTER. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $direct = 'F'$: $H = H(1) * H(2) * \dots * H(k)$ (Forward, not supported) if $direct = 'B'$: $H = H(k) * \dots * H(2) * H(1)$ (Backward).
<i>storev</i>	(global) CHARACTER. Specifies how the vectors which defines the elementary reflectors are stored: if $storev = 'C'$: columnwise (not supported); if $storev = 'R'$: rowwise.
<i>n</i>	(global). INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global). INTEGER. The order of the triangular factor T (= the number of elementary reflectors). $1 \leq k \leq mb\_v (= nb\_v)$.
<i>v</i>	REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Pointer into the local memory to an array of local $DIMENSION(LOCr(iv+k-1), LOCc(jv+n-1))$. The distributed matrix v contains the Householder vectors. See <i>Application Notes</i> below.

<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix <i>sub(v)</i> , respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>v</i> .
<i>tau</i>	(local) REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Array, DIMENSION <i>LOCr(iv+k-1)</i> if <i>incv = m_v</i> , and <i>LOCc(jv+k-1)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>v</i> .
<i>work</i>	(local). REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Workspace array, DIMENSION (<i>k*(k-1)/2</i>).

Output Parameters

<i>v</i>	REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt.
<i>t</i>	(local) REAL for pslarzt DOUBLE PRECISION for pdlarzt COMPLEX for pclarzt COMPLEX*16 for pzlarzt. Array, DIMENSION (<i>mb_v, mb_v</i>). It contains the <i>k</i> -by- <i>k</i> triangular factor of the block reflector associated with <i>v</i> . <i>t</i> is lower triangular.

Application Notes

The shape of the matrix v and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct='F' and storev='C'

$$v = \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

$$v = \begin{bmatrix} . & . & . \\ . & . & . \\ 1 & . & . \\ . & 1 & . \\ . & . & 1 \end{bmatrix}$$

direct='F' and storev='R'

$$\begin{bmatrix} \overbrace{v1 \ v1 \ v1 \ v1 \ v1}^v & . & . & . & 1 \\ v2 \ v2 \ v2 \ v2 \ v2 & . & . & . & 1 \\ v3 \ v3 \ v3 \ v3 \ v3 & . & . & . & 1 \end{bmatrix}$$

direct='B' and storev='C'

$$v = \begin{bmatrix} 1 \\ . & 1 \\ . & . & 1 \\ . & . & . \\ . & . & . \end{bmatrix}$$

$$\begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

direct='B' and storev='R':

$$\begin{bmatrix} 1 & . & . & . & \overbrace{.v1 \ v1 \ v1 \ v1 \ v1}^Y \\ . & 1 & . & . & .v2 \ v2 \ v2 \ v2 \ v2 \\ . & . & 1 & . & .v3 \ v3 \ v3 \ v3 \ v3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} .

Syntax

```
call pslascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pdlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pclascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pzlascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
```

Description

This routine multiplies the m -by- n real/complex distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto*A(i, j)/cfrom$ does not over/underflow. *type* specifies that $\text{sub}(A)$ may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

<i>type</i>	(global) CHARACTER. <i>type</i> indicates the storage type of the input distributed matrix. if <i>type</i> = 'G': $\text{sub}(A)$ is a full matrix, if <i>type</i> = 'L': $\text{sub}(A)$ is a lower triangular matrix, if <i>type</i> = 'U': $\text{sub}(A)$ is an upper triangular matrix, if <i>type</i> = 'H': $\text{sub}(A)$ is an upper Hessenberg matrix.
<i>cfrom, cto</i>	(global)

	REAL for pslascl/pclascl DOUBLE PRECISION for pdlascl/pzlascl. The distributed matrix $\text{sub}(A)$ is multiplied by $cto/cfrom$. $A(i,j)$ is computed without over/underflow if the final result $cto * A(i,j) / cfrom$ can be represented without over/underflow. $cfrom$ must be nonzero.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local input/local output) REAL for pslascl DOUBLE PRECISION for pdlascl COMPLEX for pcascl COMPLEX*16 for pzlascl. Pointer into the local memory to an array of DIMENSION(<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The column and row indices in the global array <i>A</i> indicating the first row and column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER . Array of DIMENSION (<i>dlen_</i>).The array descriptor for the distributed matrix <i>A</i>.

Output Parameters

<i>a</i>	(local). On exit, this array contains the local pieces of the distributed matrix multiplied by $cto/cfrom$.
<i>info</i>	(local) INTEGER.

if *info* = 0: the execution is successful.
 if *info* < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$,
 if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

p?laset

Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.

Syntax

```
call pslaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pdlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pclaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pzlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
```

Description

This routine initializes an *m*-by-*n* distributed matrix sub(*A*) denoting *A*(*ia:ia+m-1*, *ja:ja+n-1*) to *beta* on the diagonal and *alpha* on the offdiagonals.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the part of the distributed matrix sub(<i>A</i>) to be set: if <i>uplo</i> = 'U': upper triangular part; the strictly lower triangular part of sub(<i>A</i>) is not changed; if <i>uplo</i> = 'L': lower triangular part; the strictly upper triangular part of sub(<i>A</i>) is not changed. Otherwise: all of the matrix sub(<i>A</i>) is set.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>A</i>). ($m \geq 0$).
<i>n</i>	(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$.
 $(n \geq 0)$.

alpha (global).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzlaset.
 The constant to which the offdiagonal elements are to be set.

beta (global).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzlaset.
 The constant to which the diagonal elements are to be set.

Output Parameters

a (local).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzlaset.
 Pointer into the local memory to an array of
 DIMENSION(*lld_a*, *LOCc(ja+n-1)*).
 This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading m -by- n submatrix $\text{sub}(A)$ is set as follows:

if *uplo* = 'U', $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq j-1,$
 $1 \leq j \leq n,$

if *uplo* = 'L', $A(ia+i-1, ja+j-1) = \alpha, j+1 \leq i \leq m,$
 $1 \leq j \leq n,$

otherwise, $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq m, 1 \leq j \leq n,$
 $ia+i.ne.ja+j,$ and, for all *uplo*, $A(ia+i-1, ja+i-1) =$
 $\beta, 1 \leq i \leq \min(m, n).$

<i>ia, ja</i>	(global) INTEGER. The column and row indices in the global array <i>A</i> indicating the first row and column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER . Array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```
call pslasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pdlasmsub(a, desca, i, l, k, smlnum, buf, lwork)
```

Description

This routine looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This routine does a global maximum and must be called by all processes.

Input Parameters

<i>a</i>	(global) REAL for pslasmsub DOUBLE PRECISION for pdlasmsub Array, DIMENSION (<i>desca(lld_)</i> , *). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of <i>A</i> . Unchanged on exit.
<i>l</i>	(global) INTEGER.

The global location of the top of the unreduced submatrix of A .
 Unchanged on exit.

smlnum (global)
 REAL for pslasmsub
 DOUBLE PRECISION for pdlasmsub
 On entry, a “small number” for the given matrix. Unchanged on exit.

lwork (global) INTEGER.
 On exit, *lwork* is the size of the work buffer.
 This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcot))$. Here *lcm* is least common multiple, and $nprow \times npcot$ is the logical grid size.

Output Parameters

k (global) INTEGER.
 On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $1 \leq m \leq i-1$.

buf (local).
 REAL for pslasmsub
 DOUBLE PRECISION for pdlasmsub
 Array of size *lwork*.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call pslasq(n, x, ix, jx, descx, incx, scale, sumsq)
call pdlasq(n, x, ix, jx, descx, incx, scale, sumsq)
call pclasq(n, x, ix, jx, descx, incx, scale, sumsq)
call pzlasq(n, x, ix, jx, descx, incx, scale, sumsq)
```

Description

This routine returns the values *scl* and *sumsq* such that

$$scl^2 * sumsq = x(1)^2 + \dots + x(n)^2 + scale^2 * sumsq,$$

where $x(i) = \text{sub}(X) = X(ix + (jx-1)*descx(m_) + (i - 1)*incx)$ for
plassq/pdllassq ,

and $x(i) = \text{sub}(X) = \text{abs}(X(ix + (jx-1)*descx(m_) + (i - 1)*incx))$ for
pclassq/pzlassq.

For real routines plassq/pdllassq the value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(x(i))).$$

For complex routines pclassq/pzlassq the value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value *scale* is assumed to be non-negative and *scl* returns the value

$$scl = \max_i \left(scale, \text{abs}(\text{real}(x(i))), \text{abs}(\text{aimag}(x(i))) \right)$$

For all routines p?lassq values *scale* and *sumsq* must be supplied in *scale* and *sumsq* respectively, and *scale* and *sumsq* are overwritten by *scl* and *ssq* respectively.

All routines p?lassq make only one pass through the vector $\text{sub}(x)$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of the distributed vector $\text{sub}(x)$.
<i>x</i>	REAL for plassq DOUBLE PRECISION for pdllassq COMPLEX for pclassq COMPLEX*16 for pzlassq. The vector for which a scaled sum of squares is computed: $x(ix + (jx-1)*m_x + (i - 1)*incx)$, $1 \leq i \leq n$.
<i>ix</i>	(global) INTEGER.

	The row index in the global array x indicating the first row of $\text{sub}(x)$.
jx	(global) INTEGER. The column index in the global array x indicating the first column of $\text{sub}(x)$.
$descx$	(global and local) INTEGER array of DIMENSION ($dlen\_$). The array descriptor for the distributed matrix x .
$incx$	(global) INTEGER. The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . The argument $incx$ must not equal zero.
$scale$	(local). REAL for psllassq/pclassq DOUBLE PRECISION for pdlassq/pzlassq. On entry, the value $scale$ in the equation above.
$sumsq$	(local) REAL for psllassq/pclassq DOUBLE PRECISION for pdlassq/pzlassq. On entry, the value $sumsq$ in the equation above.

Output Parameters

$scale$	(local). On exit, $scale$ is overwritten with scl , the scaling factor for the sum of squares.
$sumsq$	(local). On exit, $sumsq$ is overwritten with the value $smsq$, the basic sum of squares from which scl has been factored out.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call pslaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pdlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pclaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pzlaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
```

Description

This routine performs a series of row or column interchanges on the distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$. One interchange is initiated for each of rows or columns $k1$ through $k2$ of $\text{sub}(A)$. This routine assumes that the pivoting information has already been broadcast along the process row or column. Also note that this routine will only work for $k1-k2$ being in the same *mb* (or *nb*) block. If you want to pivot a full matrix, use [p?lapiv](#).

Input Parameters

<i>direc</i>	(global) CHARACTER. Specifies in which order the permutation is applied: = 'F' - forward, = 'B' - backward.
<i>rowcol</i>	(global) CHARACTER. Specifies if the rows or columns are permuted: = 'R' - rows, = 'C' - columns.
<i>n</i>	(global) INTEGER. If <i>rowcol</i> ='R', the length of the rows of the distributed matrix $A(*, ja:ja+n-1)$ to be permuted; If <i>rowcol</i> ='C', the length of the columns of the distributed matrix $A(ia:ia+n-1, *)$ to be permuted;
<i>a</i>	(local) REAL for pslaswp DOUBLE PRECISION for pdlaswp COMPLEX for pclaswp

	COMPLEX*16 for pzlaswp. Pointer into the local memory to an array of DIMENSION (lld_a, *). On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (dlen_). The array descriptor for the distributed matrix <i>A</i> .
<i>k1</i>	(global) INTEGER. The first element of <i>ipiv</i> for which a row or column interchange will be done.
<i>k2</i>	(global) INTEGER. The last element of <i>ipiv</i> for which a row or column interchange will be done.
<i>ipiv</i>	(local) INTEGER. Array, DIMENSION LOCr(m_a)+mb_a for row pivoting and LOCr(n_a)+nb_a for column pivoting. This array is tied to the matrix <i>A</i> , <i>ipiv</i> (<i>k</i>)=1 implies rows (or columns) <i>k</i> and 1 are to be interchanged.

Output Parameters

<i>A</i>	(local) REAL for pslaswp DOUBLE PRECISION for pdlaswp COMPLEX for pclaswp COMPLEX*16 for pzlaswp. On exit, the permuted distributed matrix.

p?latra

Computes the trace of a general square distributed matrix.

Syntax

```
val = pslatra(n, a, ia, ja, desca)
val = pdlatra(n, a, ia, ja, desca)
val = pclatra(n, a, ia, ja, desca)
val = pzlatra(n, a, ia, ja, desca)
```

Description

This function computes the trace of an n -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$. The result is left on every process of the grid.

Input Parameters

n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
a	(local). Real for pslatra DOUBLE PRECISION for pdlatra COMPLEX for pclatra COMPLEX*16 for pzlatra. Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCc(ja+n-1))</code> containing the local pieces of the distributed matrix, the trace of which is to be computed.
ia, ja	(global) INTEGER. The row and column indices respectively in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
$desca$	(global and local) INTEGER array of <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix A .

Output Parameters

`val` The value returned by the fuction.

p?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call pslatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pdlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pclatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pzlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
```

Description

This routine reduces nb rows and columns of a real symmetric or complex Hermitian matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation $Q'^* \text{sub}(A) Q$, and returns the matrices V and W , which are needed to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $uplo = U$, p?latrd reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if $uplo = L$, p?latrd reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by p?sytrd/p?hetrd.

Input Parameters

`uplo` (global) CHARACTER.
Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored:
= 'U': Upper triangular
= 'L': Lower triangular.

`n` (global) INTEGER.

	The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>nb</i>	(global) INTEGER. The number of rows and columns to be reduced.
<i>a</i>	REAL for <code>pslatrd</code> DOUBLE PRECISION for <code>pdlatrd</code> COMPLEX for <code>pclatrd</code> COMPLEX*16 for <code>pzlatrd</code> . Pointer into the local memory to an array of <code>DIMENSION (lld_a, LOcc(ja+n-1))</code> . On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = U, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = L, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of $\text{sub}(A)$.
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of $\text{sub}(A)$.
<i>desca</i>	(global and local) INTEGER array of <code>DIMENSION (dlen_)</code> . The array descriptor for the distributed matrix <i>A</i> .
<i>iw</i>	(global) INTEGER. The row index in the global array <i>W</i> indicating the first row of $\text{sub}(W)$.
<i>jw</i>	(global) INTEGER. The column index in the global array <i>W</i> indicating the first column of $\text{sub}(W)$.
<i>descw</i>	(global and local) INTEGER array of <code>DIMENSION (dlen_)</code> . The array descriptor for the distributed matrix <i>W</i> .
<i>work</i>	(local) REAL for <code>pslatrd</code>

DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Workspace array of DIMENSION (nb_a).

Output Parameters

a (local)
 On exit, if $uplo = 'U'$, the last nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $sub(A)$; the elements above the diagonal with the array τ represent the orthogonal/unitary matrix Q as a product of elementary reflectors;
 if $uplo = 'L'$, the first nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $sub(A)$; the elements below the diagonal with the array τ represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

d (local)
 REAL for pslatrd/pclatrd
 DOUBLE PRECISION for pdlatrd/pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$.
 The diagonal elements of the tridiagonal matrix T : $d(i) = a(i, i)$. d is tied to the distributed matrix A .

e (local)
 REAL for pslatrd/pclatrd
 DOUBLE PRECISION for pdlatrd/pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$ if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise.
 The off-diagonal elements of the tridiagonal matrix T :
 $e(i) = a(i, i + 1)$ if $uplo = 'U'$,
 $e(i) = a(i + 1, i)$ if $uplo = 'L'$.
 e is tied to the distributed matrix A .

tau (local)
 REAL for pslatrd
 DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd

COMPLEX*16 for pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$. This array contains the scalar factors τ of the elementary reflectors. τ is tied to the distributed matrix A .

w (local)
 REAL for pslatrd
 DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Pointer into the local memory to an array of DIMENSION (lld_w, nb_w) . This array contains the local pieces of the n -by- nb_w matrix w required to update the unreduced part of $sub(A)$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-1, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1: ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The elements of the vectors v together form the n -by- nb matrix v which is needed, with w , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$ update of the form:

$$sub(A) := sub(A) - v w' - w v'.$$

The contents of a on exit are illustrated by the following examples with

$$n = 5 \text{ and } nb = 2:$$

$$\begin{array}{cc}
 \text{if } \text{uplo} = 'U': & \text{if } \text{uplo} = 'L': \\
 \begin{bmatrix} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{bmatrix} & \begin{bmatrix} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{bmatrix}
 \end{array}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

p?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```
call pslatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

```
call pdlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

```
call pclatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

```
call pzlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx,
scale, cnorm, work)
```

Description

This routine solves a triangular system of equations $Ax = sb$, $A^T x = sb$ or $A^H x = sb$, where s is a scale factor set to prevent overflow. The description of the routine will be extended in the future releases.

Input Parameters

`uplo` CHARACTER*1.

	Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	CHARACTER*1. Specifies the operation applied to Ax . = 'N': Solve $Ax = s*b$ (no transpose) = 'T': Solve $A^T x = s*b$ (transpose) = 'C': Solve $A^H x = s*b$ (conjugate transpose), where s - is a scale factor
<i>diag</i>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular
<i>normin</i>	CHARACTER*1. Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	INTEGER. The order of the matrix A . $n \geq 0$
<i>a</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs Array, DIMENSION (<i>lda</i> , <i>n</i>). Contains the triangular matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced. If <i>diag</i> = 'U', the diagonal elements of <i>a</i> are also not referenced and are assumed to be 1.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>x</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs Array, DIMENSION (<i>n</i>). On entry, the right hand side <i>b</i> of the triangular system.
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of sub(<i>x</i>).
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of sub(<i>x</i>).
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>x</i> .
<i>cnorm</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs. Array, DIMENSION (<i>n</i>). If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> (<i>j</i>) contains the norm of the off-diagonal part of the <i>j</i> -th column of <i>A</i> . If <i>trans</i> = 'N', <i>cnorm</i> (<i>j</i>) must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i> (<i>j</i>) must be greater than or equal to the 1-norm.
<i>work</i>	(local). REAL for pslatrs DOUBLE PRECISION for pdlatrs COMPLEX for pclatrs COMPLEX*16 for pzlatrs. Temporary workspace.

Output Parameters

<i>x</i>	On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .
<i>scale</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs. Array, DIMENSION (<i>lda</i> , <i>n</i>). The scaling factor <i>s</i> for the triangular system as described above.

If $scale = 0$, the matrix A is singular or badly scaled, and the vector x is an exact or approximate solution to $Ax = 0$.

cnorm

If $normin = 'N'$, *cnorm* is an output argument and *cnorm*(j) returns the 1-norm of the off-diagonal part of the j -th column of A .

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

```
call pslatz(m, n, l, a, ia, ja, desca, tau, work)
call pdlatrz(m, n, l, a, ia, ja, desca, tau, work)
call pclatz(m, n, l, a, ia, ja, desca, tau, work)
call pzlatrz(m, n, l, a, ia, ja, desca, tau, work)
```

Description

This routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $sub(A) = [A(ia:ia+m-1, ja:ja+m-1) \ A(ia:ia+m-1, ja+n-l:ja+n-1)]$ to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix $sub(A)$ is factored as

$$sub(A) = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m (global) INTEGER.
The number of rows to be operated on, that is, the number of rows of the distributed submatrix $sub(A)$. $m \geq 0$.

n (global) INTEGER.

	The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>l</i>	(global) INTEGER. The number of columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$.
<i>a</i>	(local) REAL for pslatz DOUBLE PRECISION for pdlatrz COMPLEX for pclatz COMPLEX*16 for pzlatrz. Pointer into the local memory to an array of $\text{DIMENSION}(lld\_a, LOCc(ja+n-1))$. On entry, the local pieces of the m-by-n distributed matrix $\text{sub}(A)$, which is to be factored.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of $\text{sub}(A)$.
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of $\text{sub}(A)$.
<i>desca</i>	(global and local) INTEGER array of $\text{DIMENSION}(dlen\_)$. The array descriptor for the distributed matrix <i>A</i>.
<i>work</i>	(local) REAL for pslatz DOUBLE PRECISION for pdlatrz COMPLEX for pclatz COMPLEX*16 for pzlatrz. Workspace array, $\text{DIMENSION}(lwork)$. $lwork \geq nq0 + \max(1, mp0)$, where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$, $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$, $mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow)$,

`nq0 = numroc(n+icoff, nb_a, mycol, iacol, npcol)`,
`numroc`, `indxg2p`, and `numroc` are ScaLAPACK tool
functions; `myrow`, `mycol`, `nprow`, and `npcol` can be
determined by calling the subroutine `blacs_gridinfo`.

Output Parameters

<i>a</i>	On exit, the leading m -by- m upper triangular part of <code>sub(A)</code> contains the upper triangular matrix R , and elements $n-l+1$ to n of the first m rows of <code>sub(A)</code> , with the array <i>tau</i> , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.
<i>tau</i>	(local) REAL for <code>pslatz</code> DOUBLE PRECISION for <code>pdlatz</code> COMPLEX for <code>pclatz</code> COMPLEX*16 for <code>pzlatrz</code> . Array, <code>DIMENSION (LOCr(ja+m-1))</code> . This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix A .

Application Notes

The factorization is obtained by Householder's method. The k -th transformation matrix, $Z(k)$, which is used (or, in case of complex routines, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$ -th row of `sub(A)`, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)^H, \quad u(k) = \begin{bmatrix} 1 \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an $(n-m)$ -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar τ is returned in the k -th element of τ and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $z(k)$ are in $a(k, m+1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$.

Z is given by

$$Z = Z(1)Z(2)\dots Z(m).$$

p?lauu2

Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices (local unblocked algorithm).

Syntax

```
call pslauu2(uplo, n, a, ia, ja, desca)
call pdlauu2(uplo, n, a, ia, ja, desca)
call pclauu2(uplo, n, a, ia, ja, desca)
call pzlauu2(uplo, n, a, ia, ja, desca)
```

Description

This routine computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the distributed matrix

$\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $\text{uplo} = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$.

If $\text{uplo} = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this routine, the matrix to operate on should be strictly local to one process.

Input Parameters

uplo (global) CHARACTER*1.

	Specifies whether the triangular factor stored in the <i>matrix</i> sub(<i>A</i>) is upper or lower triangular: = <i>U</i> : upper triangular = <i>L</i> : lower triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$.
<i>a</i>	(local) REAL for <i>pslauu2</i> DOUBLE PRECISION for <i>pdlauu2</i> COMPLEX for <i>pclauu2</i> COMPLEX*16 for <i>pzlauu2</i> . Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, the local pieces of the triangular factor <i>U</i> or <i>L</i> .
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	(local) On exit, if <i>uplo</i> = ' <i>U</i> ', the upper triangle of the distributed matrix sub(<i>A</i>) is overwritten with the upper triangle of the product $U*U'$; if <i>uplo</i> = ' <i>L</i> ', the lower triangle of sub(<i>A</i>) is overwritten with the lower triangle of the product $L*L$.

p?lauum

Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices.

Syntax

```
call pslauum(uplo, n, a, ia, ja, desca)
call pdlauum(uplo, n, a, ia, ja, desca)
call pclauum(uplo, n, a, ia, ja, desca)
call pzlauum(uplo, n, a, ia, ja, desca)
```

Description

This routine computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$. If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

$uplo$	(global) CHARACTER*1. Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular: = 'U': upper triangular = 'L': lower triangular.
n	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$.
a	(local) REAL for pslauum DOUBLE PRECISION for pdlauum COMPLEX for pclauum COMPLEX*16 for pzlauum.

Pointer into the local memory to an array of `DIMENSION(lld_a, LOCC(ja+n-1))`. On entry, the local pieces of the triangular factor U or L .

ia (global) INTEGER.
The row index in the global array A indicating the first row of `sub(A)`.

ja (global) INTEGER.
The column index in the global array A indicating the first column of `sub(A)`.

desca (global and local) INTEGER array of `DIMENSION(dlen_)`.
The array descriptor for the distributed matrix A .

Output Parameters

a (local)
On exit, if `uplo = 'U'`, the upper triangle of the distributed matrix `sub(A)` is overwritten with the upper triangle of the product $U*U'$; if `uplo = 'L'`, the lower triangle of `sub(A)` is overwritten with the lower triangle of the product $L'*L$.

p?lawil

Forms the Wilkinson transform.

Syntax

```
call pslawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pdlawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
```

Description

This routine gets the transform given by $h44$, $h33$, and $h43h34$ into v starting at row m .

Input Parameters

ii (global) INTEGER.
Row owner of $h(m+2, m+2)$.

jj (global) INTEGER.
Column owner of $h(m+2, m+2)$.

m (global) INTEGER.
On entry, the location from where the transform starts (row *m*). Unchanged on exit.

a (global)
REAL for pslawil
DOUBLE PRECISION for pdlawil
Array, DIMENSION (*desca*(*lld_*),*).
On entry, the Hessenberg matrix. Unchanged on exit.

desca (global and local) INTEGER
Array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*. Unchanged on exit.

(global)
REAL for pslawil
h43h34 DOUBLE PRECISION for pdlawil
These three values are for the double shift *QR* iteration.
Unchanged on exit.

Output Parameters

v (global)
REAL for pslawil
DOUBLE PRECISION for pdlawil
Array of size 3 that contains the transform on output.

p?org2l/p?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
call psorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine `p?org2l/p?ung2l` generates an m -by- n real/complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$Q = H(k) * \dots * H(2) * H(1)$ as returned by `p?geqlf`.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $m \geq n \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for <code>psorg2l</code> DOUBLE PRECISION for <code>pdorg2l</code> COMPLEX for <code>pcung2l</code> COMPLEX*16 for <code>pzung2l</code> . Pointer into the local memory to an array, DIMENSION (<code>lld_a</code> , <code>LOCc(ja+n-1)</code>). On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its <i>distributed matrix</i> argument $A(ia:*, ja+n-k:ja+n-1)$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of sub(A).
ja	(global) INTEGER. The column index in the global array A indicating the first column of sub(A).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
The array descriptor for the distributed matrix *A*.

tau (local)
REAL for *psorg2l*
DOUBLE PRECISION for *pdorg2l*
COMPLEX for *pcung2l*
COMPLEX*16 for *pzung2l*.
Array, DIMENSION *LOCc(ja+n-1)*.
This array contains the scalar factor *tau(j)* of the elementary reflector $H(j)$, as returned by [p?geqlf](#).

work (local)
REAL for *psorg2l*
DOUBLE PRECISION for *pdorg2l*
COMPLEX for *pcung2l*
COMPLEX*16 for *pzung2l*.
Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where
 $iroffa = \text{mod}(ia-1, mb\_a),$
 $icoffa = \text{mod}(ja-1, nb\_a),$
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot),$
 $mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow),$
 $nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcot).$
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine [blacs_gridinfo](#).
If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	On exit, this array contains the local pieces of the m -by- n distributed matrix Q .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then <i>info</i> = - ($i*100 + j$), if the i -th argument is a scalar and had an illegal value, then <i>info</i> = - i .

p?org2r/p?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).

Syntax

```
call psorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine p?org2r/p?ung2r generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m :

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?geqrf.

Input Parameters

m (global) INTEGER.

	The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q. $m \geq n \geq 0$.
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. $n \geq k \geq 0$.
<i>a</i>	REAL for psorg2r DOUBLE PRECISION for pdorg2r COMPLEX for pcung2r COMPLEX*16 for pzung2r. Pointer into the local memory to an array, DIMENSION (<i>lld_a</i>, <i>LOCc</i>(<i>ja</i>+<i>n</i>-1)). On entry, the <i>j</i>-th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the <i>k</i> columns of its <i>distributed matrix</i> argument $A(ia:*, ja:ja+k-1)$.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) REAL for psorg2r DOUBLE PRECISION for pdorg2r COMPLEX for pcung2r COMPLEX*16 for pzung2r. Array, DIMENSION <i>LOCc</i>(<i>ja</i>+<i>k</i>-1).

This array contains the scalar factor $\tau(j)$ of the elementary reflector $H(j)$, as returned by [p?geqrf](#). This array is tied to the distributed matrix A .

work (local)
 REAL for psorg2r
 DOUBLE PRECISION for pdorg2r
 COMPLEX for pcung2r
 COMPLEX*16 for pzung2r.
 Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$,
 where
 $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$,
 $mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow)$,
 $nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcot)$.
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a On exit, this array contains the local pieces of the m -by- n distributed matrix Q .

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.

= 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = - (i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

p?orgl2/p?ungl2

Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

```
call psorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine p?orgl2/p?ungl2 generates a m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors),

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors) as returned by p?gelqf.

Input Parameters

m (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.

n (global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.

<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. $m \geq k \geq 0$.
<i>a</i>	REAL for psorgl2 DOUBLE PRECISION for pdorgl2 COMPLEX for pcungl2 COMPLEX*16 for pzungl2. Pointer into the local memory to an array, DIMENSION (<i>lld_a</i>, <i>LOCc(ja+n-1)</i>). On entry, the <i>i</i>-th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the <i>k</i> rows of its <i>distributed matrix</i> argument $A(ia:ia+k-1, ja:*)$.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) REAL for psorgl2 DOUBLE PRECISION for pdorgl2 COMPLEX for pcungl2 COMPLEX*16 for pzungl2. Array, DIMENSION <i>LOCr(ja+k-1)</i>. This array contains the scalar factors <i>tau(i)</i> of the elementary reflectors $H(i)$, as returned by p?gelqf. This array is tied to the distributed matrix <i>A</i>.
<i>WORK</i>	(local) REAL for psorgl2 DOUBLE PRECISION for pdorgl2 COMPLEX for pcungl2 COMPLEX*16 for pzungl2. Workspace array, DIMENSION (<i>lwork</i>).

lwork

(local or global) INTEGER.

The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where

$$iroffa = \text{mod}(ia-1, mb\_a),$$

$$icoffa = \text{mod}(ja-1, nb\_a),$$

$$iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$$

$$iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol),$$

$$mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow),$$

$$nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcol).$$

indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,

then *info* = - (*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

p?orgr2/p?ungr2

Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).

Syntax

```
call psorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Description

The routine p?orgr2/p?ungr2 generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1) * H(2) * \dots * H(k)$ (for real flavors);

$Q = (H(1))^H * (H(2))^H \dots * (H(k))^H$ (for complex flavors) as returned by p?gerqf.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for psorgr2 DOUBLE PRECISION for pdorgr2 COMPLEX for pcungr2

COMPLEX*16 for pzungr2.
 Pointer into the local memory to an array,
 DIMENSION (*lld_a*, *LOCc*(*ja+n-1*)).
 On entry, the *i*-th row must contain the vector that defines
 the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$,
 as returned by [p?gerqf](#) in the *k* rows of its *distributed*
matrix argument $A(ia+m-k:ia+m-1, ja:*)$.

ia (global) INTEGER.
 The row index in the global array *A* indicating the first row
 of sub(*A*).

ja (global) INTEGER.
 The column index in the global array *A* indicating the first
 column of sub(*A*).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *A*.

tau (local)
 REAL for psorgr2
 DOUBLE PRECISION for pdorgr2
 COMPLEX for pcungr2
 COMPLEX*16 for pzungr2.
 Array, DIMENSION *LOCr*(*ja+m-1*). This array contains the
 scalar factors *tau*(*i*) of the elementary reflectors $H(i)$, as
 returned by [p?gerqf](#). This array is tied to the distributed
 matrix *A*.

work (local)
 REAL for psorgr2
 DOUBLE PRECISION for pdorgr2
 COMPLEX for pcungr2
 COMPLEX*16 for pzungr2.
 Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 +$
 $\max(1, mpa0)$, where $iroffa = \text{mod}(ia-1, mb\_a)$,
 $icoffa = \text{mod}(ja-1, nb\_a)$,

```

iarow = indxg2p( ia, mb_a, myrow, rsrc_a, nprow
),
iacol = indxg2p( ja, nb_a, mycol, csrc_a, npcol
),
mpa0 = numroc( m+iroffa, mb_a, myrow, iarow,
nprow ),
nqa0 = numroc( n+icoffa, nb_a, mycol, iacol,
npcol ).

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	On exit, this array contains the local pieces of the m -by- n distributed matrix Q .
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info = - (i*100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?orm2l/p?unm2l

Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
call psorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pcunm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?orm2l/p?unm2l overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1,jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k)*\dots*H(2)*H(1)$ as returned by p?geqlf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER.
 = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,

	= 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. If <i>side</i> = 'L', $m \geq k \geq 0$; if <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l. Pointer into the local memory to an array, DIMENSION(<i>lld_a</i>, <i>LOCc</i>(<i>ja+k-1</i>)). On entry, the <i>j</i>-th row must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If <i>side</i> = 'L', $\text{lld\_a} \geq \max(1, \text{LOCr}(ia+m-1))$, if <i>side</i> = 'R', $\text{lld\_a} \geq \max(1, \text{LOCr}(ia+n-1))$.
<i>ia</i>	(global) INTEGER.

	The row index in the global array <i>A</i> indicating the first row of <i>sub(A)</i> .
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of <i>sub(A)</i> .
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <i>psorm21</i> DOUBLE PRECISION for <i>pdorm21</i> COMPLEX for <i>pcunm21</i> COMPLEX*16 for <i>pzunm21</i> . Array, DIMENSION <i>LOCc(ja+n-1)</i> . This array contains the scalar factor <i>tau(j)</i> of the elementary reflector <i>H(j)</i> , as returned by <i>p?geqlf</i> . This array is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for <i>psorm21</i> DOUBLE PRECISION for <i>pdorm21</i> COMPLEX for <i>pcunm21</i> COMPLEX*16 for <i>pzunm21</i> . Pointer into the local memory to an array, DIMENSION (<i>lld_c</i> , <i>LOCc(jc+n-1)</i>). On entry, the local pieces of the distributed matrix <i>sub(c)</i> .
<i>ic</i>	(global) INTEGER. The row index in the global array <i>c</i> indicating the first row of <i>sub(c)</i> .
<i>jc</i>	(global) INTEGER. The column index in the global array <i>c</i> indicating the first column of <i>sub(c)</i> .
<i>descc</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>c</i> .
<i>work</i>	(local) REAL for <i>psorm21</i> DOUBLE PRECISION for <i>pdorm21</i> COMPLEX for <i>pcunm21</i>

lwork COMPLEX*16 for pzunm2l.
Workspace array, DIMENSION (*lwork*).
On exit, *work*(1) returns the minimal and optimal *lwork*.
(local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least
if *side* = 'L', $lwork \geq mpc0 + \max(1, nqc0)$,
if *side* = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0),$
 $\text{numroc}(\text{numroc}(n+icoffc, nb\_a, 0, 0, npc0),$
 $nb\_a, 0, 0, lcmq))$,
where
 $lcmq = lcm/npcol$,
 $lcm = iclm(nprow, npc0)$,
 $iroffc = \text{mod}(ic-1, mb\_c)$,
 $icoffc = \text{mod}(jc-1, nb\_c)$,
 $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow)$,
 $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npc0)$,
 $Mqc0 = \text{numroc}(m+icoffc, nb\_c, mycol, icrow,$
 $nprow)$,
 $Npc0 = \text{numroc}(n+iroffc, mb\_c, myrow, iccol,$
 $npc0)$,
 $iclm, \text{indxg2p}$, and numroc are ScaLAPACK tool functions;
 $myrow, mycol, nprow$, and $npc0$ can be determined by
calling the subroutine `blacs_gridinfo`.
If *lwork* = -1, then *lwork* is global input and a workspace
query is assumed; the routine only calculates the minimum
and optimal size for all work arrays. Each of these values
is returned in the first entry of the corresponding work array,
and no error message is issued by `pxerbla`.

Output Parameters

c On exit, *c* is overwritten by $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C) /$
 $Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
work On exit, *work*(1) returns the minimal and optimal *lwork*.
info (local) INTEGER.
= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = - (i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, ($mb\_a.eq.mb\_c$.AND. $iroffa.eq.iroffc$.AND. $iarow.eq.icrow$)

If $side = 'R'$, ($mb\_a.eq.nb\_c$.AND. $iroffa.eq.iroffc$).

p?orm2r/p?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf (unblocked algorithm).

Syntax

```
call psorm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```

work, lwork, info)
```

Description

The routine p?orm2r/p?unm2r overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by [p?geqrf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER. = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q. If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psorm2r DOUBLE PRECISION for pdorm2r COMPLEX for pcunm2r

COMPLEX*16 for pzunm2r.
 Pointer into the local memory to an array,
 DIMENSION(*lld_a*, *LOCc*(*ja+k-1*)).
 On entry, the *j*-th column must contain the vector that
 defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$,
 as returned by `p?geqrf` in the *k* columns of its distributed
 matrix argument $A(ia:*, ja:ja+k-1)$. The argument
 $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored
 on exit.

If *side* = 'L', $lld\_a \geq \max(1, LOCr(ia+m-1))$,
 if *side* = 'R', $lld\_a \geq \max(1, LOCr(ia+n-1))$.

ia (global) INTEGER.
 The row index in the global array *A* indicating the first row
 of sub(*A*).

ja (global) INTEGER.
 The column index in the global array *A* indicating the first
 column of sub(*A*).

desca (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *A*.

tau (local)
 REAL for psorm2r
 DOUBLE PRECISION for pdorm2r
 COMPLEX for pcunm2r
 COMPLEX*16 for pzunm2r.
 Array, DIMENSION *LOCc*(*ja+k-1*). This array contains the
 scalar factors *tau*(*j*) of the elementary reflector $H(j)$, as
 returned by `p?geqrf`. This array is tied to the distributed
 matrix *A*.

c (local)
 REAL for psorm2r
 DOUBLE PRECISION for pdorm2r
 COMPLEX for pcunm2r
 COMPLEX*16 for pzunm2r.
 Pointer into the local memory to an array,
 DIMENSION(*lld_c*, *LOCc*(*jc+n-1*)).
 On entry, the local pieces of the distributed matrix sub (*c*).

ic (global) INTEGER.
The row index in the global array *c* indicating the first row of sub(*c*).

jc (global) INTEGER.
The column index in the global array *c* indicating the first column of sub(*c*).

descc (global and local) INTEGER array of DIMENSION (*dlen_*).
The array descriptor for the distributed matrix *c*.

work (local)
REAL for psorm2r
DOUBLE PRECISION for pdorm2r
COMPLEX for pcunm2r
COMPLEX*16 for pzunm2r.
Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least
if *side* = 'L', $lwork \geq mpc0 + \max(1, nqc0)$,
if *side* = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0),$
 $\text{numroc}(\text{numroc}(n+icoffc, nb\_a, 0, 0, npcol),$
 $nb\_a, 0, 0, lcmq)),$
where
 $lcmq = lcm/npcol,$
 $lcm = iclm(nprow, npcol),$
 $iroffc = \text{mod}(ic-1, mb\_c),$
 $icoffc = \text{mod}(jc-1, nb\_c),$
 $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow),$
 $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npcol),$
 $Mqc0 = \text{numroc}(m+icoffc, nb\_c, mycol, icrow,$
 $nprow),$
 $Npc0 = \text{numroc}(n+iroffc, mb\_c, myrow, iccol,$
 $npcol),$
ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions;
myrow, *mycol*, *nprow*, and *npcol* can be determined by
calling the subroutine *blacs_gridinfo*.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q * \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb_a*.eq.*mb_c* .AND. *iroffa*.eq.*iroffc* .AND. *iarow*.eq.*icrow*)

If *side* = 'R', (*mb_a*.eq.*nb_c* .AND. *iroffa*.eq.*iroffc*).

p?orml2/p?unml2

Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

```
call psorml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pdorml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pcunml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)

call pzunml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?orml2/p?unml2 overwrites the general real/complex m -by- n distributed matrix sub (C)=C(ic:ic+m-1, jc:jc+n-1) with

$Q \cdot \text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) \cdot Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k) \cdot \dots \cdot H(2) \cdot H(1)$ (for real flavors)

$Q = (H(k))^H \cdot \dots \cdot (H(2))^H \cdot (H(1))^H$ (for complex flavors)

as returned by p?gelqf . Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

side (global) CHARACTER.

= 'L': apply Q or Q^T for real flavors (Q^H for complex flavors)
 from the left,
 = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors)
 from the right.

trans (global) CHARACTER.
 = 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m (global) INTEGER.
 The number of rows to be operated on, that is, the number
 of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n (global) INTEGER.
 The number of columns to be operated on, that is, the
 number of columns of the distributed submatrix $\text{sub}(C)$. n
 ≥ 0 .

k (global) INTEGER.
 The number of elementary reflectors whose product defines
 the matrix Q .
 If $\text{side} = \text{'L'}$, $m \geq k \geq 0$;
 if $\text{side} = \text{'R'}$, $n \geq k \geq 0$.

a (local)
 REAL for psorml2
 DOUBLE PRECISION for pdorml2
 COMPLEX for pcunml2
 COMPLEX*16 for pzunml2.
 Pointer into the local memory to an array, DIMENSION
 (lld_a , $\text{LOCc}(ja+m-1)$ if $\text{side}=\text{'L'}$,
 (lld_a , $\text{LOCc}(ja+n-1)$ if $\text{side}=\text{'R'}$,
 where $\text{lld\_a} \geq \max(1, \text{LOCr}(ia+k-1))$.
 On entry, the i -th row must contain the vector that defines
 the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as
 returned by [p?gelqf](#) in the k rows of its distributed matrix
 argument $A(ia:ia+k-1, ja:*)$. The argument
 $A(ia:ia+k-1, ja:*)$ is modified by the routine but
 restored on exit.

<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) REAL for psorml2 DOUBLE PRECISION for pdorml2 COMPLEX for pcunml2 COMPLEX*16 for pzunml2. Array, DIMENSION <i>LOCc(ia+k-1)</i>. This array contains the scalar factors <i>tau(i)</i> of the elementary reflector <i>H(i)</i>, as returned by p?gelqf. This array is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) REAL for psorml2 DOUBLE PRECISION for pdorml2 COMPLEX for pcunml2 COMPLEX*16 for pzunml2. Pointer into the local memory to an array, DIMENSION(<i>lld_c</i>, <i>LOCc(jc+n-1)</i>). On entry, the local pieces of the distributed matrix sub (<i>c</i>).
<i>ic</i>	(global) INTEGER. The row index in the global array <i>c</i> indicating the first row of sub(<i>c</i>).
<i>jc</i>	(global) INTEGER. The column index in the global array <i>c</i> indicating the first column of sub(<i>c</i>).
<i>descc</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i>.
<i>work</i>	(local) REAL for psorml2 DOUBLE PRECISION for pdorml2

COMPLEX for pcunml2
 COMPLEX*16 for pzunml2.
 Workspace array, DIMENSION (*lwork*).
lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least
 if *side* = 'L', $lwork \geq mqc0 + \max(\max(1, npc0),$
 $numroc(numroc(m+icoffc, mb\_a, 0, 0, nprow),$
 $mb\_a, 0, 0, lcm)),$
 if *side* = 'R', $lwork \geq npc0 + \max(1, mqc0),$
 where
 $lcmp = lcm / nprow,$
 $lcm = iclm(nprow, npc0),$
 $iroffc = \text{mod}(ic-1, mb\_c),$
 $icoffc = \text{mod}(jc-1, nb\_c),$
 $icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow),$
 $iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npc0),$
 $Mpc0 = numroc(m+icoffc, mb\_c, mycol, icrow,$
 $nprow),$
 $Nqc0 = numroc(n+iroffc, nb\_c, myrow, iccol,$
 $npc0),$
 $iclm, \text{indxg2p}$ and $numroc$ are ScaLAPACK tool functions;
 $myrow, mycol, nprow,$ and $npc0$ can be determined by
 calling the subroutine `blacs_gridinfo`.
 If *lwork* = -1, then *lwork* is global input and a workspace
 query is assumed; the routine only calculates the minimum
 and optimal size for all work arrays. Each of these values
 is returned in the first entry of the corresponding work array,
 and no error message is issued by `pxerbla`.

Output Parameters

c On exit, *c* is overwritten by $Q^* \text{sub}(C)$, or $Q^T \text{sub}(C) /$
 $Q^H \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
work On exit, *work*(1) returns the minimal and optimal *lwork*.
info (local) INTEGER.
 = 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,
then $info = - (i*100+j)$,
if the i -th argument is a scalar and had an illegal value,
then $info = -i$.

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, $(nb\_a.eq.mb\_c .AND. icoffa.eq.iroffc)$

If $side = 'R'$, $(nb\_a.eq.nb\_c .AND. icoffa.eq.icoffc .AND. iacol.eq.iccol)$.

p?ormr2/p?unmr2

Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).

Syntax

```
call psormr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pdormr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pcunmr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

```
call pzunmr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc,
work, lwork, info)
```

Description

The routine p?ormr2/p?unmr2 overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) * H(2) * \dots * H(k)$ (for real flavors)

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors)

as returned by [p?gerqf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER. = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER. = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psormr2

DOUBLE PRECISION for pdormr2
 COMPLEX for pcunmr2
 COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array, DIMENSION

(lld_a, LOCc(ja+m-1) if side='L',
 (lld_a, LOCc(ja+n-1) if side='R',

where $lld\_a \geq \max(1, LOCr(ia+k-1))$.

On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gerqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

The argument $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia

(global) INTEGER.

The row index in the global array A indicating the first row of sub(A).

ja

(global) INTEGER.

The column index in the global array A indicating the first column of sub(A).

desca

(global and local) INTEGER array of DIMENSION ($dlen\_$).

The array descriptor for the distributed matrix A .

tau

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Array, DIMENSION $LOCc(ia+k-1)$. This array contains the scalar factors $tau(i)$ of the elementary reflector $H(i)$, as returned by [p?gerqf](#). This array is tied to the distributed matrix A .

c

(local)

REAL for psormr2

DOUBLE PRECISION for pdormr2

COMPLEX for pcunmr2

COMPLEX*16 for pzunmr2.

Pointer into the local memory to an array,
 DIMENSION(*lld_c*, *LOCc(jc+n-1)*). On entry, the local
 pieces of the distributed matrix sub (*c*).

ic (global) INTEGER.
 The row index in the global array *c* indicating the first row
 of sub(*c*).

jc (global) INTEGER.
 The column index in the global array *c* indicating the first
 column of sub(*c*).

descc (global and local) INTEGER array of DIMENSION (*dlen_*).
 The array descriptor for the distributed matrix *c*.

work (local)
 REAL for psormr2
 DOUBLE PRECISION for pdormr2
 COMPLEX for pcunmr2
 COMPLEX*16 for pzunmr2.
 Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least

```

if side = 'L', lwork ≥ mpc0 + max(max(1, nqc0),
numroc(numroc(m+iroffc, mb_a, 0, 0, nprow),
mb_a, 0, 0, lcmp)),
if side = 'R', lwork ≥ nqc0 + max(1, mpc0),
where lcmp = lcm/nprow,
lcm = iclm(nprow, npc0),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc0),
Mpc0 = numroc(m+iroffc, mb_c, myrow, icrow,
nprow),
Nqc0 = numroc(n+icoffc, nb_c, mycol, iccol,
npc0),

```

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the subroutine `blacs_gridinfo`.
 If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	On exit, <code>c</code> is overwritten by $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$
<code>work</code>	On exit, <code>work(1)</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <code>info</code> = - (i*100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = -i.

NOTE. The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If `side = 'L'`, (`nb_a.eq.mb_c .AND. icoffa.eq.iroffc`)

If `side = 'R'`, (`nb_a.eq.nb_c .AND. icoffa.eq.icoffc .AND. iacol.eq.iccol`).

p?pbtrsv

*Solves a single triangular linear system via
frontsolve or backsolve where the triangular matrix
is a factor of a banded matrix computed by
p?pbtrf.*

Syntax

```
call pspbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)
```

```
call pdpbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)
```

```
call pcpbtrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)
```

```
call pzpbttrsv(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)
```

Description

The routine p?pbtrsv solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Cholesky factorization code p?pbtrf and is stored in $A(1:n, ja:ja+n-1)$ and *af*. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*.

Routine p?pbtrf must be called first.

Input Parameters

uplo (global) CHARACTER. Must be 'U' or 'L'.
If *uplo* = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;
If *uplo* = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

<i>trans</i>	(global) CHARACTER. Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$. If <i>trans</i> = 'C' for complex flavors, solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.
<i>bw</i>	(global) INTEGER. The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$.
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.
<i>a</i>	(local) REAL for pspbtrsv DOUBLE PRECISION for pdpbtrsv COMPLEX for pcpbtrsv COMPLEX*16 for pzpbtrsv. Pointer into the local memory to an array with the first DIMENSION $lld\_a \geq (bw+1)$, stored in <i>desca</i>. On entry, this array contains the local pieces of the n-by-n symmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i>.

	If 1D type (<i>dtype_a</i> = 501), then <i>dlen</i> ≥ 7; If 2D type (<i>dtype_a</i> = 1), then <i>dlen</i> ≥ 9. Contains information on mapping of <i>A</i> to memory. (See ScaLAPACK manual for full description and options.)
<i>b</i>	(local) REAL for pspbtrsv DOUBLE PRECISION for pdpbtrsv COMPLEX for pcpbtrsv COMPLEX*16 for pzpbtrsv. Pointer into the local memory to an array of local lead DIMENSION <i>lld_b</i> ≥ <i>nb</i>. On entry, this array contains the local pieces of the right hand sides <i>B</i>(<i>jb:jb+n-1</i>, 1:<i>nrhs</i>).
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i>. If 1D type (<i>dtype_b</i> = 502), then <i>dlen</i> ≥ 7; If 2D type (<i>dtype_b</i> = 1), then <i>dlen</i> ≥ 9. Contains information on mapping of <i>B</i> to memory. Please, see ScaLAPACK manual for full description and options.
<i>laf</i>	(local) INTEGER. The size of user-input auxiliary Fillin space <i>af</i>. Must be <i>laf</i> ≥ (<i>nb</i>+2*<i>bw</i>)*<i>bw</i>. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>(1).
<i>work</i>	(local) REAL for pspbtrsv DOUBLE PRECISION for pdpbtrsv COMPLEX for pcpbtrsv COMPLEX*16 for pzpbtrsv. The array <i>work</i> is a temporary workspace array of DIMENSION <i>lwork</i>. This space may be overwritten in between calls to routines.

lwork (local or global) INTEGER. The size of the user-input workspace *work*, must be at least $lwork \geq bw * nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

af (local)
 REAL for pspbtrsv
 DOUBLE PRECISION for pdpbtrsv
 COMPLEX for pcgbtrsv
 COMPLEX*16 for pzgbtrsv.
 The array *af* is of DIMENSION *laf*. It contains auxiliary Fillin space. Fillin is created during the factorization routine *p?pbtrf* and this is stored in *af*. If a linear system is to be solved using *p?pbtrs* after the factorization routine, *af* must not be altered after the factorization.

b On exit, this array contains the local piece of the solutions distributed matrix *x*.

work(1) On exit, *work*(1) contains the minimum value of *lwork*.

info (local) INTEGER.
 = 0: successful exit
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
 then *info* = $-(i*100+j)$,
 if the *i*-th argument is a scalar and had an illegal value,
 then *info* = $-i$.

Application Notes

If the factorization routine and the solve routine are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization routine and the solve routine.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case $N/P \gg bw$ are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix A one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into P pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

- 1. Local Phase:** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space af . Mathematically, this is equivalent to reordering the matrix A as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of A in memory.
- 2. Reduced System Phase:** A small $(bw * (P-1))$ system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space af . A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
- 3. Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

p?pttrsv

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf.

Syntax

```
call pspttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pdpttrsv(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pcpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

call pzpttrsv(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
```

Description

This routine solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code [p?pttrf](#) and is stored in $A(1:n, ja:ja+n-1)$ and *af*. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*.

Routine [p?pttrf](#) must be called first.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) CHARACTER. Must be 'N' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'C' (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.
<i>nrhs</i>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.
<i>d</i>	(local) REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv

	COMPLEX*16 for pzpttrsv. Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq \text{desca}(nb\_)$.
<i>e</i>	(local) REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv COMPLEX*16 for pzpttrsv. Pointer to the local part of the global vector storing the upper diagonal of the matrix; must be of size $\geq \text{desca}(nb\_)$. Globally, $du(n)$ is not referenced, and du must be aligned with d .
<i>ja</i>	(global) INTEGER. The index in the global array A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix A . If 1D type ($dtype\_a = 501$ or 502), then $dlen \geq 7$; If 2D type ($dtype\_a = 1$), then $dlen \geq 9$. Contains information on mapping of A to memory. See ScaLAPACK manual for full description and options.
<i>b</i>	(local) REAL for pspttrsv DOUBLE PRECISION for pdpttrsv COMPLEX for pcpttrsv COMPLEX*16 for pzpttrsv. Pointer into the local memory to an array of local lead DIMENSION $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
<i>descb</i>	(global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix B .

If 1D type ($dtype\_b = 502$), then $dlen \geq 7$;

If 2D type ($dtype\_b = 1$), then $dlen \geq 9$.

Contains information on mapping of B to memory. See ScaLAPACK manual for full description and options.

laf

(local)

INTEGER. The size of user-input auxiliary Fillin space *af*.

Must be $laf \geq (nb+2*bw)*bw$.

If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

The array *work* is a temporary workspace array of DIMENSION *lwork*. This space may be overwritten in between calls to routines.

lwork

(local or global) INTEGER. The size of the user-input

workspace *work*, must be at least $lwork \geq (10+2*\min(100, nrhs))*npcol+4*nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work*(1) and an error code is returned.

Output Parameters

d, e

(local).

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

On exit, these arrays contain information on the factors of the matrix.

af

(local)

REAL for pspttrsv

DOUBLE PRECISION for pdpttrsv

COMPLEX for pcpttrsv

COMPLEX*16 for pzpttrsv.

	The array <i>af</i> is of DIMENSION <i>laaf</i> . It contains auxiliary Fillin space. Fillin is created during the factorization routine <i>p?pbtrf</i> and this is stored in <i>af</i> . If a linear system is to be solved using <i>p?pttrs</i> after the factorization routine, <i>af</i> must not be altered after the factorization.
<i>b</i>	On exit, this array contains the local piece of the solutions distributed matrix <i>x</i> .
<i>work</i> (1)	On exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

p?potf2

Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).

Syntax

```
call pspotf2(uplo, n, a, ia, ja, desca, info)
call pdpotf2(uplo, n, a, ia, ja, desca, info)
call pcpotf2(uplo, n, a, ia, ja, desca, info)
call pzpotf2(uplo, n, a, ia, ja, desca, info)
```

Description

This routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix sub (A)=A(ia:ia+n-1, ja:ja+n-1).

The factorization has the form

sub (A) = U'^*U , if *uplo* = 'U', or sub (A) = L^*L' , if *uplo* = 'L',

where *U* is an upper triangular matrix, *L* is lower triangular. X' denotes transpose (conjugate transpose) of *x*.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix <i>A</i> is stored. = 'U': upper triangle of sub (<i>A</i>) is stored; = 'L': lower triangle of sub (<i>A</i>) is stored.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix sub (<i>A</i>). $n \geq 0$.
<i>a</i>	(local) REAL for pspotf2 DOUBLE PRECISION or pdpotf2 COMPLEX for pcpotf2 COMPLEX*16 for pzpotf2. Pointer into the local memory to an array of <code>DIMENSION(11d_a, LOCC(ja+n-1))</code> containing the local pieces of the <i>n</i>-by-<i>n</i> symmetric distributed matrix sub(<i>A</i>) to be factored. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular matrix and the strictly upper triangular part of sub(<i>A</i>) is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code>. The array descriptor for the distributed matrix <i>A</i>.

Output Parameters

<i>a</i>	(local) On exit, if <i>uplo</i> = 'U', the upper triangular part of the distributed matrix contains the Cholesky factor <i>U</i>;

if `uplo = 'L'`, the lower triangular part of the distributed matrix contains the Cholesky factor L .

`info` (local) INTEGER.
 = 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then `info` = $-(i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then `info` = $-i$.
 > 0: if `info` = k , the leading minor of order k is not positive definite, and the factorization could not be completed.

p?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
call psrscl(n, sa, sx, ix, jx, descx, incx)
call pdrscl(n, sa, sx, ix, jx, descx, incx)
call pcsrscl(n, sa, sx, ix, jx, descx, incx)
call pzdrscl(n, sa, sx, ix, jx, descx, incx)
```

Description

This routine multiplies an n -element real/complex vector `sub(x)` by the real scalar $1/a$. This is done without overflow or underflow as long as the final result `sub(x)/a` does not overflow or underflow.

`sub(x)` denotes `x(ix:ix+n-1, jx:jx)`, if `incx` = 1,

and `x(ix:ix, jx:jx+n-1)`, if `incx` = `m_x`.

Input Parameters

`n` (global) INTEGER.
 The number of components of the distributed vector `sub(x)`.
 $n \geq 0$.

<i>sa</i>	REAL for psrcsl/pcsrcsl DOUBLE PRECISION for pdrsl/pzdrsl. The scalar <i>a</i> that is used to divide each component of the vector <i>x</i>. This parameter must be ≥ 0.
<i>sx</i>	REAL for psrcsl DOUBLE PRECISION for pdrsl COMPLEX for pcsrcsl COMPLEX*16 for pzdrsl. Array containing the local pieces of a distributed matrix of DIMENSION of at least $((j_x-1)*m_x + i_x + (n-1)*abs(incx))$. This array contains the entries of the distributed vector sub(<i>x</i>).
<i>ix</i>	(global) INTEGER. The row index of the submatrix of the distributed matrix <i>x</i> to operate on.
<i>jx</i>	(global) INTEGER. The column index of the submatrix of the distributed matrix <i>x</i> to operate on.
<i>descx</i>	(global and local). INTEGER. Array of DIMENSION 8. The array descriptor for the distributed matrix <i>x</i>.
<i>incx</i>	(global) INTEGER. The increment for the elements of <i>x</i>. This version supports only two values of <i>incx</i>, namely 1 and m_x.

Output Parameters

<i>sx</i>	On exit, the result x/a .

p?sygs2/p?hegs2

Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).

Syntax

```
call pssygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pdsygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pchegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pzhegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
```

Description

The routine p?sygs2/p?hegs2 reduces a real symmetric-definite or a complex Hermitian-definite generalized eigenproblem to standard form.

Here $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$, and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $\text{ibtype} = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and $\text{sub}(A)$ is overwritten by

$$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U) \text{ or } \text{inv}(L) * \text{sub}(A) * \text{inv}(L^T) \quad - \text{ for real flavors, and}$$

$$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U) \text{ or } \text{inv}(L) * \text{sub}(A) * \text{inv}(L^H) \quad - \text{ for complex flavors.}$$

If $\text{ibtype} = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and $\text{sub}(A)$ is overwritten by

$$U * \text{sub}(A) * U^T \text{ or } L * T * \text{sub}(A) * L \quad - \text{ for real flavors and}$$

$$U * \text{sub}(A) * U^H \text{ or } L * H * \text{sub}(A) * L \quad - \text{ for complex flavors.}$$

The matrix $\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L * L^T$ (for real flavors), or as $U^H * U$ or $L * L^H$ (for complex flavors) by p?potrf.

Input Parameters

<i>ibtype</i>	(global) INTEGER. = 1: compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real subroutines, and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ for complex subroutines; = 2 or 3: compute $U * \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$ for real subroutines, and $U * \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$ for complex subroutines.
<i>uplo</i>	(global) CHARACTER Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored, and how $\text{sub}(B)$ is factorized. = 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $U^T * U$ (for real subroutines) or as $U^H * U$ (for complex subroutines). = 'L': Lower triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $L * L^T$ (for real subroutines) or as $L * L^H$ (for complex subroutines)
<i>n</i>	(global) INTEGER. The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$. $n \geq 0$.
<i>a</i>	(local) REAL for pssygs2 DOUBLE PRECISION for pdsygs2 COMPLEX for pchezs2 COMPLEX*16 for pzhezs2. Pointer into the local memory to an array, $\text{DIMENSION}(\text{lld\_a}, \text{LOCc}(ja+n-1))$. On entry, this array contains the local pieces of the n-by-n symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

	If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(<i>A</i>) is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>B</i>	(local) REAL for pssygs2 DOUBLE PRECISION for pdsygs2 COMPLEX for pcheqs2 COMPLEX*16 for pzheqs2. Pointer into the local memory to an array, DIMENSION(<i>lld_b</i> , <i>LOCc(jb+n-1)</i>). On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of sub(<i>B</i>) as returned by <i>p?potrf</i> .
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of the sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	(local) On exit, if <i>info</i> = 0, the transformed matrix is stored in the same format as sub(<i>A</i>).
<i>info</i>	INTEGER. = 0: successful exit. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?sytd2/p?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

```
call pssytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pchetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Description

The routine p?sytd2/p?hetd2 reduces a real symmetric/complex Hermitian matrix sub(*A*) to symmetric/Hermitian tridiagonal form *T* by an orthogonal/unitary similarity transformation:

$Q^* \text{sub}(A) Q = T$, where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix sub(<i>A</i>) is stored: = 'U': upper triangular = 'L': lower triangular
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix sub(<i>A</i>). $n \geq 0$.
<i>a</i>	(local) REAL for pssytd2 DOUBLE PRECISION for pdsytd2 COMPLEX for pchetd2 COMPLEX*16 for pzhetd2. Pointer into the local memory to an array, DIMENSION(<i>lld_a</i> , <i>LOCc</i> (<i>ja</i> + <i>n</i> -1)).

On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$.
 If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.
 If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja (global) INTEGER.
 The row and column indices in the global array A indicating the first row and the first column of the $\text{sub}(A)$, respectively.

desca (global and local) INTEGER array, DIMENSION ($dlen\_$). The array descriptor for the distributed matrix A .

work (local)
 REAL for pssytd2
 DOUBLE PRECISION for pdsytd2
 COMPLEX for pchetd2
 COMPLEX*16 for pzhetd2.
 The array *work* is a temporary workspace array of
 DIMENSION $lwork$.

Output Parameters

a On exit, if $\text{uplo} = 'U'$, the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors;
 if $\text{uplo} = 'L'$, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors. See the *Application Notes* below.

d (local)
 REAL for pssytd2/pchetd2
 DOUBLE PRECISION for pdsytd2/pzhetd2.

	Array, $\text{DIMENSION}(\text{LOCc}(ja+n-1))$. The diagonal elements of the tridiagonal matrix T: $d(i) = a(i, i)$; d is tied to the distributed matrix A.
<i>e</i>	(local) REAL for pssytd2/pchetd2 DOUBLE PRECISION for pdsytd2/pzhetd2. Array, $\text{DIMENSION}(\text{LOCc}(ja+n-1))$, if <i>uplo</i> = 'U', $\text{LOCc}(ja+n-2)$ otherwise. The off-diagonal elements of the tridiagonal matrix T: $e(i) = a(i, i+1)$ if <i>uplo</i> = 'U', $e(i) = a(i+1, i)$ if <i>uplo</i> = 'L'. e is tied to the distributed matrix A.
<i>tau</i>	(local) REAL for pssytd2 DOUBLE PRECISION for pdsytd2 COMPLEX for pchetd2 COMPLEX*16 for pzhetd2. Array, $\text{DIMENSION}(\text{LOCc}(ja+n-1))$. The scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix A.
<i>work</i> (1)	On exit, <i>work</i>(1) returns the minimal and optimal value of <i>lwork</i>.
<i>lwork</i>	(local or global) INTEGER. The dimension of the workspace array <i>work</i>. <i>lwork</i> is local input and must be at least $lwork \geq 3n$. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then <i>info</i> = $-(i*100)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $TAU(ja+i-1)$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $TAU(ja+i-1)$.

The contents of sub (A) on exit are illustrated by the following examples with $n = 5$:

$$\begin{array}{cc} \text{if } uplo='U': & \text{if } uplo='L': \\ \begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix} & \begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix} \end{array}$$

where d and e denotes diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

NOTE. The distributed submatrix sub(A) must verify some alignment properties, namely the following expression should be true:

($mb\_a.eq.nb\_a$.AND. $iroffa.eq.icoffa$) with $iroffa = \text{mod}(ia - 1, mb\_a)$
and $icoffa = \text{mod}(ja - 1, nb\_a)$.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

```
call pstrti2(uplo, diag, n, a, ia, ja, desca, info)
call pdtrti2(uplo, diag, n, a, ia, ja, desca, info)
call pctrti2(uplo, diag, n, a, ia, ja, desca, info)
call pztrti2(uplo, diag, n, a, ia, ja, desca, info)
```

Description

This routine computes the inverse of a real/complex upper or lower triangular block matrix sub (A) = A(ia:ia+n-1, ja:ja+n-1).

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the matrix sub (A) is upper or lower triangular. = 'U': sub (A) is upper triangular = 'L': sub (A) is lower triangular.
<i>diag</i>	(global) CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': sub (A) is non-unit triangular = 'U': sub (A) is unit triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub (A). $n \geq 0$.
<i>a</i>	(local) REAL for pstrti2 DOUBLE PRECISION for pdtrti2 COMPLEX for pctrti2 COMPLEX*16 for pztrti2.

Pointer into the local memory to an array,

`DIMENSION(lld_a, LOCC(ja+n-1)).`

On entry, this array contains the local pieces of the triangular matrix $\text{sub}(A)$.

If `uplo = 'U'`, the leading n -by- n upper triangular part of the matrix $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If `uplo = 'L'`, the leading n -by- n lower triangular part of the matrix $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. If `diag = 'U'`, the diagonal elements of $\text{sub}(A)$ are not referenced either and are assumed to be 1.

`ia, ja`

(global) `INTEGER`.

The row and column indices in the global array `A` indicating the first row and the first column of the $\text{sub}(A)$, respectively.

`desca`

(global and local) `INTEGER` array, `DIMENSION(dlen_)`. The array descriptor for the distributed matrix `A`.

Output Parameters

`a`

On exit, the (triangular) inverse of the original matrix, in the same storage format.

`info`

`INTEGER`.

= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value,

then `info = - (i*100)`,

if the i -th argument is a scalar and had an illegal value,

then `info = -i`.

slamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

```
call slamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
call dlamsh(s, lds, nbulge, jblk, h, ldh, n, ulp)
```

Description

This routine sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The subroutine should only be called when there are multiple shifts/bulges (*nbulge* > 1) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

<i>s</i>	(local) INTEGER. REAL for slamsh DOUBLE PRECISION for dlamsh Array, DIMENSION (<i>lds</i> ,*). On entry, the matrix of shifts. Only the 2x2 diagonal of <i>s</i> is referenced. It is assumed that <i>s</i> has <i>jblk</i> double shifts (size 2).
<i>lds</i>	(local) INTEGER. On entry, the leading dimension of <i>s</i> ; unchanged on exit. $1 < nbulge \leq jblk \leq lds/2$.
<i>nbulge</i>	(local) INTEGER. On entry, the number of bulges to send through <i>h</i> (>1). <i>nbulge</i> should be less than the maximum determined (<i>jblk</i>). $1 < nbulge \leq jblk \leq lds/2$.
<i>jblk</i>	(local) INTEGER. On entry, the leading dimension of <i>s</i> ; unchanged on exit.
<i>h</i>	(local) INTEGER.

REAL for slamsh
 DOUBLE PRECISION for dlamsh
 Array, DIMENSION (*lds*, *n*).
 On entry, the local matrix to apply the shifts on.
h should be aligned so that the starting row is 2.

ldh (local)
 INTEGER.
 On entry, the leading dimension of *H*; unchanged on exit.

n (local) INTEGER.
 On entry, the size of *H*. If all the bulges are expected to go through, *n* should be at least $4nbulge+2$. Otherwise, *nbulge* may be reduced by this routine.

ulp (local)
 REAL for slamsh
 DOUBLE PRECISION for dlamsh
 On entry, machine precision. Unchanged on exit.

Output Parameters

s On exit, the data is rearranged in the best order for applying.

nbulge On exit, the maximum number of bulges that can be sent through.

h On exit, the data is destroyed.

?laref

Applies Householder reflectors to matrices on either their rows or columns.

Syntax

```
call slaref(type, a, lda, wantz, z, ldz, block, irow1, icol1, istart, istop,
itmp1, itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3)

call dlaref(type, a, lda, wantz, z, ldz, block, irow1, icol1, istart, istop,
itmp1, itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3)
```

Description

This routine applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

<i>type</i>	(global) CHARACTER*1. If <i>type</i> = 'R', apply reflectors to the rows of the matrix (apply from left). Otherwise, apply reflectors to the columns of the matrix. Unchanged on exit.
<i>a</i>	(global) REAL for <i>sref</i> DOUBLE PRECISION for <i>dlaref</i> Array, DIMENSION (<i>lda</i> , *). On entry, the matrix to receive the reflections.
<i>lda</i>	(local) INTEGER. On entry, the leading dimension of <i>A</i> ; unchanged on exit.
<i>wantz</i>	(global) LOGICAL. If <i>wantz</i> = .TRUE., apply any column reflections to <i>Z</i> as well. If <i>wantz</i> = .FALSE., do no additional work on <i>Z</i> .
<i>z</i>	(global) REAL for <i>sref</i> DOUBLE PRECISION for <i>dlaref</i> Array, DIMENSION (<i>ldz</i> , *). On entry, the second matrix to receive column reflections.
<i>ldz</i>	(local) INTEGER. On entry, the leading dimension of <i>Z</i> ; unchanged on exit.
<i>block</i>	(global). LOGICAL. = .TRUE. : apply several reflectors at once and read their data from the <i>vecs</i> array; = .FALSE. : apply the single reflector given by <i>v2</i> , <i>v3</i> , <i>t1</i> , <i>t2</i> , and <i>t3</i> .
<i>irow1</i>	(local) INTEGER. On entry, the local row element of the matrix <i>A</i> .
<i>icol1</i>	(local) INTEGER. On entry, the local column element of the matrix <i>A</i> .
<i>istart</i>	(global) INTEGER.

	Specifies the "number" of the first reflector. <i>istart</i> is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istart</i> is ignored if <i>block</i> is <code>.FALSE.</code> .
<i>istop</i>	(global) INTEGER. Specifies the "number" of the last reflector. <i>istop</i> is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istop</i> is ignored if <i>block</i> is <code>.FALSE.</code> .
<i>itmp1</i>	(local) INTEGER. Starting range into <i>A</i> . For rows, this is the local first column. For columns, this is the local first row.
<i>itmp2</i>	(local) INTEGER. Ending range into <i>A</i> . For rows, this is the local last column. For columns, this is the local last row.
<i>liloz, lihi</i>	(local). INTEGER. Serve the same purpose as <i>itmp1</i> , <i>itmp2</i> but for <i>Z</i> when <i>wantz</i> is set.
<i>vecs</i>	(global) REAL for <code>slaref</code> DOUBLE PRECISION for <code>dlaref</code> . Array of size $3 * n$ (matrix size). This array holds the size 3 reflectors one after another and is only accessed when <i>block</i> is <code>.TRUE.</code> .
<i>v2,v3,t1,t2,t3</i>	(global). INTEGER. REAL for <code>slaref</code> DOUBLE PRECISION for <code>dlaref</code> . These parameters hold information on a single size 3 Householder reflector and are read when <i>block</i> is <code>.FALSE.</code> , and overwritten when <i>block</i> is <code>.TRUE.</code> .

Output Parameters

<i>a</i>	On exit, the updated matrix.
<i>z</i>	Changed only if <i>wantz</i> is set. If <i>wantz</i> is <code>.FALSE.</code> , <i>z</i> is not referenced.
<i>irow1</i>	Undefined.
<i>icol1</i>	Undefined.

v2,v3,t1,t2,t3

These parameters are read when *block* is `.FALSE.`, and overwritten when *block* is `.TRUE.`.

?lasorte

Sorts eigenpairs by real and complex data types.

Syntax

```
call slasorte(s, lds, j, out, info)
```

```
call dlasorte(s, lds, j, out, info)
```

Description

This routine sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This routine does no parallel work and makes no calls.

Input Parameters

<i>s</i>	(local) INTEGER. REAL for <code>slasorte</code> DOUBLE PRECISION for <code>dlasorte</code> Array, DIMENSION (<i>lds</i>). On entry, a matrix already in Schur form.
<i>lds</i>	(local) INTEGER. On entry, the leading dimension of the array <i>s</i> ; unchanged on exit.
<i>j</i>	(local) INTEGER. On entry, the order of the matrix <i>s</i> ; unchanged on exit.
<i>out</i>	(local) INTEGER. REAL for <code>slasorte</code> DOUBLE PRECISION for <code>dlasorte</code> Array, DIMENSION (2*j). The work buffer required by the routine.
<i>info</i>	(local) INTEGER.

Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix s was not originally in Schur form. 0 indicates successful completion.

Output Parameters

s On exit, the diagonal blocks of s have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.

out Work buffer.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt2(id, n, d, key, info)
call dlasrt2(id, n, d, key, info)
```

Description

This routine is modified LAPACK routine [?lasrt](#), which sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of `STACK` limits n to about 2^{32} .

Input Parameters

id CHARACTER*1.
= 'I': sort d in increasing order;
= 'D': sort d in decreasing order.

n INTEGER. The length of the array d .

d REAL for `slasrt2`
DOUBLE PRECISION for `dlasrt2`.
Array, DIMENSION (n).
On entry, the array to be sorted.

key INTEGER.
Array, DIMENSION (n).

On entry, *key* contains a key to each of the entries in *d()*.
Typically, $key(i) = i$ for all *i*.

Output Parameters

<i>D</i>	On exit, <i>d</i> has been sorted into increasing order ($d(1) \leq \dots \leq d(n)$) or into decreasing order ($d(1) \geq \dots \geq d(n)$), depending on <i>id</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = -i, the <i>i</i> -th argument had an illegal value.
<i>key</i>	On exit, <i>key</i> is permuted in exactly the same manner as <i>d()</i> was permuted from input to output. Therefore, if $key(i)$ = <i>i</i> for all <i>i</i> upon input, then $d_{out}(i) = d_{in}(key(i))$.

?stein2

*Computes the eigenvectors corresponding to
specified eigenvalues of a real symmetric
tridiagonal matrix, using inverse iteration.*

Syntax

```
call sstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail,
info)
call dstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail,
info)
```

Description

This routine is a modified LAPACK routine [?stein](#). It computes the eigenvectors of a real symmetric tridiagonal matrix *T* corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>T</i> ($n \geq 0$).

<i>m</i>	INTEGER. The number of eigenvectors to be found ($0 \leq m \leq n$).
<i>d</i> , <i>e</i> , <i>w</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i>(*), DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>. <i>e</i>(*), DIMENSION (<i>n</i>). The (<i>n</i>-1) subdiagonal elements of the tridiagonal matrix <i>T</i>, in elements 1 to <i>n</i>-1. <i>e</i>(<i>n</i>) need not be set. <i>w</i>(*), DIMENSION (<i>n</i>). The first <i>m</i> elements of <i>w</i> contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array <i>w</i> from ?stebz with ORDER = 'B' is expected here). The dimension of <i>w</i> must be at least $\max(1, n)$.
<i>iblock</i>	INTEGER. Array, DIMENSION (<i>n</i>). The submatrix indices associated with the corresponding eigenvalues in <i>w</i> ; <i>iblock</i>(<i>i</i>) = 1, if eigenvalue <i>w</i>(<i>i</i>) belongs to the first submatrix from the top, <i>iblock</i>(<i>i</i>) = 2, if eigenvalue <i>w</i>(<i>i</i>) belongs to the second submatrix, etc. (The output array <i>iblock</i> from ?stebz is expected here).
<i>isplit</i>	INTEGER. Array, DIMENSION (<i>n</i>). The splitting points, at which <i>T</i> breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i>(1), the second submatrix consists of rows/columns <i>isplit</i>(1)+1 through <i>isplit</i>(2), etc. (The output array <i>isplit</i> from ?stebz is expected here).
<i>orfac</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within $orfac * T$ of each other are to be orthogonalized.

<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> $\geq \max(1, n)$.
<i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Workspace array, DIMENSION (5 <i>n</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>).

Output Parameters

<i>z</i>	REAL for sstein2 DOUBLE PRECISION for dstein2 Array, DIMENSION (<i>ldz</i> , <i>m</i>). The computed eigenvectors. The eigenvector associated with the eigenvalue $w(i)$ is stored in the <i>i</i> -th column of <i>z</i> . Any vector that fails to converge is set to its current iterate after <i>maxits</i> iterations.
<i>ifail</i>	INTEGER. Array, DIMENSION (<i>m</i>). On normal exit, all elements of <i>ifail</i> are zero. If one or more eigenvectors fail to converge after <i>maxits</i> iterations, then their indices are stored in the array <i>ifail</i> .
<i>info</i>	INTEGER. <i>info</i> = 0, the exit is successful. <i>info</i> < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th had an illegal value. <i>info</i> > 0: if <i>info</i> = <i>i</i> , then <i>i</i> eigenvectors failed to converge in <i>maxits</i> iterations. Their indices are stored in the array <i>ifail</i> .

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

```
call sdbtf2(m, n, kl, ku, ab, ldab, info)
call ddbtf2(m, n, kl, ku, ab, ldab, info)
call cdbtf2(m, n, kl, ku, ab, ldab, info)
call zdbtf2(m, n, kl, ku, ab, ldab, info)
```

Description

This routine computes an *LU* factorization of a general real/complex *m*-by-*n* band matrix *A* without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>A</i> ($n \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab</i>	REAL for sdbtf2 DOUBLE PRECISION for ddbtf2 COMPLEX for cdbtf2 COMPLEX*16 for zdbtf2. Array, DIMENSION (<i>ldab</i>, <i>n</i>). The matrix <i>A</i> in band storage, in rows <i>kl</i>+1 to <i>2kl</i>+<i>ku</i>+1; rows 1 to <i>kl</i> of the array need not be set. The <i>j</i>-th column of <i>A</i> is stored in the <i>j</i>-th column of the array <i>ab</i> as follows: $ab(kl+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.

ldab INTEGER. The leading dimension of the array *ab*.
($ldab \geq 2kl + ku + 1$)

Output Parameters

ab On exit, details of the factorization: *u* is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the *Application Notes* below for further details.

info INTEGER.
= 0: successful exit
< 0: if *info* = - *i*, the *i*-th argument had an illegal value,
> 0: if *info* = + *i*, *u*(*i*,*i*) is 0. The factorization has been completed, but the factor *u* is exactly singular. Division by 0 will occur if you use the factor *u* for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

on entry	on exit
$\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$	$\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$

The routine does not use array elements marked *; elements marked + need not be set on entry, but the routine requires them to store elements of *u*, because of fill-in resulting from the row interchanges.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdbtrf(m, n, kl, ku, ab, ldab, info)
call ddbtrf(m, n, kl, ku, ab, ldab, info)
call cdbtrf(m, n, kl, ku, ab, ldab, info)
call zdbtrf(m, n, kl, ku, ab, ldab, info)
```

Description

This routine computes an LU factorization of a real m -by- n band matrix A without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
kl	INTEGER. The number of sub-diagonals within the band of A ($kl \geq 0$).
ku	INTEGER. The number of super-diagonals within the band of A ($ku \geq 0$).
ab	REAL for sdbtrf DOUBLE PRECISION for ddbtrf COMPLEX for cdbtrf COMPLEX*16 for zdbtrf. Array, DIMENSION ($ldab, n$). The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl of the array need not be set. The j-th column of A is stored in the j-th column of the array ab as follows: $ab(kl+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$.

ldab INTEGER. The leading dimension of the array *ab*.
 $(ldab \geq 2kl + ku + 1)$

Output Parameters

ab On exit, details of the factorization: *u* is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the *Application Notes* below for further details.

info INTEGER.
 = 0: successful exit
 < 0: if *info* = - *i*, the *i*-th argument had an illegal value,
 > 0: if *info* = + *i*, *u*(*i*,*i*) is 0. The factorization has been completed, but the factor *u* is exactly singular. Division by 0 will occur if you use the factor *u* for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

on entry	on exit
$\begin{bmatrix} * & a12 & a23 & a34 & a45 & a56 \\ a11 & a22 & a33 & a44 & a55 & a66 \\ a21 & a32 & a43 & a54 & a65 & * \\ a31 & a42 & a53 & a64 & * & * \end{bmatrix}$	$\begin{bmatrix} * & u12 & u23 & u34 & u45 & u56 \\ u11 & u22 & u33 & u44 & u55 & u66 \\ m21 & m32 & m43 & m54 & m65 & * \\ m31 & m42 & m53 & m64 & * & * \end{bmatrix}$

The routine does not use array elements marked *.

?dtttrf

Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdttrf(n, dl, d, du, info)
call ddttrf(n, dl, d, du, info)
call cdttrf(n, dl, d, du, info)
call zdttrf(n, dl, d, du, info)
```

Description

This routine computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L^*U$, where L is a product of unit lower bidiagonal matrices and U is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

n INTEGER. The order of the matrix A ($n \geq 0$).

dl, d, du REAL for sdttrf
DOUBLE PRECISION for ddttrf
COMPLEX for cdttrf
COMPLEX*16 for zdttrf.
Arrays containing elements of A .
The array dl of DIMENSION $(n - 1)$ contains the sub-diagonal elements of A .
The array d of DIMENSION n contains the diagonal elements of A .
The array du of DIMENSION $(n - 1)$ contains the super-diagonal elements of A .

Output Parameters

dl Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .

<i>d</i>	Overwritten by the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i> .
<i>du</i>	Overwritten by the <i>(n-1)</i> elements of the first super-diagonal of <i>U</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value, > 0: if <i>info</i> = <i>i</i> , <i>u(i,i)</i> is exactly 0. The factorization has been completed, but the factor <i>U</i> is exactly singular. Division by 0 will occur if you use the factor <i>U</i> for solving a system of linear equations.

?dttrsv

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

Syntax

```
call sdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call ddttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call cdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call zdttrsv(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
```

Description

This routine solves one of the following systems of linear equations:

$$L * X = B, L^T * X = B, \text{ or } L^H * X = B,$$

$$U * X = B, U^T * X = B, \text{ or } U^H * X = B$$

with factors of the tridiagonal matrix *A* from the *LU* factorization computed by [?dttrf](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether to solve with <i>L</i> or <i>U</i> .
<i>trans</i>	CHARACTER. Must be 'N' or 'T' or 'C'.

Indicates the form of the equations:

If $trans = 'N'$, then $A^*X=B$ is solved for X (no transpose).

If $trans = 'T'$, then $A^T * X = B$ is solved for X (transpose).

If $trans = 'C'$, then $A^H * X = B$ is solved for X (conjugate transpose).

n INTEGER. The order of the matrix A ($n \geq 0$).

$nrhs$ INTEGER. The number of right-hand sides, that is, the number of columns in the matrix B ($nrhs \geq 0$).

dl, d, du, b REAL for sdttrsv
DOUBLE PRECISION for ddttrsv
COMPLEX for cdttrsv
COMPLEX*16 for zdttrsv.
Arrays of DIMENSIONS: $dl(n-1)$, $d(n)$, $du(n-1)$, $b(ldb, nrhs)$.
The array dl contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
The array d contains n diagonal elements of the upper triangular matrix U from the LU factorization of A .
The array du contains the $(n-1)$ elements of the first super-diagonal of U .
On entry, the array b contains the right-hand side matrix B .

ldb INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix X .

$info$ INTEGER. If $info=0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

?pttrsv

Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $L^*D^*L^H$ factorization computed by ?pttrf.

Syntax

```
call spttrsv(trans, n, nrhs, d, e, b, ldb, info)
call dpttrsv(trans, n, nrhs, d, e, b, ldb, info)
call cpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
call zpttrsv(uplo, trans, n, nrhs, d, e, b, ldb, info)
```

Description

This routine solves one of the triangular systems:

$L^T * X = B$, or $L * X = B$ for real flavors,

or

$L * X = B$, or $L^H * X = B$,

$U * X = B$, or $U^H * X = B$ for complex flavors,

where L (or U for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix A such that

$A = L^*D^*L^H$ (computed by [spttrf/dpttrf](#))

or

$A = U^H * D * U$ or $A = L^*D^*L^H$ (computed by [cpttrf/zpttrf](#)).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization: If <i>uplo</i> = 'U', e is the superdiagonal of U , and $A = U^H * D * U$ or $A = L^*D^*L^H$; if <i>uplo</i> = 'L', e is the subdiagonal of L , and $A = L^*D^*L^H$. The two forms are equivalent, if A is real.

<i>trans</i>	CHARACTER. Specifies the form of the system of equations: for real flavors: if <i>trans</i> = 'N': $L^*X = B$ (no transpose) if <i>trans</i> = 'T': $L^T * X = B$ (transpose) for complex flavors: if <i>trans</i> = 'N': $U^*X = B$ or $L^*X = B$ (no transpose) if <i>trans</i> = 'C': $U^H * X = B$ or $L^H * X = B$ (conjugate transpose).
<i>n</i>	INTEGER. The order of the tridiagonal matrix <i>A</i> . $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right hand sides, that is, the number of columns of the matrix <i>B</i> . $nrhs \geq 0$.
<i>d</i>	REAL array, DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> from the factorization computed by ?pttrf .
<i>e</i>	COMPLEX array, DIMENSION (<i>n</i> -1). The (<i>n</i> -1) off-diagonal elements of the unit bidiagonal factor <i>U</i> or <i>L</i> from the factorization computed by ?pttrf . See <i>uplo</i> .
<i>b</i>	COMPLEX array, DIMENSION (<i>ldb</i> , <i>nrhs</i>). On entry, the right hand side matrix <i>B</i> .
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> . $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	On exit, the solution matrix <i>x</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

```
call ssteqr2(compz, n, d, e, z, ldz, nr, work, info)
call dsteqr2(compz, n, d, e, z, ldz, nr, work, info)
```

Description

This routine is a modified version of LAPACK routine [?steqr](#). The routine [?steqr2](#) computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. [?steqr2](#) is modified from [?steqr](#) to allow each ScaLAPACK process running [?steqr2](#) to perform updates on a distributed matrix Q . Proper usage of [?steqr2](#) can be gleaned from examination of ScaLAPACK routine [p?syev](#).

Input Parameters

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T . z must be initialized to the identity matrix by p?laset or ?laset prior to entering this subroutine.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: d contains the diagonal elements of T . The dimension of d must be at least $\max(1, n)$. e contains the $(n-1)$ subdiagonal elements of T . The dimension of e must be at least $\max(1, n-1)$. $work$ is a workspace array. The dimension of $work$ is $\max(1, 2*n-2)$. If <i>compz</i> = 'N', then $work$ is not referenced.
<i>z</i>	(local) REAL for ssteqr2 DOUBLE PRECISION for dsteqr2

Array, global DIMENSION (n, n), local DIMENSION (ldz, nr).
 If *compz* = 'V', then *z* contains the orthogonal matrix used
 in the reduction to tridiagonal form.

ldz INTEGER. The leading dimension of the array *z*. Constraints:
 $ldz \geq 1$,
 $ldz \geq \max(1, n)$, if eigenvectors are desired.

nr INTEGER. $nr = \max(1, \text{numroc}(n, nb, myprow, 0, nprocs))$.
 If *compz* = 'N', then *nr* is not referenced.

Output Parameters

d REAL array, DIMENSION (n), for *ssteqr2*.
 DOUBLE PRECISION array, DIMENSION (n), for *dsteqr2*.
 On exit, the eigenvalues in ascending order, if *info* = 0.
 See also *info*.

e REAL array, DIMENSION ($n-1$), for *ssteqr2*.
 DOUBLE PRECISION array, DIMENSION ($n-1$), for *dsteqr2*.
 On exit, *e* has been destroyed.

z (local)
 REAL for *ssteqr2*
 DOUBLE PRECISION for *dsteqr2*
 Array, global DIMENSION (n, n), local DIMENSION (ldz, nr).
 On exit, if *info* = 0, then,
 if *compz* = 'V', *z* contains the orthonormal eigenvectors
 of the original symmetric matrix, and if *compz* = 'I', *z*
 contains the orthonormal eigenvectors of the symmetric
 tridiagonal matrix. If *compz* = 'N', then *z* is not referenced.

info INTEGER.
info = 0, the exit is successful.
info < 0: if *info* = $-i$, the i -th had an illegal value.
info > 0: the algorithm has failed to find all the
 eigenvalues in a total of $30n$ iterations;
 if *info* = i , then i elements of *e* have not converged to
 zero; on exit, *d* and *e* contain the elements of a symmetric
 tridiagonal matrix, which is orthogonally similar to the
 original matrix.

Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

Table 7-2 ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
<code>p?labad</code>	<code>s, d</code>	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
<code>p?lachieee</code>	<code>s, d</code>	Performs a simple check for the features of the IEEE standard. (C interface function).
<code>p?lamch</code>	<code>s, d</code>	Determines machine parameters for floating-point arithmetic.
<code>p?lasnbt</code>	<code>s, d</code>	Computes the position of the sign bit of a floating-point number. (C interface function).
<code>pxerbla</code>		Error handling routine called by ScaLAPACK routines.

`p?labad`

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call pslabad(ictxt, small, large)
```

```
call pdlabad(ictxt, small, large)
```

Description

This routine takes as input the values computed by `p?lamch` for underflow and overflow, and returns the square root of each of these values if the log of `large` is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `p?lamch`. This subroutine is needed because `p?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this routine performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

<i>ictxt</i>	(global) INTEGER. The BLACS context handle in which the computation takes place.
<i>small</i>	(local). REAL PRECISION for pslabad. DOUBLE PRECISION for pdlabad. On entry, the underflow threshold as computed by p?lamch.
<i>large</i>	(local). REAL PRECISION for pslabad. DOUBLE PRECISION for pdlabad. On entry, the overflow threshold as computed by p?lamch.

Output Parameters

<i>small</i>	(local). On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	(local). On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

p?lachkieee

Performs a simple check for the features of the IEEE standard. (C interface function).

Syntax

```
void pslachkieee(int *isieee, float *rmax, float *rmin);
void pdlachkieee(int *isieee, float *rmax, float *rmin);
```

Description

This routine performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, p?lachkieee may not return.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

<i>rmax</i>	(local). REAL for pslach IEEE DOUBLE PRECISION for pdlach IEEE The overflow threshold (= ?lamch ('O')).
<i>rmin</i>	(local). REAL for pslach IEEE DOUBLE PRECISION for pdlach IEEE The underflow threshold (= ?lamch ('U')).

Output Parameters

<i>isieee</i>	(local). INTEGER. On exit, <i>isieee</i> = 1 implies that all the features of the IEEE standard that we rely on are implemented. On exit, <i>isieee</i> = 0 implies that some the features of the IEEE standard that we rely on are missing.

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
val = pslamch(ictxt, cmach)
val = pdlamch(ictxt, cmach)
```

Description

This routine determines single precision machine parameters.

Input Parameters

ictxt (global). INTEGER. The BLACS context handle in which the computation takes place.

cmach (global) CHARACTER*1.
Specifies the value to be returned by p?lamch:

- = 'E' or 'e', p?lamch := eps
- = 'S' or 's', p?lamch := sfmin
- = 'B' or 'b', p?lamch := base
- = 'P' or 'p', p?lamch := eps*base
- = 'N' or 'n', p?lamch := t
- = 'R' or 'r', p?lamch := rnd
- = 'M' or 'm', p?lamch := emin
- = 'U' or 'u', p?lamch := rmin
- = 'L' or 'l', p?lamch := emax
- = 'O' or 'o', p?lamch := rmax,

where

- eps = relative machine precision
- sfmin = safe minimum, such that 1/sfmin does not overflow
- base = base of the machine
- prec = eps*base
- t = number of (base) digits in the mantissa
- rnd = 1.0 when rounding occurs in addition, 0.0 otherwise
- emin = minimum exponent before (gradual) underflow
- rmin = underflow threshold - $\text{base}^{(\text{emin}-1)}$
- emax = largest exponent before overflow
- rmax = overflow threshold - $(\text{base}^{\text{emax}}) * (1-\text{eps})$

Output Parameters

val Value returned by the routine.

pslasnbt

Computes the position of the sign bit of a floating-point number. (C interface function).

Syntax

```
void pslasnbt(int *ieflag);
```

```
void pdlasnbt(int *ieflag);
```

Description

This routine finds the position of the signbit of a single/double precision floating point number. This routine assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

Output Parameters

ieflag

INTEGER.

This flag indicates the position of the signbit of any single/double precision floating point number.

ieflag = 0, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.

ieflag = 1 indicates that the signbit is the 32-nd bit for a single precision routine.

In the case of a double precision routine:

ieflag = 1 indicates that the signbit is the 32-nd bit (Big Endian).

ieflag = 2 indicates that the signbit is the 64-th bit (Little Endian).

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
call pxerbla(ictxt, sname, info)
```

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called by a *ScaLAPACK* routine if an input parameter has an invalid value. A message is printed. Program execution is not terminated. For the ScaLAPACK driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and it is left to the user to determine how the program should proceed. However, in the specialized low-level ScaLAPACK routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *info* on return from a ScaLAPACK routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Input Parameters

<i>ictxt</i>	(global) INTEGER The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) CHARACTER*6 The name of the routine which called <code>pxerbla</code> .
<i>info</i>	(global) INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or non-symmetric, positive definite, indefinite or Hermitian sparse linear system of equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the [Appendix A "Linear Solvers Basics"](#) [Appendix "Linear Solvers Basics"](#) . If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes the direct sparse solver [PARDISO*](#) and the alternative interface for the direct sparse solver referred to here as [DSS interface](#); [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI); and [two preconditioners](#) based on the incomplete LU factorization technique.

PARDISO* - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the PARDISO* solver. The interface is Fortran, but can be called from C programs by observing Fortran parameter passing and naming conventions used by the supported compilers and operating systems. A discussion of the algorithms used in the PARDISO* software and more information on the solver can be found at <http://www.pardiso-project.org>.

The current implementation of the PARDISO* solver additionally supports the out-of-core (OOC) version.

The PARDISO* package is a high-performance, robust, memory efficient and easy to use software for solving large sparse symmetric and unsymmetric linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [[Schenk00-2](#)]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [[Schenk00](#), [Schenk01](#), [Schenk02](#), [Schenk03](#)]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture and a speedup of up to seven using eight processors has been observed.

The PARDISO* solver supports a wide range of sparse matrix types (see [Figure 8-1](#) below) and computes the solution of real or complex, symmetric, structurally symmetric or unsymmetric, positive definite, indefinite or Hermitian sparse linear system of equations on shared-memory multiprocessing architectures.

Figure 8-1 Sparse Matrices That Can Be Solved with the PARDISO* Solver

You can find a code example that uses the PARDISO interface routine to solve systems of linear equations in [PARDISO Code Examples](#) section in the [Appendix C](#).

pardiso

Calculates the solution of a set of sparse linear equations with multiple right-hand sides.

Syntax

Fortran:

```
call pardiso (pt, maxfct, mnum, type, phase, n, a, ia, ja, perm, nrhs, iparm,
msglvl, b, x, error)
```

C:

```
pardiso (pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs,
iparm, &msglvl, b, x, &error);
```

(An underscore may or may not be required after “pardiso” depending on the OS and compiler conventions for that OS).

Interface:

```
SUBROUTINE pardiso (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs,
iparm, msglvl, b, x, error)
```

```
INTEGER *4 pt (64)
```

```
INTEGER *4 maxfct, mnum, mtype, phase, n, nrhs, error, ia(*), ja(*), perm(*),
iparm(*)
```

```
REAL *8 a(*), b(n,nrhs), x(n,nrhs)
```

Note that the above interface is given for the 32-bit architectures. For 64-bit architectures, the argument `pt(64)` must be defined as `INTEGER*8` type.

Description

PARDISO calculates the solution of a set of sparse linear equations

$$A \cdot X = B$$

with multiple right-hand sides, using a parallel LU , LDL or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ matrices. PARDISO performs the following analysis steps depending on the structure of the input matrix A .

Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite matrices, and an approximation of x is found by forward and backward substitution and iterative refinements.

The coefficient matrix is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block. One or two passes of iterative refinements may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinements is effective for highly indefinite symmetric systems. Furthermore the

accuracy of this method is for a large set of matrices from different applications areas as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another possibility to improve the pivoting accuracy is to use symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and iterative refinements.

Unsymmetric Matrices: The solver first computes a non-symmetric permutation P_{MPS} and scaling matrices D_x and D_c with the aim to place large entries on the diagonal that enhances reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)_T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_xAD_cP$$

with supernode pivoting matrices Q and R . When the factorization algorithm reaches a point where it cannot factorize the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of $\alpha = \epsilon * ||A2||_{inf}$, where ϵ is the machine precision, $A2 = P * P_{MPS} * D_x * A * D_c * P$, and $||A2||_{inf}$ is the infinity norm of the scaled and permuted matrix A . Any tiny pivots encountered during elimination are set to the sign $(l_{II}) * \epsilon * ||A2||_{inf}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Direct-Iterative Preconditioning for Unsymmetric Linear Systems. The solver also allows for a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most of applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but the same identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed

only once and the numerical factorizations are the important time-consuming steps during the simulation. PARDISO uses a numerical factorization $A = LU$ for the first system and applies the factors L and U for the next steps in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to unsymmetric matrices in PARDISO and the user can select the method using only one input parameter. For further details see the parameter description (*iparm(4)*, *iparm(20)*).

The sparse data storage in PARDISO follows the scheme described in [Sparse Matrix Storage Format](#) section with *ja* standing for *columns*, *ia* for *rowIndex*, and *a* for *values*. The algorithms in PARDISO require column indices *ja* to be increasingly ordered per row and the presence of the diagonal element per row for any symmetric or structurally symmetric matrix. The unsymmetric matrices need no diagonal elements in the PARDISO solver.

PARDISO performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

When an input data structure is not accessed in a call, a `NULL` pointer or any valid address can be passed as a place holder for that argument.

Input Parameters

pt `INTEGER*4` for 32 -bit operating systems;
 `INTEGER*8` for 64 -bit operating systems
 Array, `DIMENSION (64)`
 On entry, solver internal data address pointer. These addresses are passed to the solver and all related internal memory management is organized through this pointer

NOTE. *pt* is an integer array with 64 entries. It is very important that the pointer is initialized with zero at the first call of PARDISO. After that first call you should never modify the pointer, as a serious memory leak can occur. The integer length should be 4-byte on 32-bit operating systems and 8-byte on 64-bit operating systems.

maxfct

INTEGER

Maximal number of factors with identical nonzero sparsity structure that the user would like to keep at the same time in memory. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data management of the solver. In most of the applications this value is equal to 1.

PARDISO can process several matrices with identical matrix sparsity pattern and store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

mnum

INTEGER

Actual matrix for the solution phase. With this scalar you can define the matrix that you would like to factorize. The value must be: $1 \leq mnum \leq maxfct$.

In most applications this value is equal to 1.

mtype

INTEGER

This scalar value defines the matrix type. The PARDISO solver supports the following matrices:

- = 1 real and structurally symmetric matrix
- = 2 real and symmetric positive definite matrix
- = -2 real and symmetric indefinite matrix
- = 3 complex and structurally symmetric matrix
- = 4 complex and Hermitian positive definite matrix
- = -4 complex and Hermitian indefinite matrix
- = 6 complex and symmetric matrix
- = 11 real and unsymmetric matrix
- = 13 complex and unsymmetric matrix

This parameter influences the pivoting method.

phase

INTEGER

Controls the execution of the solver. It is a two-digit integer ij ($10I + j$, $1 \leq I \leq 3$, $I < j \leq 3$ for normal execution modes). The I digit indicates the starting phase of execution, and j indicates the ending phase. PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including iterative refinements
- Termination and Memory Release Phase ($phase \leq 0$)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
0	Release internal memory for L and U matrix number <i>mnum</i>
-1	Release all internal memory for all matrices

<i>n</i>	INTEGER Number of equations in the sparse linear systems of equations $A * X = B$. Constraint: $n > 0$.
<i>a</i>	REAL/COMPLEX Array. Contains the nonzero values of the coefficient matrix A corresponding to the indices in <i>ja</i> . The size of <i>a</i> is the same as that of <i>ja</i> and the coefficient matrix can be either

real or complex. The matrix must be stored in compressed sparse row format with increasing values of ja for each row. Refer to *values* array description in [Sparse Matrix Storage Format](#) for more details.

NOTE. The nonzeros of each row of the matrix A must be stored in increasing order. For symmetric or structural symmetric matrices, it is also important that the diagonal elements are available and stored in the matrix. If the matrix is symmetric, the array a is only accessed in the factorization phase, in the triangular solution and iterative refinement phase. Unsymmetric matrices are accessed in all phases of the solution process.

ia

INTEGER

Array, dimension $(n+1)$. For $I \leq n$, $ia(I)$ points to the first column index of row I in the array ja in compressed sparse row format. That is, $ia(I)$ gives the index of the element in array a that contains the first non-zero element from row I of A . The last element $ia(n+1)$ is taken to be equal to the number of non-zeros in A , plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Format](#) for more details. The array ia is also accessed in all phases of the solution process. Note that the row and columns numbers start from 1.

ja

INTEGER

Array. $ja(*)$ contains column indices of the sparse matrix A stored in compressed sparse row format. The indices in each row must be sorted in increasing order. The array ja is also accessed in all phases of the solution process. For symmetric and structurally symmetric matrices it is assumed that zero diagonal elements are also stored in the list of nonzeros in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Sparse Matrix Storage Format](#).

<i>perm</i>	INTEGER Array, dimension (n). Holds the permutation vector of size n. The array <i>perm</i> is defined as follows. Let A be the original matrix and $B = P^*A^*P^T$ be the permuted matrix. Row (column) i of A is the $perm(i)$ row (column) of B. The numbering of the array must start with 1 and must describe a permutation. On entry, you can apply your own fill-in reducing ordering to the solver. The permutation vector <i>perm</i> is only accessed if $iparm(5) = 1$.
<i>nrhs</i>	INTEGER Number of right-hand sides that need to be solved for.
<i>iparm</i>	INTEGER Array, dimension (64). This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver. If $iparm(1) = 0$, PARDISO fills $iparm(1)$, and $iparm(4)$ through $iparm(64)$ with default values and uses them. Note that there is no default value for $iparm(3)$ and the user should supply this value, whether $iparm(1)$ is 0 or 1. Individual components of the <i>iparm</i> array are described below (some of them are described in the Output Parameters section). <i>iparm(1)</i> - use default values. If $iparm(1) = 0$, $iparm(2)$ and $iparm(4)$ through $iparm(64)$ are filled with default values, otherwise the user has to supply all values in <i>iparm</i> from $iparm(2)$ to $iparm(64)$. <i>iparm(2)</i> - fill-in reducing ordering. $iparm(2)$ controls the fill-in reducing ordering for the input matrix. If $iparm(2)$ is 0, the minimum degree algorithm is applied [Li99], if $iparm(2)$ is 2, the solver uses the nested dissection algorithm from the METIS package [Karypis98]. The default value of $iparm(2)$ is 2. <i>iparm(3)</i> - number of processors. $iparm(3)$ must contain the number of processors that are available for the parallel execution. The number must be equal to the MKL environment variable <code>MKL_NUM_THREADS</code>.

CAUTION. User is supposed to control the parallel execution of the solver by explicitly setting `MKL_NUM_THREADS`. If less processors are available than specified, the execution may slow down instead of speeding up.

There is no default value for `iparm(3)`.

`iparm(4)` - preconditioned CGS.

This parameter controls preconditioned CGS [Sonn89] for unsymmetric or structural symmetric matrices and Conjugate-Gradients for symmetric matrices. `iparm(4)` has the form

`iparm(4) = 10 * L + K`

The K and L values have the meanings as follow.

Value of κ Description

0	The factorization is always computed as required by <code>phase</code> .
1	CGS iteration replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.
2	CG iteration for symmetric matrices replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.

Value L :

The value L controls the stopping criterion of the Krylow-Subspace iteration:

$\text{eps}_{\text{CGS}} = 10^{-L}$ is used in the stopping criterion

$\|dx_I\| / \|dx_1\| < \text{eps}_{\text{CGS}}$

with $||dx_I|| = ||\text{inv}(L*U)*r_I||$ and r_I is the residuum at iteration I of the preconditioned Krylow-Subspace iteration.

Strategy: A maximum number of 150 iterations is fixed by expecting that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residuum excursions are checked and can terminate the iteration process. If $phase = 23$, then the factorization for a given A is automatically recomputed in these cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using $phase = 33$ results in an error message ($error = 4$) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from $iparm(20)$.

The default is $iparm(4) = 0$, and other values are only recommended for an advanced user. $iparm(4)$ must be greater or equal to zero.

Examples:

$iparm(4)$	Description
31	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for unsymmetric matrices
61	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for unsymmetric matrices
62	LU -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric matrices

$iparm(5)$ - user permutation.

This parameter controls whether the user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms.

This option may be useful for testing reordering algorithms or adapting the code to special applications problems (for instance, to move zero diagonal elements to the end $P^*A^*P^T$). For definition of the permutation, see description of the *perm* parameter.

The default value of *iparm*(5) is 0.

iparm(6) - write solution on *x*.

If *iparm*(6) is 0 (which is the default), then the array *x* contains the solution and the value of *b* is not changed. If *iparm*(6) is 1, then the solver will store the solution on the right hand side *b*.

Note that the array *x* is always used. The default value of *iparm*(6) is 0.

iparm(8)

On entry to the solve and iterative refinement step, *iparm*(8) should be set to the maximum number of iterative refinement steps that the solver will perform. The solver will not perform more than the absolute value of *iparm*(8) steps of iterative refinement and will stop the process if a satisfactory level of accuracy of the solution in terms of backward error has been achieved.

Note that if *iparm*(8) < 0, the accumulation of the residuum is using extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of *iparm*(8)=0) and the iteration number executed is reported on *iparm*(7).

The solver will automatically perform two steps of iterative refinements when perturbed pivots have been obtained during the numerical factorization and *iparm*(8) was equal to zero.

The number of performed iterative refinement steps is reported on *iparm*(8).

The default value for *iparm*(8) is 0.

iparm(9)

This parameter is reserved for future use. Its value must be set to 0.

iparm(10) - pivoting perturbation.

This parameter instructs PARDISO how to handle small pivots or zero pivots for unsymmetric matrices ($mtype = 11$ or $mtype = 13$) and symmetric matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factorize the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].

The magnitude of the potential pivot is tested against a constant threshold of

$$\alpha = \text{eps} * ||A2||_{\text{inf}},$$

where $\text{eps} = 10^{(-iparm(10))}$, $A2 = P * P_{MPS} * D_r * A * D_c * P$, and $||A2||_{\text{inf}}$ is the infinity norm of the scaled and permuted matrix A . Any tiny pivots encountered during elimination are set to the sign $(l_{II}) * \text{eps} * ||A2||_{\text{inf}}$ - this trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-iparm(10))}$.

The default value of $iparm(10)$ is 13 and therefore $\text{eps} = 1.0\text{E-}13$ for unsymmetric matrices ($mtype = 11$ or $mtype = 13$).

The default value of $iparm(10)$ is 8, and therefore $\text{eps} = 1.0\text{E-}8$ for symmetric indefinite matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$).

$iparm(11)$ - scaling vectors.

PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied only to unsymmetric matrices ($mtype = 11$ or $mtype = 13$). The scaling can also be used for symmetric indefinite matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$) when the symmetric weighted matchings are applied ($iparm(13) = 1$).

Use $iparm(11) = 1$ (scaling) and $iparm(13) = 1$ (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point

problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of scaling and symmetric weighted matching.

The default value of *iparm*(11) is 1 for unsymmetric matrices (*mtype* =11 or *mtype* =13). The default value of *iparm*(11) is 0 for symmetric indefinite matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6).

iparm(12)

This parameter is reserved for future use. Its value must be set to 0.

iparm(13) - improved accuracy using (non-)symmetric weighted matchings.

PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to our factorization methods and can be seen as a complement to the alternative idea of using more complete pivoting techniques during the numerical factorization.

It is recommended to use *iparm*(11) =1 (scalings) and *iparm*(13) =1 (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. It is also very important to note that in the analysis phase (*phase* =11) you must provide the numerical values of the matrix *A* in the case of scalings and symmetric weighted matchings.

The default value of *iparm*(13) is 1 for unsymmetric matrices (*mtype* =11 or *mtype* =13). The default value of *iparm*(13) is 0 for symmetric matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6).

iparm(18)

The solver will report the numbers of nonzeros on the factors if *iparm*(18) < 0 on entry.

The default value of *iparm*(18) is -1.

iparm(19) - MFlops of factorization.

If *iparm*(19) < 0 on entry, the solver will report MFlop (1.0E6) that are necessary to factor the matrix *A*. This will increase the reordering time.

The default value of *iparm*(19) is 0.

iparm(21) - pivoting for symmetric indefinite matrices

iparm(21) controls the pivoting method for sparse symmetric indefinite matrices. If *iparm*(21) is 0, then 1x1 diagonal pivoting is used. If *iparm*(21) is 1, then 1x1 and 2x2 Bunch and Kaufman pivoting will be used in the factorization process. If *iparm*(21) is 2, a very robust preprocessing method based on symmetric weighted matchings and 1x1 and 2x2 Bunch and Kaufman pivoting will be used in the factorization process. The default value of *iparm*(21) is 1. Bunch and Kaufman pivoting is available for matrices: *mtype*=-2, *mtype*=-4, or *mtype*=6.

iparm(60)

iparm(60) controls what version of PARDISO - out-of-core (OOC) version or in-core version - is used. The OOC PARDISO can solve very large problems by holding the matrix factors in files on the disk. Because of that the amount of main memory required by OOC PARDISO is significantly reduced.

WARNING. The current OOC version does not use threading, thus both the parameter *iparm*(3) and the variable `MKL_NUM_THREADS` must be set to 1 when *iparm*(60) is equal to 1 or 2.

If *iparm*(60) is set to 0, then the in-core PARDISO is used. If *iparm*(60) is set to 2 - the OOC PARDISO is used. If *iparm*(60) is set to 1 - the in-core PARDISO is used if the total memory (in MBytes) needed for storing the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` (its default value is 2000), and OOC PARDISO is used otherwise. The default value of *iparm*(60) is 0.

Note that if *iparm*(60) is equal to 1 or 2, and the total peak memory needed for strong local arrays is less than `MKL_PARDISO_OOC_MAX_CORE_SIZE`, the program stops with error -9. In this case, increase of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is recommended.

OOO parameters can be set in the configuration file. You can set the path to this file and its name via environmental variable `MKL_PARDISO_OOC_CFG_PATH` and

`MKL_PARDISO_OOC_CFG_FILE_NAME`.

Path and name are as follows:

`<MKL_PARDISO_OOC_CFG_PATH >/<`

`MKL_PARDISO_OOC_CFG_FILE_NAME>` for Linux* OS, and

`<MKL_PARDISO_OOC_CFG_PATH >\<`

`MKL_PARDISO_OOC_CFG_FILE_NAME>` for Windows* OS.

By default, the name of the file is `pardiso_ooc.cfg` and it is placed to the current directory.

All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable `MKL_PARDISO_OOC_KEEP_FILE`. If it is set to 1 (default value) - all files are deleted, if it is set to 0 - all files are stored.

By default, the OOO PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named `ooc_temp` with different extensions. These default values can be changed by using the environmental variable `MKL_PARDISO_OOC_PATH`.

To set the environmental variables

`MKL_PARDISO_OOC_MAX_CORE_SIZE`,

`MKL_PARDISO_OOC_KEEP_FILE`, and

`MKL_PARDISO_OOC_PATH`, the configuration file should be created with the following lines:

`MKL_PARDISO_OOC_PATH = <path>\ooc_file`

`MKL_PARDISO_OOC_MAX_CORE_SIZE = N`

`MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)`

where `<path>` - the directory for storing data, `ooc_file` - file name without extension, `N` - memory size in MBytes, it is not recommended to set this value greater than the size of the available RAM (default value - 2000 MBytes).

Alternatively the environment variables can be set via command line:

`export MKL_PARDISO_OOC_PATH = <path>/ooc_file`

`export MKL_PARDISO_OOC_MAX_CORE_SIZE = N`

`export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)`

for Linux* OS, and

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
for Windows* OS.
```

NOTE. The values specified in a command line have higher priorities - it means that if variable is changed in the configuration file and in the command line, OOC PARDISO uses only value defined in the command line. Setting OOC parameters via command line is recommended.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then PARDISO generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

b

REAL/COMPLEX

Array, dimension (*n*, *nrhs*). On entry, contains the right hand side vector/matrix *B*. Note that *b* is only accessed in the solution phase.

Output Parameters

pt

This parameter contains internal address pointers.

iparm

On output, some *iparm* values will report useful information, for example, numbers of nonzeros in the factors, and so on.
iparm(7) - number of performed iterative refinement steps. The number of iterative refinement steps that are actually performed during the solve step.
iparm(14) - number of perturbed pivots.
 After factorization, *iparm*(14) contains the number of perturbed pivots during the elimination process for *mtype* = 11, *mtype* = 13, *mtype* = -2, *mtype* = -4, or *mtype* = -6.
iparm(15) - peak memory symbolic factorization.

The parameter *iparm*(15) provides the user with the total peak memory in KBytes that the solver needed during the analysis and symbolic factorization phase. This value is only computed in phase 1.

iparm(16) - permanent memory symbolic factorization.

The parameter *iparm*(16) provides the user with the permanent memory in KBytes that the solver needed from the analysis and symbolic factorization phase in the factorization and solve phases. This value is only computed in phase 1.

iparm(17) - memory numerical factorization and solution.

The parameter *iparm*(17) provides the user with the total double precision memory consumption (KBytes) of the solver for the factorization and solve phases. This value is only computed in phase 2.

Note that the total peak memory solver consumption is

$\max(iparm(15), iparm(16) + iparm(17))$

iparm(18) - number of nonzeros in factors.

The solver will report the numbers of nonzeros on the factors if *iparm*(18) < 0 on entry.

iparm(19) - MFlops of factorization.

Number of operations in MFlop (1.0E6 operations) that are necessary to factor the matrix *A* are returned to the user if *iparm*(19) < 0 on entry.

iparm(20) - CG/CGS diagnostics.

The value is used to give CG/CGS diagnostics (for example, the number of iterations and cause of failure):

If *iparm*(20) > 0, CGS succeeded, and the number of iterations executed are reported in *iparm*(20).

If *iparm*(20) < 0, iterations executed, but CG/CGS failed.

The error report details in *iparm*(20) are of the form:

iparm(20) = - *it_cgs**10 - *cgs_error*.

If *phase* is 23, then the factors *L*, *U* are recomputed for the matrix *A* and the error flag *error* is zero in case of a successful factorization. If *phase* is 33, then *error* = -4 signals the failure.

Description of *cgs_error* is given in the table below:

cgs_error Description

1	- fluctuations of the residuum are too large
2	- $\ dx_{\max_it_cgs}/2\ $ too large (slow convergence)
3	- stopping criterion not reached at $\max\_it\_cgs$
4	- perturbed pivots caused iterative refinement
5	- factorization is too fast for this matrix. It is better to use the factorization method with $iparm(4)=0$

iparm(22) - inertia: number of positive eigenvalues.

The parameter *iparm(22)* reports the number of positive eigenvalues for symmetric indefinite matrices.

iparm(23) - inertia: number of negative eigenvalues.

The parameter *iparm(23)* reports the number of negative eigenvalues for symmetric indefinite matrices.

iparm(24) to *iparm(59)*

These parameters are reserved for future use. Their values must be set to 0.

iparm(61) - the total peak memory in MBytes that the solver used during the analysis and symbolic factorization phases if the in-core PARDISO is used. *iparm(61)* is similar to *iparm(15)*, but *iparm(15)* returns the value of the total peak memory if the OOC PARDISO is used.

iparm(62) - the total double precision memory consumption in MBytes that the solver used during the analysis and symbolic factorization phase in the factorization and solver phases if the in-core PARDISO is used. *iparm(62)* is similar to *iparm(16)*, but *iparm(16)* returns the value of the memory consumption if the OOC PARDISO is used.

iparm(63) - the total double precision memory consumption in MBytes that the solver used for factorization and solution phases if the in-core PARDISO is used. Value of *iparm(63)* is similar to *iparm(17)*, but *iparm(17)* returns the value of the memory consumption if the OOC PARDISO is used.

<i>b</i>	On output, the array is replaced with the solution if $iparm(6) = 1$.
<i>x</i>	REAL/COMPLEX Array, dimension $(n, nrhs)$. On output, contains solution if $iparm(6)=0$. Note that <i>x</i> is only accessed in the solution phase.
<i>error</i>	INTEGER The error indicator according to the below table:
error	Information
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	zero pivot, numerical factorization or iterative refinement problem
-5	unclassified (internal) error
-6	preordering failed (matrix types 11, 13 only)
-7	diagonal matrix problem
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	problems with opening OOC temporary files
-11	read/write problems with the OOC data file

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports an alternative to the PARDISO* interface for the direct sparse solver referred to here as DSS interface. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and exploits the general scheme described in [Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process and an auxiliary routine for passing character strings from Fortran routines to C routines.

The current implementation of the DSS interface additionally supports the out-of-core (OOC) version.

Table 8-1 lists the names of the routines and describes their general use.

Table 8-1 DSS Interface Routines

Routine	Description
<code>dss_create</code>	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
<code>dss_define_structure</code>	Informs the solver of the locations of the non-zero elements of the array.
<code>dss_reorder</code>	Based on the non-zero structure of the matrix, this routine computes a permutation vector to reduce fill-in during the factoring process.
<code>dss_factor_real,</code> <code>dss_factor_complex</code>	Computes the LU , LDT^T or LL^T factorization of a real or complex matrix.
<code>dss_solve_real, dss_solve_complex</code>	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
<code>dss_delete</code>	Deletes all data structures created during the solving process.
<code>dss_statistics</code>	Returns statistics about various phases of the solving process. Gathers the following statistics: time taken to do reordering, time taken to do factorization, problem solving duration, determinant of a matrix, inertia of a matrix, number of floating point operations taken during factorization, peak memory symbolic factorization, permanent memory symbolic factorization, and memory numerical factorization and solution. This routine can be invoked in any phase of the solving process after the "reorder" phase, but before the "delete" phase. Note that appropriate argument(s) must be supplied to this routine to match the phase in which it is invoked.
<code>mkl_cvt_to_null_terminated_str</code>	Passes character strings from Fortran routines to C routines.

To find a single solution vector for a single system of equations with a single right hand side, the Intel MKL DSS interface routines are invoked in the order in which they are listed in [Table 8-1](#) , with the exception of `dss_statistics`, which is invoked as described in the table.

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is necessary to invoke the Intel MKL sparse routines in an order other than listed in the table. The DSS interface provides such option. The solving process is conceptually divided into six phases, as shown in [Figure 8-2](#) , that indicates the typical order(s) in which the DSS interface routines can be invoked.

Figure 8-2 Typical order for invoking DSS interface routines

See code examples that uses the DSS interface routines to solve systems of linear equations in [Direct Sparse Solver Examples](#) section in the appendix C.

DSS Interface Description

As noted in [Memory Allocation and Handles](#) section, each DSS routine reads or writes an opaque data object called a handle. It is declared as being of type `MKL_DSS_HANDLE` in this documentation. You can refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument.

All other types in this documentation refer to the common Fortran types, `INTEGER`, `REAL`, `COMPLEX`, `DOUBLE PRECISION`, and `DOUBLE COMPLEX`.

C and C++ programmers should refer to [Calling Direct Sparse Solver and Preconditioner Routines From C/C++](#) section for information on mapping Fortran types to C/C++ types.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the message and termination levels as described in [Table 8-2](#) . Additionally, the routines accept the option `MKL_DSS_DEFAULTS` that establishes the documented default options for each DSS routine.

Table 8-2 Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
<code>MKL_DSS_MSG_LVL_SUCCESS</code>	<code>MKL_DSS_TERM_LVL_SUCCESS</code>
<code>MKL_DSS_MSG_LVL_INFO</code>	<code>MKL_DSS_TERM_LVL_INFO</code>
<code>MKL_DSS_MSG_LVL_WARNING</code>	<code>MKL_DSS_TERM_LVL_WARNING</code>
<code>MKL_DSS_MSG_LVL_ERROR</code>	<code>MKL_DSS_TERM_LVL_ERROR</code>
<code>MKL_DSS_MSG_LVL_FATAL</code>	<code>MKL_DSS_TERM_LVL_FATAL</code>

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

Users can specify multiple options for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
CALL dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL DSS routines do not make copies of the user input arrays.

WARNING. The contents of these arrays cannot be modified after they are passed to one of the solver routines.

dss_create

Initializes the solver.

Syntax

```
dss_create(handle, opt)
```

Description

The routine `dss_create` initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of `handle` returned by the routine `dss_create`.

WARNING. Do not write the value of `handle` directly.

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR .
```

This parameter can contain additionally one of two possible values to launch the out-of-core version of DSS (OOC DSS): `MKL_DSS_OOC_VARIABLE` and `MKL_DSS_OOC_STRONG`.

`MKL_DSS_OOC_STRONG` - OOC DSS is used.

`MKL_DSS_OOC_VARIABLE` - OOC DSS uses the in-core kernels of PARDISO* if there is enough memory for storing work arrays associated with the matrix factors in the main memory. Specifically, if the memory needed for the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE`, then the OOC version of PARDISO* uses the in-core computations, otherwise it uses the OOC computations.

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of the main memory allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MBytes. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the [PARDISO Parameters](#) description above).

WARNING. Do not change the behavior of the OOC DSS after it is specified in the routine `dss_create`.

Input Parameters

opt INTEGER Options passing argument. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

handle Data object of the `MKL_DSS_HANDLE` type (see [Interface Description](#)).

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

dss_define_structure

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

```
dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Description

The routine `dss_define_structure` communicates the locations of the *nNonZeros* number of non-zero elements in a matrix of *nRows* by *nCols* size to the solver.

Note that currently the Intel MKL DSS software operates only on square matrices, so *nRows* must be equal to *nCols*.

To communicate the locations of non-zeros in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying one of the following values for the options argument *opt*:

- `MKL_DSS_SYMMETRIC_STRUCTURE`

- MKL_DSS_SYMMETRIC
- MKL_DSS_NON_SYMMETRIC

2. Provide the actual locations of the non-zeros by means of the arrays *rowIndex* and *columns* (see [Sparse Matrix Storage Format](#)).

Input Parameters

<i>opt</i>	INTEGER. Options passing argument. The default option for the matrix structure is MKL_DSS_SYMMETRIC.
<i>rowIndex</i>	INTEGER. Array of size $\min(nRows, nCols)+1$. Defines the location of non-zero entries in the matrix.
<i>nRows</i>	INTEGER. Number of rows in the matrix.
<i>nCols</i>	INTEGER. Number of columns in the matrix.
<i>columns</i>	INTEGER. Array of size <i>nNonZeros</i> . Defines the location of non-zero entries in the matrix.
<i>nNonZeros</i>	INTEGER. Number of non-zero elements in the matrix.

WARNING.

Pointers to the *rowIndex* and *columns* are stored in the handle. These arrays are used when the solver runs. Do not free or delete them before calling `dss_solve_real` or `dss_solver_complex`.

Output Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_COL_ERR

MKL_DSS_NOT_SQUARE
 MKL_DSS_TOO_FEW_VALUES
 MKL_DSS_TOO_MANY_VALUES

dss_reorder

Computes permutation vector that minimizes the fill-in during the factorization phase.

Syntax

`dss_reorder(handle, opt, perm)`

Description

If *opt* contains the option MKL_DSS_AUTO_ORDER, then the routine `dss_reorder` computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the *perm* array is never accessed.

If *opt* contains the option MKL_DSS_MY_ORDER, then the array *perm* is considered to be a permutation vector supplied by the user. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to [dss_define_structure](#).

Input Parameters

<i>opt</i>	INTEGER. Option passing argument. The default option for the permutation type is MKL_DSS_AUTO_ORDER.
<i>perm</i>	INTEGER. Array of length <i>nRows</i> . Contains a user-defined permutation vector (accessed only if <i>opt</i> contains MKL_DSS_MY_ORDER).

Output Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location.

Syntax

```
dss_factor_real(handle, opt, rValues)
```

```
dss_factor_complex(handle, opt, cValues)
```

Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to [dss_define_structure](#) and whose non-zero values are given in the array *rValues* or *cValues*. The arrays *rValues* and *cValues* are assumed to be of length *nNonZeros* as defined in a previous call to [dss_define_structure](#).

The *opt* argument should contain one of the following options:

- MKL_DSS_POSITIVE_DEFINITE,
- MKL_DSS_INDEFINITE,
- MKL_DSS_HERMITIAN_POSITIVE_DEFINITE,
- MKL_DSS_HERMITIAN_INDEFINITE ,

depending on whether the non-zero values in *rValues* and *cValues* describe a positive definite, indefinite, or Hermitian matrix.

Input Parameters

<i>handle</i>	Data object of the MKL_DSS_HANDLE type (see Interface Description).
<i>opt</i>	INTEGER Options passing argument. The default option for the matrix type is MKL_DSS_POSITIVE_DEFINITE.
<i>rValues</i>	DOUBLE PRECISION. Array of size <i>nNonZeros</i> . Contains real non-zero elements of the matrix.

cValues DOUBLE COMPLEX. Array of size *nNonZeros*. Contains complex non-zero elements of the matrix.

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OPTION_CONFLICT
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_ZERO_PIVOT

dss_solve_real, dss_solve_complex

Compute the corresponding solutions vector and place it in the output array.

Syntax

```
dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Description

For each right hand side column vector defined in the arrays *rRhsValues* or *cRhsValues*, these routines compute the corresponding solutions vector and place it in the arrays *rSolValues* or *cSolValues*.

The lengths of the right-hand side and solution vectors, *nCols* and *nRows* respectively, are assumed to have been defined in a previous call to [dss_define_structure](#).

Input Parameters

handle Data object of the MKL_DSS_HANDLE type (see [Interface Description](#)).

opt INTEGER. Options passing argument.

nRhs INTEGER. Number of the right-hand sides in the linear equation.

<i>rRhsValues</i>	DOUBLE PRECISION. Array of size <i>nRows</i> by <i>nRhs</i> . Contains real right-hand side vectors.
<i>cRhsValues</i>	DOUBLE COMPLEX. Array of size <i>nRows</i> by <i>nRhs</i> . Contains complex right-hand side vectors.

Output Parameters

<i>rSolValues</i>	DOUBLE PRECISION. Array of size <i>nCols</i> by <i>nRhs</i> . Contains real solution vectors.
<i>cSolValues</i>	DOUBLE COMPLEX. Array of size <i>nCols</i> by <i>nRhs</i> . Contains complex solution vectors.

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OUT_OF_MEMORY

dss_delete

Deletes all of data structures created during the solutions process.

Syntax

`dss_delete(handle, opt)`

Description

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

<i>opt</i>	INTEGER. Options passing argument. The default value is MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.

Output Parameters

handle Data object of the MKL_DSS_HANDLE type (see [Interface Description](#)).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

```
dss_statistics(handle, opt, statArr, retValues)
```

Description

The `dss_statistics` routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- problem solving duration,
- determinant of a matrix,
- inertia of a matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter *statArr*. The value of the statistics is returned in double precision in a return array allocated by user.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics must be requested only at the appropriate stages of the solving process. For example, inquiring about `FactorTime` before a matrix is factored leads to errors.

The following table shows the point at which each individual statistics item can be called:

Table 8-3 Statistics Calling Sequences

Type of Statistics	When to Call
<code>ReorderTime</code>	After <code>dss_reorder</code> is completed successfully.
<code>FactorTime</code>	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
<code>SolveTime</code>	After <code>dss_solve_real</code> or <code>dss_solve_complex</code> is completed successfully.
<code>Determinant</code>	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
<code>Inertia</code>	After <code>dss_factor_real</code> is completed successfully and the matrix is real, symmetric, and indefinite.
<code>Flops</code>	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
<code>Peakmem</code>	After <code>dss_reorder</code> is completed successfully.
<code>Factormem</code>	After <code>dss_reorder</code> is completed successfully.
<code>Solvemem</code>	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.

Input Parameters

<i>handle</i>	Data object of the <code>MKL_DSS_HANDLE</code> type (see Interface Description).								
<i>opt</i>	INTEGER. Options passing argument.								
<i>statArr</i>	STRING. Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): <table> <tr> <td><code>ReorderTime</code></td><td>Amount of time taken to do the reordering.</td></tr> <tr> <td><code>FactorTime</code></td><td>Amount of time taken to do the factorization.</td></tr> <tr> <td><code>SolveTime</code></td><td>Amount of time taken to solve the problem after factorization.</td></tr> <tr> <td><code>Determinant</code></td><td>Determinant of the matrix <i>A</i>.</td></tr> </table>	<code>ReorderTime</code>	Amount of time taken to do the reordering.	<code>FactorTime</code>	Amount of time taken to do the factorization.	<code>SolveTime</code>	Amount of time taken to solve the problem after factorization.	<code>Determinant</code>	Determinant of the matrix <i>A</i> .
<code>ReorderTime</code>	Amount of time taken to do the reordering.								
<code>FactorTime</code>	Amount of time taken to do the factorization.								
<code>SolveTime</code>	Amount of time taken to solve the problem after factorization.								
<code>Determinant</code>	Determinant of the matrix <i>A</i> .								

	For real matrices: the determinant is returned as <code>det_pow</code>, <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_base}) < 10.0$ and $\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}$. For complex matrices: the determinant is returned as <code>det_pow</code>, <code>det_re</code>, <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) < 10.0$ and $\text{determinant} = \text{det\_re} + \text{det\_im} * 10^{(\text{det\_pow})}$.
Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z), where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. <code>Inertia</code> is returned as three consecutive return array locations as p, n, z. Computing <code>Inertia</code> is recommended only for stable matrices. Unstable matrices can lead to incorrect results. <code>Inertia</code> of a k-by-k real symmetric positive definite matrix is always $(k, 0, 0)$. Therefore <code>Inertia</code> is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.
Flops	Number of floating point operations performed during the factorization.
Peakmem	Total peak memory in KBytes that the solver needs during the analysis and symbolic factorization phase.
Factormem	Permanent memory in KBytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.

Solvemem

Total double precision memory consumption (KBytes) of the solver for the factorization and solve phases.

NOTE. To avoid problems in passing strings from Fortran to C, Fortran users must call the `mkl_cvt_to_null_terminated_str` routine before calling `dss_statistics`. Refer to the description of [mkl_cvt_to_null_terminated_str](#) for details.

Output Parameters

retValues

DOUBLE PRECISION. Value of the statistics returned.

Finding “time used to reorder” and “inertia” of a matrix.

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValues)`, where *statArr* is “ReorderTime,Inertia”

In this example, *retValues* has the following values:

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATISTICS_INVALID_MATRIX

MKL_DSS_STATISTICS_INVALID_STATE

MKL_DSS_STATISTICS_INVALID_STRING

mkl_cvt_to_null_terminated_str

Passes character strings from Fortran routines to C routines.

Syntax

```
mkl_cvt_to_null_terminated_str (destStr, destLen, srcStr)
```

Description

The routine `mkl_cvt_to_null_terminated_str` passes character strings from Fortran routines to C routines. The strings are converted into integer arrays before being passed to C. Using this routine avoids the problems that can occur on some platforms when passing strings from Fortran to C. The use of this routine is highly recommended.

Input Parameters

<i>destLen</i>	INTEGER. Length of the output array <i>destStr</i> .
<i>srcStr</i>	STRING. Input string.

Output Parameters

<i>destStr</i>	INTEGER. One-dimensional array of integer.

Implementation Details

Several aspects of the Intel MKL DSS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, one of the following Intel MKL DSS language-specific header files can be included:

- `mkl_dss.f77` for F77 programs
- `mkl_dss.f90` for F90 programs
- `mkl_dss.h` for C programs

These header files define symbolic constants for error returns, function options, certain defined data types, and function prototypes.

NOTE. Constants for options, error returns, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

To simplify the use of the Intel MKL DSS routines, they do not require the user to allocate any temporary working storage. The solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using an opaque data object called a *handle*.

Each of the Intel MKL DSS routines creates, uses or deletes a handle. Consequently, user programs must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that should be used when declaring a handle object in the user code.

Fortran 90 programmers should declare a handle as:

```
INCLUDE "mkl_dss.f90"

TYPE (MKL_DSS_HANDLE) handle
```

C and C++ programmers should declare a handle as:

```
#include "mkl_dss.h"

_MKL_DSS_HANDLE_t handle;
```

FORTRAN 77 programmers using compilers that support eight byte integers, should declare a handle as:

```
INCLUDE "mkl_dss.f77"

INTEGER*8 handle
```

Otherwise they should replace the `INTEGER*8` data types with the `DOUBLE PRECISION` data type.

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the error returns
- user options for the solver routines
- message severity.

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel MKL supports the iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as . The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite

system (RCI Conjugate Gradient Solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI Flexible Generalized Minimal RESidual Solver, or RCI FGMRES) of linear algebraic equations and exploits the general RCI scheme described in [Dong95].

See the [Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

RCI means that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user himself must perform them and pass the result to the solver. This gives the great universality to the solver as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines (see [Sparse BLAS Level 2 and Level 3](#)).

NOTE. The RCI CG solver is implemented in two versions: for system of equations with single right hand side, and for system of equations with multiple right hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and positive definite.

The FGMRES method may fail if the matrix is degenerate.

Table 8-4 lists the names of the routines, and describes their general use.

Table 8-4 RCI ISS Interface Routines

Routine	Description
<code>dcg_init</code> , <code>dcgmrhs_init</code> , <code>dfgmres_init</code>	Initializes the solver.
<code>dcg_check</code> , <code>dcgmrhs_check</code> , <code>dfgmres_check</code>	Checks the consistency and correctness of the user defined data.
<code>dcg</code> , <code>dcgmrhs</code> , <code>dfgmres</code>	Computes the approximate solution vector.
<code>dcg_get</code> , <code>dcgmrhs_get</code> , <code>dfgmres_get</code>	Retrieves the number of the current iteration.

The Intel MKL RCI ISS interface routines are normally invoked in the order listed in [Table8-4](#), with the exception of `dcg_get`, `dcgmrhs_get`, and `dfgmres_get` routines that can be invoked at any place in the code. However, in this case some precautions should be taken to avoid the wrong results. Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram in [Figure 8-3](#) indicates the typical order in which the RCI ISS interface routines can be invoked.

Figure 8-3 Typical Order for Invoking RCI ISS interface Routines

The following pseudocode shows the general schemes of using the RCI CG routines.

...

generate matrix *A*

generate preconditioner *C* (optional)

call `dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)`

change parameters in *ipar*, *dpar* if necessary

call `dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)`

1 call `dcg(n, x, b, RCI_request, ipar, dpar, tmp)`

if (*RCI_request*.eq.1) then

multiply the matrix *A* by *tmp*(1:*n*,1) and put the result in *tmp*(1:*n*,2)

It is possible to use [MKL Sparse BLAS Level 2](#) subroutines for this operation

c proceed with CG iterations

goto 1

```

endif
if (RCI_request.eq.2)then
  do the stopping test
  if (test not passed) then
c  proceed with CG iterations
    go to 1
  else
c  stop CG iterations
    goto 2
  endif
endif
if (RCI_request.eq.3) then (optional)
  apply the preconditioner  $C$  inverse to  $tmp(1:n,3)$  and put the result in  $tmp(1:n,4)$ 
c  proceed with CG iterations
  goto 1
end
2 call dcg_get( $n, x, b, RCI\_request, ipar, dpar, tmp, itercount$ )
  current iteration number is in  $itercount$ 
  the computed approximation is in the array  $x$ 

```

And the following pseudocode shows the general schemes of using the RCI FGMRES routines.

...

generate matrix A

generate preconditioner C (optional)

```

  call dfgmres_init( $n, x, b, RCI\_request, ipar, dpar, tmp$ )
  change parameters in  $ipar, dpar$  if necessary
  call dfgmres_check( $n, x, b, RCI\_request, ipar, dpar, tmp$ )
1 call dfgmres( $n, x, b, RCI\_request, ipar, dpar, tmp$ )
  if ( $RCI\_request.eq.1$ ) then
    multiply the matrix  $A$  by  $tmp(ipar(22))$  and put the result in  $tmp(ipar(23))$ 

```

It is possible to use [MKL Sparse BLAS Level 2](#) subroutines for this operation

```

c  proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.2) then
    do the stopping test
    if (test not passed) then
c  proceed with FGMRES iterations
        go to 1
    else
c  stop FGMRES iterations
        goto 2
    endif
endif
if (RCI_request.eq.3) then (optional)
apply the preconditioner  $C$  inverse to  $tmp(ipar(22))$  and put the result in  $tmp(ipar(23))$ 
c  proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.4) then
check the norm of the next orthogonal vector, it is contained in  $dpar(7)$ 
    if (the norm is not zero up to rounding/computational errors) then
c  proceed with FGMRES iterations
        goto 1
    else
c  stop FGMRES iterations
        goto 2
    endif
endif
endif

```

2 call dfgmres_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

current iteration number is in *itercount*

the computed approximation is in the array *x*

Note that for the FGMRES method the array *x* initially contains the current initial approximation to the solution that can be updated only by calling the routine `dfgmres_get`. It updates the solution in accordance with the computations performed by the routine `dfgmres`.

The above pseudocodes demonstrate two main differences in the use of RCI CG and RCI FGMRES interfaces. The first difference relates to *RCI_request*=3 (different locations in the *tmp* array, which is 2-dimensional for CG and 1-dimensional for FGMRES). The second difference relates to *RCI_request*=4 (the RCI CG interface never produces *RCI_request*=4).

Code examples that use the RCI ISS interface routines to solve systems of linear equations can be found in the [Iterative Sparse Solver Code Example](#) section in the Appendix C.

CG Interface Description

All types in this documentation refer to the common Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section [Calling Sparse Solver and Preconditioner Routines From C/C++](#) for information on mapping Fortran types to C/C++ types.

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right hand side (SRHS), and for a system of equations with multiple right hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

NOTE. The routines for a system with MRHS can be used with the names without the suffix `mrhs`. To do this, the user must switch on the compiler preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Routines Options

All of the RCI CG routines have parameters for passing various options to the routines. The values for these parameters should be specified very carefully (see [CG Common Parameters](#)), and they can be changed during computations according to the user's needs.

NOTE. Provide correct and consistent parameters to the subroutines to avoid fails or wrong results.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `dcg` to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE. The default and initial values listed below are assigned to the parameters by calling the `dcg_init/dcgmrhs_init` routine.

<i>n</i>	- INTEGER, this parameter sets the size of the problem in the <code>dcg_init/dcgmrhs_init</code> routine. All the other routines uses the <code>ipar(1)</code> parameter instead.
<i>x</i>	- DOUBLE PRECISION array of size <i>n</i> for SRHS, or matrix of size <i>n</i> -by- <i>nrhs</i> for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>dcg/dcgmrhs</code> routine, it contains the initial approximation to the solution.
<i>nrhs</i>	- INTEGER, this parameter sets the number of right-hand sides for MRHS routines.
<i>b</i>	- DOUBLE PRECISION array containing a single right-hand side vector, or matrix (<i>nrhs</i> , <i>n</i>) containing right-hand side vectors.
<i>RCI_request</i>	- INTEGER, this parameter informs about the result of work of the RCI CG routines. The negative values of the parameter indicate that the routine is completed with errors or warnings. The 0 value indicates the successful completion of the task. The positive values mean that the user must perform certain actions, specifically: <i>RCI_request</i>= 1 - to multiply the matrix by <i>tmp</i> (1:<i>n</i>,1), put the result in <i>tmp</i>(1:<i>n</i>,2), and return the control to the <code>dcg/dcgmrhs</code> routine; <i>RCI_request</i>= 2 - to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. Otherwise, the solution is found and stored in the <i>x</i> array;

RCI_request= 3 - for SRHS: to apply the preconditioner to *tmp*(1:*n*,3), put the result in *tmp*(1:*n*,4), and return the control to the *dcg* routine;
 - for MRHS: to apply the preconditioner to *tmp*(:,3+*ipar*(3)), put the result in *tmp*(:,3), and return the control to the *dcgmrhs* routine.

Note that the *dcg_get*/*dcgmrhs_get* routine does not change the parameter *RCI_request*. This enables to use this routine inside the Reverse Communication computations.

ipar

- INTEGER array, of size 128 for SRHS, and of size (128+2**nrhs*) for MRHS; this parameter specifies the integer set of data for the RCI CG computations:

ipar(1) - specifies the size of the problem. The *dcg_init*/*dcgmrhs_init* routine assigns *ipar*(1)=*n*. All the other routines uses this parameter instead of *n*. There is no default value for this parameter.

ipar(2) - specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created files *dcg_errors.txt* and *dcg_check_warnings.txt* respectively. Note that if *ipar*(6) and *ipar*(7) parameters are set to 0, error and warning messages are not generated at all.

ipar(3) - for SRHS: contains the current stage of the RCI CG computations, the initial value is 1;
 - for MRHS: contains the right-hand side for which the calculations are currently performed.

WARNING. Avoid altering this variable during computations.

<i>ipar</i> (4)	- contains the current iteration number, the initial value is 0.
<i>ipar</i> (5)	- specifies the maximum number of iterations, the default value is $\min\{150, n\}$.
<i>ipar</i> (6)	- if the value is not equal to 0, the routines output error messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output error messages at all, but return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (7)	- if the value is not equal to 0, the routines output warning messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (8)	- if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine performs the stopping test for the maximum number of iterations, namely, $ipar(4) \leq ipar(5)$. Otherwise, the method is stopped and the corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the routine does not perform this stopping test. The default value is 1.
<i>ipar</i> (9)	- if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine performs the residual stopping test, namely, $dpar(5) \leq dpar(4) = dpar(1) * dpar(3) + dpar(2)$. Otherwise, the method is stopped and corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the routine does not perform this stopping test. The default value is 0.
<i>ipar</i> (10)	- if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine requests a user-defined stopping test by setting the output parameter

RCI_request=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE. At least one of the parameters *ipar*(8)-*ipar*(10) must be set to 1.

ipar(11) - if the value is equal to 0, the *dcg/dcgmrhs* routine runs the non-preconditioned version of the corresponding Conjugate Gradient method. Otherwise, the routine runs the preconditioned version of the Conjugate Gradient method, and requests the user to perform the preconditioning step by setting the output parameter *RCI_request*=3. The default value is 0.

ipar(11:128), are reserved and not used in the current RCI
ipar(11:128+2**nrhs*) CG SRHS and MRHS routines respectively.

NOTE. Advanced users can define the array in the code using RCI CG SRHS as `INTEGER ipar(11)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array *ipar* with length 128 is highly recommended.

dpar - DOUBLE PRECISION array, for SRHS of size 128, for MRHS of size (128+2**nrhs*); this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

dpar(1) - specifies the relative tolerance. The default value is 1.0D-6.

dpar(2) - specifies the absolute tolerance. The default value is 0.0D-0.

<code>dpar(3)</code>	- specifies the square norm of the initial residual (if it is computed in the <code>dcg/dcgmrhs</code> routine). The initial value is 0.
<code>dpar(4)</code>	- service variable equal to $dpar(1) * dpar(3) + dpar(2)$ (if it is computed in the <code>dcg/dcgmrhs</code> routine). The initial value is 0.
<code>dpar(5)</code>	- specifies the square norm of the current residual. The initial value is 0.0.
<code>dpar(6)</code>	- specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.
<code>dpar(7)</code>	- contains the <i>alpha</i> parameter of the CG method. The initial value is 0.0.
<code>dpar(8)</code>	- contains the <i>beta</i> parameter of the CG method, it is equal to $dpar(5) / dpar(6)$. The initial value is 0.0.
<code>dpar(9:128)</code> , <code>dpar(9:128+2*nrhs)</code>	are reserved and not used in the current RCI CG SRHS and MRHS routines respectively.

NOTE. Advanced users can define this array in the code using RCI CG SRHS as `DOUBLE PRECISION dpar(8)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array `dpar` with length 128 is highly recommended.

`tmp`

- DOUBLE PRECISION array of size $(n, 4)$ for SRHS, and $(n, 3+nrhs)$ for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

<code>tmp(:, 1)</code>	- specifies the current search direction. The initial value is 0.0.

<code>tmp(:, 2)</code>	- contains the matrix multiplied by the current search direction. The initial value is 0.0.
<code>tmp(:, 3)</code>	- contains the current residual. The initial value is 0.0.
<code>tmp(:, 4)</code>	- contains the inverse of the preconditioner applied to the current residual. There is no initial value for this parameter.

 **NOTE.** Advanced users can define this array in the code using RCI CG SRHS as `DOUBLE PRECISION tmp(n, 3)` if they run only non-preconditioned CG iterations.

FGMRES Interface Description

All types in this documentation refer to the common Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section [Calling Sparse Solver Routines From C/C++](#) for information on mapping Fortran types to C/C++ types.

Routines Options

All of the RCI FGMRES routines have parameters for passing various options to the routines. The values for these parameters should be specified very carefully (see [FGMRES Common Parameters](#)), and they can be changed during computations according to the user's needs.

 **NOTE.** Provide correct and consistent parameters to the subroutines to avoid fails or wrong results.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmres` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE. The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

<i>n</i>	- INTEGER, this parameter sets the size of the problem in the <code>dfgmres_init</code> routine. All the other routines uses <code>ipar(1)</code> parameter instead.
<i>x</i>	- DOUBLE PRECISION array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfgmres</code> routine, it contains the initial approximation to the solution vector.
<i>b</i>	- DOUBLE PRECISION array, this parameter contains the right-hand side vector. Depending on user requests, it may later contain the approximate solution.
<i>RCI_request</i>	- INTEGER, this parameter informs about the result of work of the RCI FGMRES routines. The negative values of the parameter indicate that the routine is completed with errors or warnings. The 0 value indicates the successful completion of the task. The positive values mean that the user must perform certain actions, specifically: <i>RCI_request</i> = 1 - multiply the matrix by <code>tmp(ipar(22))</code>, put the result in <code>tmp(ipar(23))</code>, and return the control to the <code>dfgmres</code> routine; <i>RCI_request</i> = 2 - perform the stopping tests. If they fail, return the control to the <code>dfgmres</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;

	<i>RCI_request</i> = 3	- apply the preconditioner to <i>tmp(ipar(22))</i> , put the result in <i>tmp(ipar(23))</i> , and return the control to the <i>dfgmres</i> routine.
	<i>RCI_request</i> = 4	- check if the norm of the current orthogonal vector is not zero within the rounding/computational errors. Return the control to the <i>dfgmres</i> routine if it is not zero, otherwise complete the solution process by calling <i>dfgmres_get</i> routine.
<i>ipar</i> (128)		- INTEGER array, this parameter specifies the integer set of data for the RCI FGMRES computations:
<i>ipar</i> (1)		- specifies the size of the problem. The <i>dfgmres_init</i> routine assigns <i>ipar</i> (1)= <i>n</i> . All the other routines uses this parameter instead of <i>n</i> . There is no default value for this parameter.
<i>ipar</i> (2)		- specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file <i>MKL_RCI_FGMRES_Log.txt</i> . Note that if <i>ipar</i> (6) and <i>ipar</i> (7) parameters are set to 0, error and warning messages are not generated at all.
<i>ipar</i> (3)		- contains the current stage of the RCI FGMRES computations, the initial value is 1.
		 WARNING. Avoid altering this variable during computations.
<i>ipar</i> (4)		- contains the current iteration number. The initial value is 0.

<i>ipar</i> (5)	- specifies the maximum number of iterations. The default value is $\min\{150, n\}$.
<i>ipar</i> (6)	- if the value is not equal to 0, the routines output error messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output error messages at all, but return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (7)	- if the value is not equal to 0, the routines output warning messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (8)	- if the value is not equal to 0, the <i>dfgmres</i> routine performs the stopping test for the maximum number of iterations, namely, $ipar(4) \leq ipar(5)$. Otherwise, the method is stopped and the corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the <i>dfgmres</i> routine does not perform this stopping test. The default value is 1.
<i>ipar</i> (9)	- if the value is not equal to 0, the <i>dfgmres</i> routine performs the residual stopping test, namely, $dpar(5) \leq dpar(4) = dpar(1) \cdot dpar(3) + dpar(2)$. If the criterion is met, the method is stopped and corresponding value is assigned to the output parameter <i>RCI_request</i> . If the value is 0, the <i>dfgmres</i> routine does not perform this stopping test. The default value is 0.
<i>ipar</i> (10)	- if the value is not equal to 0, the <i>dfgmres</i> routine requests for the user defined stopping test by setting <i>RCI_request</i> =2. If the value

is 0, the `dfgmres` routine does not perform the user defined stopping test. The default value is 1.

NOTE. At least one of the parameters $ipar(8)$ - $ipar(10)$ must be set to 1.

<code>ipar(11)</code>	- if the value is equal to 0, the <code>dfgmres</code> routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests the user to perform the preconditioning step by setting the output parameter <code>RCI_request=3</code> . The default value is 0.
<code>ipar(12)</code>	- if the value is not equal to 0, the <code>dfgmres</code> routine performs the automatic test for zero norm of the currently generated vector, namely, $dpar(7) \leq dpar(8)$, where $dpar(8)$ contains the tolerance value. Otherwise, the routine requests the user to perform this check by setting the output parameter <code>RCI_request=4</code> . The default value is 0.
<code>ipar(13)</code>	- if the value is equal to 0, the <code>dfgmres_get</code> routine updates the solution to the vector x according to the computations done by the <code>dfgmres</code> routine. If the value is positive, the routine writes the solution to the right hand side vector b . If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0

NOTE. Advanced users may use the `dfgmres_get` routine at any place in the code. In this case special attention should be paid to the parameter `ipar(13)`. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter `ipar(13)` is not equal to zero. If `ipar(13)` is positive, then the updated solution overwrites the right hand side in the vector *b*. If the user wants to run the restarted version of FGMRES with the same right hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive `ipar(13)`.

`ipar(14)`

- contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING. Avoid altering this variable during computations.

`ipar(15)`

- specifies the length of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, the user must assign the number of iterations to `ipar(15)` before the restart. The default value is $\min\{150, n\}$, that is, by default the non-restarted version of FGMRES method is used.

`ipar(16)`

- service variable, specifies the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see [Matrix Arguments](#) in the Appendix B for details) is started in the *tmp* array.

<i>ipar</i> (17)	- service variable, specifies the location of the rotation cosines from which the vector of cosines is started in the <i>tmp</i> array.
<i>ipar</i> (18)	- service variable, specifies the location of the rotation sines from which the vector of sines is started in the <i>tmp</i> array.
<i>ipar</i> (19)	- service variable, specifies the location of the rotated residual vector from which the vector is started in the <i>tmp</i> array.
<i>ipar</i> (20)	- service variable, specifies the location of the least squares solution vector from which the vector is started in the <i>tmp</i> array.
<i>ipar</i> (21)	- service variable, specifies the location of the set of preconditioned vectors from which the set is started in the <i>tmp</i> array. The memory locations in the <i>tmp</i> array starting from <i>ipar</i> (21) are used only for the preconditioned FGMRES method.
<i>ipar</i> (22)	- specifies the memory location from which the first vector (source) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.
<i>ipar</i> (23)	- specifies the memory location from which the second vector (source) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.
<i>ipar</i> (24:128)	are reserved and not used in the current RCI FGMRES routines.

NOTE. Advanced users can define the array in the code as `INTEGER ipar(23)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array *ipar* with length 128 is highly recommended.

<i>dpar</i> (128)	- DOUBLE PRECISION array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:
<i>dpar</i> (1)	- specifies the relative tolerance. The default value is 1.0D-6.
<i>dpar</i> (2)	- specifies the absolute tolerance. The default value is 0.0D-0.
<i>dpar</i> (3)	- specifies the Euclidean norm of the initial residual (if it is computed in the <i>dfgmres</i> routine). The initial value is 0.0.
<i>dpar</i> (4)	- service variable equal to $dpar(1) * dpar(3) + dpar(2)$ (if it is computed in the <i>dfgmres</i> routine). The initial value is 0.0.
<i>dpar</i> (5)	- specifies the Euclidean norm of the current residual. The initial value is 0.0.
<i>dpar</i> (6)	- specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.
<i>dpar</i> (7)	- contains the norm of the generated vector. The initial value is 0.0.
 NOTE. For reference only: in terms of [Saad03] this parameter is the coefficient $h_{k+1,k}$ of the Hessenberg matrix.	
<i>dpar</i> (8)	- contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0D-12.
<i>dpar</i> (9:128)	are reserved and not used in the current RCI FGMRES routines.

NOTE. Advanced users can define this array in the code as follows: `DOUBLE PRECISION dpar(8)`. However, to guarantee compatibility with the future releases of Intel MKL, declaring the array `dpar` with length 128 is highly recommended.

tmp

-DOUBLE PRECISION array of size $((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1))$, this parameter is used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

tmp(1:ipar(16)-1) - contains the sequence of generated by the FGMRES method vectors. The initial value is 0.0 for the first part of this memory of length *n*;

tmp(ipar(16):ipar(17)-1) contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of *tmp* array.

tmp(ipar(17):ipar(18)-1) - contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

tmp(ipar(18):ipar(19)-1) contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

tmp(ipar(19):ipar(20)-1) contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.

tmp(ipar(20):ipar(21)-1) contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of *tmp* array.

`tmp(ipar(21) :)` contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of `tmp` array is not used if non-preconditioned version of FGMRES method is called. There is no initial value for this part of `tmp` array.

NOTE. Advanced users can define this array in the code as `DOUBLE PRECISION tmp((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1))` if they run only non-preconditioned FGMRES iterations.

dcg_init

Initializes the solver.

Syntax

```
dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set these parameters directly in the corresponding routines.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	INTEGER. Contains the size of the problem, and the sizes of arrays x and b .
x	DOUBLE PRECISION array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
b	DOUBLE PRECISION array of size n . Contains the right-hand side vector.

Output Parameters

$RCI\_request$	INTEGER. Informs about result of work of the routine.
$ipar$	INTEGER array of size 128. Refer to the CG Common Parameters .
$dpar$	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
tmp	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

$RCI\_request = 0$	The routine completes the task normally.
$RCI\_request = -10000$	The routine fails to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

`dcg_check( $n$ ,  $x$ ,  $b$ ,  $RCI\_request$ ,  $ipar$ ,  $dpar$ ,  $tmp$ )`

Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the method. Advanced users may skip this operation if they are sure that the correct data is specified in the solver parameters.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcg_init` routine.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and size of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request= 0</code>	The routine completes task normally.
<code>RCI_request= -1100</code>	The routine is interrupted, errors occur.
<code>RCI_request= -1001</code>	The routine returns some warning messages.
<code>RCI_request= -1010</code>	The routine changes some parameters to make them consistent or correct.
<code>RCI_request= -1011</code>	The routine returns some warning messages and changes some parameters.

dcg

Computes the approximate solution vector.

Syntax

```
dcg(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

The routine `dcg` computes the approximate solution vector using the CG method [Young71]. , The routine `dcg` uses the value that was in the vector `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` informs the user about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcg_init` routine.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and size of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the initial approximation to the solution vector.
<code>b</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the right-hand side vector.
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the updated approximation to the solution vector.
<i>ipar</i>	INTEGER array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> =0	The routine completes task normally, the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the comments to the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	The routine is interrupted because the maximal number of iterations is reached, but the relative stopping criterion is not met - this situation occurs only if both tests are requested by the user.
<i>RCI_request</i> =-2	The routine is interrupted because attempt to divide by zero occurs. This situation happens if the matrix is (almost) non-positive definite.
<i>RCI_request</i> =- 10	The routine is interrupted because the residual norm is invalid. Probably, the value <i>dpar</i> (6) was altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> =-11	The routine is interrupted because it enters the infinite cycle. Probably, the values <i>ipar</i> (8), <i>ipar</i> (9), <i>ipar</i> (10) were altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> = 1	Requests the user to multiply the matrix by <i>tmp</i> (1: <i>n</i> ,1), put the result in the <i>tmp</i> (1: <i>n</i> ,2), and return the control back to the routine <i>dcg</i> .

`RCI_request= 2`

Requests the user to perform the stopping tests. If they fail, the control must be returned back to the `dcg` routine. Otherwise, the solution is found and stored in the vector `x`.

`RCI_request= 3`

Requests the user to apply the preconditioner to `tmp(:, 3)`, put the result in the `tmp(:, 4)`, and return the control back to the routine `dcg`.

dcg_get

Retrieves the number of the current iteration.

Syntax

`dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Description

The routine `dcg_get` retrieves the current iteration number of the solutions process.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and the sizes of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the initial approximation vector to the solution.
<code>b</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the right-hand side vector.
<code>RCI_request</code>	INTEGER. This parameter is not used.
<code>ipar</code>	INTEGER array of size 128. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Output Parameters

itercount INTEGER argument. Contains the value of the current iteration number.

Return Values

The routine `dcg_get` does not return any value.

dcgmrhs_init

Initializes the RCI CG solver with MHRS.

Syntax

```
dcgmrhs_init(n, x, nrhs, b, method, RCI_request, ipar, dpar, tmp)
```

Description

The routine `dcgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right hand sides (MRHS) routines use the values of all parameters that are returned by `dcgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the corresponding routines.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

NOTE. To use this routine with the name `dcg_init`, switch on the compiler preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

n INTEGER. Contains the size of the problem, and the sizes of arrays *x* and *b*.

x DOUBLE PRECISION matrix of size *n*-by-*nrhs*. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to *b*.

<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size $(nrhs, n)$. Contains the right-hand side vectors.
<i>method</i>	INTEGER. Specifies the method of solution: 1 - CG with multiple right hand sides; default value 2 - Block-CG (not supported now).

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.
<i>RCI_request</i> = -10000	The routine fails to complete the task.

dcgmrhs_check

Checks consistency and correctness of the user defined data.

Syntax

```
dcgmrhs_check(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)
```

Description

The routine `dcgmrhs_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcgmrhs`. However this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the method. Advanced users may skip this operation if they are sure that the correct data is specified in the solver parameters.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

NOTE. To use this routine with the name `dcg_check`, switch on the compiler preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION matrix of size <i>n</i> by <i>nrhs</i> . Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <i>b</i> .
<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size (<i>nrhs</i> , <i>n</i>). Contains the right-hand side vectors.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size (<i>128+2*nrhs</i>). Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size (<i>n</i> , <i>3+nrhs</i>). Refer to the CG Common Parameters .

Return Values

RCI_request= 0 The routine completes task normally.

<code>RCI_request= -1100</code>	The routine is interrupted, errors occur.
<code>RCI_request= -1001</code>	The routine returns some warning messages.
<code>RCI_request= -1010</code>	The routine changes some parameters to make them consistent or correct.
<code>RCI_request= -1011</code>	The routine returns some warning messages and changes some parameters.

dcgmrhs

Computes the approximate solution vectors.

Syntax

`dcgmrhs(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)`

Description

The routine `dcgmrhs` computes the approximate solution vectors using the CG with multiple right hand sides (MRHS) method [Young71]. The routine `dcgmrhs` uses the value that was in the `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` informs the user about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

NOTE. To use this routine with the name `dcg`, the user must switch on the compiler's preprocessor and include the files `mkl_solver.h` for C/C++, or `mkl_solver.f77` for FORTRAN.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and the sizes of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION matrix of size <code>n-by-nrhs</code> . Contains the initial approximation to the solution vectors.
<code>nrhs</code>	INTEGER. This parameter sets the number of right-hand sides.

<i>b</i>	DOUBLE PRECISION matrix of size $(nrhs, n)$. Contains the right-hand side vectors.
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>x</i>	DOUBLE PRECISION matrix of size n -by- $nrhs$. Contains the updated approximation to the solution vectors.
<i>ipar</i>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> =0	The routine completes task normally, the solution is found and stored in the matrix <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the comments to the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	The routine is interrupted because the maximal number of iterations is reached, but the relative stopping criterion is not satisfied. This situation occurs only if both tests are requested by the user.
<i>RCI_request</i> =-2	The routine is interrupted because attempt to divide by zero occurs. This happens if the matrix is (almost) non-positive definite.
<i>RCI_request</i> =- 10	The routine is interrupted because the residual norm is invalid. Probably, the value <i>dpar</i> (6) was altered outside of the routine, or the routine <i>dpgmrhs_check</i> was not called.

`RCI_request=-11`

The routine is interrupted because it enters the infinite cycle. Probably, the values `ipar(8)`, `ipar(9)`, `ipar(10)` were altered outside of the routine, or the routine `dcgmrhs_check` was not called.

`RCI_request= 1`

Requests the user to multiply the matrix by `tmp(1:n,1)`, put the result in the `tmp(1:n,2)`, and return the control back to the routine `dcgmrhs`.

`RCI_request= 2`

Requests the user to perform the stopping tests. If they fail, the control must be returned back to the routine `dcgmrhs`. Otherwise, the solution is found and stored in the matrix `x`.

`RCI_request= 3`

Requests the user to apply the preconditioner to `tmp(:,3+ipar(3))`, put the result in `tmp(:,3)`, and return the control back to the routine `dcgmrhs`.

dcgmrhs_get

Retrieves the number of the current iteration.

Syntax

`dcgmrhs_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Description

The routine `dcgmrhs_get` retrieves the current iteration number of the solving process.

NOTE. To use this routine with the name `dcg_get`, switch on the compiler preprocessor and include the files `mk1_solver.h` for C/C++, or `mk1_solver.f77` for FORTRAN.

Input Parameters

<code>n</code>	INTEGER. Contains the size of the problem, and the sizes of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION matrix of size <code>n</code> -by- <code>nrhs</code> . Contains the initial approximation to the solution vectors.

<i>nrhs</i>	INTEGER. This parameter sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size $(nrhs, n)$. Contains the right-hand side .
<i>RCI_request</i>	INTEGER. This parameter is not used.
<i>ipar</i>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	INTEGER argument. Contains the value of the current iteration number.

Return Values

The routine `dcgmrhs_get` does not return any value.

dfgmres_init

Initializes the solver.

Syntax

```
dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users may skip this step and set the values to these parameters directly in the corresponding routines.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	INTEGER. Contains the size of the problem, and the sizes of arrays x and b .
x	DOUBLE PRECISION array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
b	DOUBLE PRECISION array of size n . Contains the right-hand side vector.

Output Parameters

$RCI\_request$	INTEGER. Informs about result of work of the routine.
$ipar$	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
$dpar$	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
tmp	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

$RCI\_request = 0$	The routine completes task normally.
$RCI\_request = -10000$	The routine fails to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

`dfgmres_check( $n$ ,  $x$ ,  $b$ ,  $RCI\_request$ ,  $ipar$ ,  $dpar$ ,  $tmp$ )`

Description

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the method. Advanced users may skip it if they are sure that the correct data is specified in the solver parameters.

WARNING. Users can modify the contents of these arrays after they are passed to the solver routine only if they are sure that the values are correct and consistent. Basic check for correctness and consistency can be done by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2 * ipar(15) + 1) * n + ipar(15) * ipar(15) + 9) / 2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<code>RCI_request= 0</code>	The routine completes task normally.
<code>RCI_request= -1100</code>	The routine is interrupted, errors occur.
<code>RCI_request= -1001</code>	The routine returns some warning messages.
<code>RCI_request= -1010</code>	The routine changes some parameters to make them consistent or correct.
<code>RCI_request= -1011</code>	The routine returns some warning messages and changes some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

```
dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
```

Description

The routine `dfgmres` performs the FGMRES iterations [Saad03]. The routine `dfgmres` uses the value that was in the vector x before the first call as an initial approximation to the solution. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter `ipar(13)` is not equal to 0 (default value). Note that the updated solution overwrites the right hand side in the vector b if the parameter `ipar(13)` is positive, and the restarted version of the FGMRES method can not be run. If the right hand side should be kept, it must be saved in a different memory location before the first call to the `dfgmres_get` routine with a positive `ipar(13)`.

The parameter `RCI_request` informs the user about the task completion and requests results of certain operations that are needed to the solver.

Note that lengths of all the vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

Input Parameters

`n` INTEGER. Contains the size of the problem, and the sizes of arrays x and b .

<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector.
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> = 0	The routine completes task normally, the solution is found. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the comments to the <i>RCI_request</i> = 2 or 4.
<i>RCI_request</i> = -1	The routine is interrupted because the maximal number of iterations is reached, but the relative stopping criterion is not met. This situation occurs only if both tests are requested by the user.
<i>RCI_request</i> = -10	The routine is interrupted because attempt to divide by zero occurs. Normally it happens if the matrix is (almost) degenerate. However it may happen if the parameter <i>dpar</i> is altered by mistake, or if the method is not stopped when the solution is found.

`RCI_request= -11`

The routine is interrupted because it enters the infinite cycle. Probably, the values `ipar(8)`, `ipar(9)`, `ipar(10)` were altered outside of the routine, or the `dfgmres_check` routine was not called.

`RCI_request= -12`

The routine is interrupted because errors are found in the method parameters. Normally this happens if the parameters `ipar` and `dpar` are altered by mistake outside the routine.

`RCI_request= 1`

Requests the user to multiply the matrix by `tmp(ipar(22))`, put the result in the `tmp(ipar(23))`, and return the control back to the routine `dfgmres`.

`RCI_request= 2`

Requests the user to perform the stopping tests. If they fail, the control back must be returned to the `dfgmres` routine. Otherwise, the FGMRES solution is found, and the `fgmres_get` routine can be run to update the computed solution in the vector `x`.

`RCI_request= 3`

Requests the user to apply the inverse preconditioner to `ipar(22)`, put the result in the `ipar(23)`, and return the control back to the routine `dfgmres`.

`RCI_request= 4`

Requests the user to check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, the control must be returned back to the `dfgmres` routine. Otherwise, the FGMRES solution is found, and the `dfgmres_get` routine can be run to update the computed solution in the vector `x`.

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

`dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Description

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter `ipar(13) = -1` beforehand. This is normally recommended to do to proceed further with the computations. If the intermediate solution is needed, the method parameters must be set properly, see for details [FGMRES Common Parameters](#) and [Iterative Sparse Solver Code Examples](#) section in the Appendix C.

Input Parameters

<i>n</i>	INTEGER. Contains the size of the problem, and the sizes of the arrays <i>x</i> and <i>b</i> .
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n+ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Output Parameters

<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . If <code>ipar(13) = 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . If <code>ipar(13) > 0</code> , it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>itercount</i>	INTEGER argument. Contains the value of the current iteration number.

Return Values

<i>RCI_request</i> = 0	The routine completes task normally.

`RCI_request= -12`

The routine is interrupted because errors are found in the method parameters. Normally this happens if the parameters *ipar* and *dpar* are altered by mistake outside the routine.

`RCI_request= -10000`

The routine fails to complete the task.

Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files. Currently, there is one language specific header file for C programs.

This language-specific header file defines function prototypes and they are the following:

```
void dcg_init(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);
```

```
void dcg_check(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);
```

```
void dcg(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp);
```

```
void dcg_get(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp, int *itercount);
```

```
void dcgmrhs_init(int *n, double *x, int *nRhs, double *b, int *method, int
*rci_request, int *ipar, double dpar, double *tmp);
```

```
void dcgmrhs_check(int *n, double *x, int *nRhs, double *b, int *rci_request,
int *ipar, double dpar, double *tmp);
```

```
void dcgmrhs(int *n, double *x, int *nRhs, double *b, int *rci_request, int
*ipar, double dpar, double *tmp);
```

```
void dcgmrhs_get(int *n, double *x, int *nRhs, double *b, int *rci_request,
int *ipar, double dpar, double *tmp, int *itercount);
```

```
void dfgmres_init(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);
```

```
void dfgmres_check(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);
```

```
void dfgmres(int *n, double *x, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);
```

```
void dfgmres_get(int *n, double *x, double *b, int *rci_request, int *ipar,  
double dpar, double *tmp, int *itercount);
```

NOTE. Intel MKL does not support the RCI ISS interface without the language specific header file included.

Preconditioners based on Incomplete LU Factorization Technique

Usually, preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms 'preconditioner' and 'accelerator' are synonyms, hereafter only 'preconditioner' is used.

Currently, Intel MKL provides two preconditioners, ILU0 and ILUT, for the sparse matrix presented only in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format, see [Sparse Matrix Storage Format](#) section). The used algorithms are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: low triangular and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT preconditioner is that it saves the resulting entry of the preconditioner if the entry satisfies two conditions simultaneously: the value of the entry is greater than the product of the given tolerance and matrix row norm, and the entry is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using this preconditioners with MKL RCI CG solver because in general, they produce non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine [mkl_dcsrtrsv](#) must be applied twice: for the low triangular part of the preconditioner, and then for its upper triangular part.

NOTE. Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. The result of the preconditioner routine can be checked only in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial guess, and even ruin the convergence. It is user's responsibility to carefully use a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The scheme is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. All these differences can be seen in the example codes for both preconditioners in the [Preconditioner Code Examples](#) in the Appendix C.

The following pseudocode shows the general scheme of using the ILUT preconditioner in the RCI FGMRES context.

```
...
generate matrix A
generate preconditioner C (optional)
    call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
    change parameters in ipar, dpar if necessary
    call dcsrilut(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar,
ierr)
    call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1  call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
    if (RCI_request.eq.1) then
        multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
c  proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.2) then
    do the stopping test
```

```

        if (test not passed) then
c   proceed with FGMRES iterations
            go to 1
        else
c   stop FGMRES iterations.
            goto 2
        endif
    endif

    if (RCI_request.eq.3) then
c   Below, trvec is an intermediate vector of length at least n
c   Here is the recommended use of the result produced by the ILUT routine.
c   via standard Intel MKL Sparse Blas solver routine mkl_dcsrtrsv.
        call mkl_dcsrtrsv('L','N','U', n, bilut, ibilut, jbilut,
            tmp(ipar(22)), trvec)

        call mkl_dcsrtrsv('U','N','N', n, bilut, ibilut, jbilut, trvec,
            tmp(ipar(23)))
c   proceed with FGMRES iterations
            goto 1
        endif

    if (RCI_request.eq.4) then
        check the norm of the next orthogonal vector, it is contained in dpar(7)
        if (the norm is not zero up to rounding/computational errors) then
c   proceed with FGMRES iterations
            goto 1
        else
c   stop FGMRES iterations
            goto 2
        endif
    endif

```

```
endif
2 call dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
current iteration number is in itercount
the computed approximation is in the array x
```

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the [Linear Solvers Basics](#).

In this section the FORTRAN style notations are used.

All types in this documentation refer to the standard Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section [Calling Sparse Solver Routines From C/C++](#) for information on mapping Fortran types to C/C++ types.

User Data Arrays

The preconditioner routines take arrays of user data as input, for example, user arrays representing the original matrix. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

Common Parameters

The preconditioners have parameters for passing various options to the routine. The values for these parameters should be specified very carefully. These values can be changed during computations according to the user's needs.

Some parameters are common with the [FGMRES Common Parameters](#). Only the routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

`ipar(2)` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise the error messages are written to the newly created file `MKL_PREC_log.txt`. Note if the parameter `ipar(6)` is set to 0, then error messages are not generated at all.

ipar(6) - if its value is not equal to 0, the ILU0 routine returns error messages in accordance with the parameter *ipar(2)*. Otherwise, the routine does not generate error messages at all, but returns a negative value of the parameter *ierr*. The default value is 1.

For the ILUT preconditioner:

ipar(2) - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise the error messages are written to the newly created file `MKL_PREC_log.txt`. Note if the parameter *ipar(6)* is set to 0, error messages are not generated at all.

ipar(6) - if its value is not equal to 0, the ILUT routine returns error messages in accordance with the parameter *ipar(2)*. Otherwise, the routine does not generate error messages at all, but returns a negative value of the parameter *ierr*. The default value is 1.

ipar(7) - if its value is greater than 0, the ILUT routine generates warning messages in accordance with the parameter *ipar(2)* and continues calculations. Otherwise, if its value is equal to 0, the routine returns a positive value of the parameter *ierr*, if its value is less than 0, the routine generates a warning message in accordance with the parameter *ipar(2)* and returns a positive value of the parameter *ierr*. The default value is 1.

NOTE. Users must provide correct and consistent parameters to the routine to avoid fails or wrong results.

dcsrilu0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix in the CSR format (PARDISO variation).

Syntax

Fortran:

```
call dcsrilu0(n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

C:

```
dcsrilu0(&n, a, ia, ja, bilu0, ipar, dpar, &ierr);
```

Input Parameters

n	INTEGER. Size (number of rows or columns) of the original square n -by- n -matrix A .
a	DOUBLE PRECISION. Array containing the set of elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to values array description in the Sparse Matrix Storage Format section for more details.
ia	INTEGER. Array of size $(n+1)$ containing begin indices of rows of matrix A such that $ia(I)$ is the index in the array A of the first non-zero element from the row I . The value of the last element $ia(n+1)$ is equal to the number of non-zeros in the matrix A plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format section for more details.
ja	INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its size is equal to the size of the array a . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format section for more details.

NOTE. Column indices should be put in increasing order for each row of matrix.

$ipar$ INTEGER array of size 128. This parameter is used to specify the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the $ipar$ array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

$ipar(31)$ - specifies how the routine operates if zero diagonal element occurs during calculation. If this parameter is set to 0 (default value set by the routine `dfgmres_init`) then that the calculations are stopped and the routine returns non-zero error value. Otherwise the value

of the diagonal element is set to the specified value and the calculations are continued.

NOTE. Advanced users can define this array in the code as follows:
`INTEGER ipar(31)`. However, to guarantee the compatibility with the future releases of the Intel MKL it is highly recommended to declare the array *ipar* of length 128.

dpar

DOUBLE PRECISION array of size 128. This parameter is used to specify the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

dpar(31)

- specifies the small value that is compared with the diagonal elements during calculations; if the value of the diagonal element is smaller, then it is set to *dpar*(32), or the calculations are stopped, in accordance with *ipar*(31); the default value is 1.0D-16

NOTE. This parameter can be set to the negative value, because its absolute value is actually used in calculations.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

`dpar(32)`

- specifies the value that is assigned to the diagonal element if its value is less than `dpar(31)` (see above); the default value is 1.0D-10

NOTE. Advanced users can define this array in the code as follows:

```
DOUBLE PRECISION dpar(32).
```

However, to guarantee the compatibility with the future releases of the Intel MKL it is highly recommended to declare the array `dpar` of length 128.

Output Parameters

`bilu0`

DOUBLE PRECISION. Array *B* stored in the PARDISO CSR format containing non-zero elements of the resulting preconditioning matrix. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details.

`ierr`

INTEGER. Error flag, informs about the routine completion status.

NOTE. To present the resulting preconditioning matrix in the CSR format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Description

The routine `dcsrilu0` computes a preconditioner *B* [Saad03] of a given sparse matrix *A* stored in the CSR format accepted in PARDISO:

$A \sim B = L * U$, where *L* is a low triangular matrix with unit diagonal, *U* is an upper triangular matrix with non-unit diagonal, and the portrait of the original matrix *A* is used to store the incomplete factors *L* and *U*.

Return Values

`ierr=0`

The routine completed task normally.

`ierr=-101`

The routine is interrupted, the error occurs: at least one diagonal element is omitted from the matrix in CSR format (see [Sparse Matrix Storage Format](#)).

`ierr=-102`

The routine is interrupted because the matrix contains zero diagonal element, routine can not perform operations.

`ierr=-103`

The routine is interrupted as the matrix contains too small diagonal element, and an overflow may occur because of the division by its value required to complete the task, or a bad approximation to ILU0 with use of this element will be computed.

`ierr=-104`

The routine is interrupted because the memory is insufficient for the internal work array.

`ierr=-105`

The routine is interrupted because the input matrix size n is less than or equal to 0.

`ierr=-106`

The routine is interrupted because the column indices ja are placed in not increasing order.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilu0 (n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

```
INTEGER n, ierr, ipar(128)
```

```
INTEGER ia(*), ja(*)
```

```
DOUBLE PRECISION a(*), bilu0(*), dpar(128)
```

C:

```
void dcsrilu0 (int *n, double *a, int *ia, int *ja, double *bilu0, int *ipar, double *dpar,
int *ierr);
```

dcsrilut

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

Fortran:

```
call dcsrilut(n, a, ia, ja, bilut, bilut, ibilut, jbilut, tol, maxfil, ipar,
dpar, ierr)
```

C:

```
dcsrilut(&n, a, ia, ja, bilut, bilut, ibilut, jbilut, &tol, &maxfil, ipar,
dpar, &ierr);
```

Description

The routine `dcsrilut` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$, where L is a low triangular matrix with unit diagonal, U is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors L and U :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter `tol`, and
- 2) the number of the non-zero elements in each row of the resulting L and U factors must not be greater than the value of the parameter `maxfil`.

Input Parameters

<i>n</i>	INTEGER. Size (number of rows or columns) of the original square n -by- n matrix A .
<i>a</i>	DOUBLE PRECISION. Array containing all non-zero elements of the matrix A . The length of the array is equal to their number. Refer to <i>values</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ia</i>	INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array A . $ia(I)$ is the index of the first non-zero element from the row I . The value of the last

element $ia(n+1)$ is equal to the number of non-zeros in the matrix A plus one. Refer to the *rowIndex* array description in the [Sparse Matrix Storage Format](#) section for more details.

ja

INTEGER. Array of size equal to the size of the array *a*. This array contains the column numbers for each non-zero element of the matrix A . Refer to the *columns* array description in the [Sparse Matrix Storage Format](#) section for more details.

NOTE. Column numbers must be in increasing order for each row of matrix.

tol

DOUBLE PRECISION. Tolerance for threshold criterion for the resulting entries of the preconditioner.

maxfil

INTEGER. Maximum fill-in, half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner can not exceed $(2*maxfil+1)$.

ipar

INTEGER array of size 128. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

ipar(31)

- specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*(31) = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to the certain value (see description of the parameter *dpar*(31) below), and the calculation continues.

NOTE. There is no default value for *ipar*(31) entry even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE. Advanced users can define this array in the code as `INTEGER ipar(31)`. However, to guarantee the compatibility with the future releases of the Intel MKL, declare the array *ipar* of length 128.

dpar

DOUBLE PRECISION array of size 128. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

dpar(31)

- specifies the value that being multiplied by the matrix row norm is assigned to those diagonal elements whose value is less than the matrix row norm multiplied by the value of the parameter *tol*, if the calculation is not stopped in accordance with *ipar*(31).

NOTE. There is no default value for *dpar*(31) entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE. Advanced users can define this array in the code as `DOUBLE PRECISION dpar(31)`. However, to guarantee the compatibility with the future releases of the Intel MKL, declare the array `dpar` of length 128.

Output Parameters

bilut

DOUBLE PRECISION. Array *B* containing non-zero elements of the resulting preconditioning matrix, stored format accepted in the direct sparse solvers. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details. The size of the array is equal to $(2*maxfil+1)*n-maxfil*(maxfil+1)+1$.

NOTE. Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

ibilut

INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array *B*. *ibilut(I)* is the index of the first non-zero element from the row *I*. The value of the last element *ibilut(n+1)* is equal to the number of non-zeros in the matrix *B* plus one. Refer to the *rowIndex* array description in the [Sparse Matrix Storage Format](#) section for more details..

jbilut

INTEGER. Array, its size is equal to the size of the array *bilut*. This array contains the column numbers for each non-zero element of the matrix *B*. Refer to the *columns* array description in the [Sparse Matrix Storage Format](#) section for more details.

ierr

INTEGER. Error flag, informs about the routine completion.

Return Values

ierr=0

The routine completes the task normally.

<code>ierr=-101</code>	The routine is interrupted, the error occurs: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
<code>ierr=-102</code>	The routine is interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <code>ipar(31)=0</code> .
<code>ierr=-103</code>	The routine is interrupted, the error occurs: the element <code>ia(I+1)</code> is less than or equal to the element <code>ia(I)</code> (see Sparse Matrix Storage Format section).
<code>ierr=-104</code>	The routine is interrupted because the memory is insufficient for the internal work arrays.
<code>ierr=-105</code>	The routine is interrupted because the input value of <code>maxfil</code> is less than 0.
<code>ierr=-106</code>	The routine is interrupted because the size <code>n</code> of the input matrix is less than 0.
<code>ierr=-107</code>	The routine is interrupted, the error occurs: an element of the array <code>ja</code> is less than 0, or greater than <code>n</code> (see Sparse Matrix Storage Format section).
<code>ierr=101</code>	The value of <code>maxfil</code> is greater than or equal to <code>n</code> . The calculation is performed with the value of <code>maxfil</code> set to <code>(n-1)</code> .
<code>ierr=102</code>	The value of <code>tol</code> is less than 0. The calculation is performed with the value of the parameter set to <code>(-tol)</code>
<code>ierr=103</code>	The absolute value of <code>tol</code> is greater than value of <code>dpar(31)</code> ; it can result in instability of the calculation.
<code>ierr=104</code>	The value of <code>dpar(31)</code> is equal to 0. It can cause the fail of the calculations.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilut (n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
  INTEGER n, ierr, ipar(*), maxfil
  INTEGER ia(*), ja(*), ibilut(*), jbilut(*)
  DOUBLE PRECISION a(*), bilut(*), dpar(*), tol
```

C:

```
void dcsrilut (int *n, double *a, int *ia, int *ja, double *bilut, int *ibilut, int *jbilut,
  double *tol, int *maxfil, int *ipar, double *dpar, int *ierr);
```

Calling Sparse Solver and Preconditioner Routines from C/C++

The calling interface for all of the Intel MKL sparse solver and preconditioner routines is designed to be used easily from FORTRAN 77 or Fortran 90. However, any of these routines can be invoked directly from C or C++ if users are familiar with the inter-language calling conventions of their platforms. These conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from Fortran to C/C++, and the platform specific method of decoration for Fortran external names.

To promote portability, the C header files provide a set of macros and type definitions intended to hide the inter-language calling conventions and provide an interface to the Intel MKL sparse solver routines that appears natural for C/C++.

For example, consider a hypothetical library routine `foo` that takes a real vector of length `n`, and returns an integer status. Fortran users would access such a function as:

```
INTEGER n, status, foo
REAL x(*)
status = foo(x, n)
```

As noted above, to invoke `foo`, C users need to know what C data types correspond to Fortran types `INTEGER` and `REAL`; what argument passing mechanism the Fortran compiler uses; and what, if any, name decoration the Fortran compiler performs when generating the external symbol `foo`.

However, by using the C specific header file, for example `mkl_solver.h`, the invocation of `foo`, within a C program would look as follows:

```
#include "mkl_solver.h"

_INTEGER_t i, status;

_REAL_t x[];

status = foo( x, i );
```

Note that in the above example, the header file `mkl_solver.h` provides definitions for the types `_INTEGER_t` and `_REAL_t` that correspond to the Fortran types `INTEGER` and `REAL`.

To simplify calling of the Intel MKL sparse solver routines from C and C++, the following approach of providing C definitions of Fortran types is used: if an argument or a result from a sparse solver is documented as having the Fortran language specific type `XXX`, then the C and C++ header files provide an appropriate C language type definitions for the name `_XXX_t`.

Caveat for C Users

One of the key differences between C/C++ and Fortran is the argument passing mechanisms for the languages: Fortran programs use pass-by-reference semantics and C/C++ programs use pass-by-value semantics. In the above example, the header file `mkl_solver.h` attempts to hide this difference, by defining a macro `foo`, which takes the address of the appropriate arguments. For example, on the Tru64 UNIX* operating system `mkl_solver.h` defines the macro as follows:

```
#define foo(a,b) foo_(a, &(b))
```

Note how constants are treated when using the macro form of `foo`. `foo( x, 10 )` is converted into `foo_( x, &10 )`. In a strictly ANSI compliant C compiler, taking the address of a constant is not permitted, so a strictly conforming program would look like:

```
INTEGER_t iTen = 10;

_REAL_t * x;

status = foo( x, iTen );
```

However, some C compilers in a non-ANSI compliant mode enable taking the address of a constant for ease of use with Fortran programs. The form `foo( x, 10 )` is acceptable for such compilers.

Vector Mathematical Functions

This chapter describes Vector Mathematical Functions Library (VML), which is designed to compute mathematical functions on vector arguments. VML is an integral part of the Intel® MKL Kernel Library and the VML terminology is used here for simplicity in discussing this group of functions.

VML includes a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VML include nonlinear programming software, integrals computation, and many others.

VML functions are divided into the following groups according to the operations they perform:

- [VML Mathematical Functions](#) compute values of mathematical functions (such as sine, cosine, exponential, logarithm and so on) on vectors with unit increment indexing.
- [VML Pack/Unpack Functions](#) convert to and from vectors with positive increment indexing, vector indexing and mask indexing (see [Appendix B](#) for details on vector indexing methods).
- [VML Service Functions](#) allow the user to set/get the accuracy mode, and set/get the error code.

VML mathematical functions take an input vector as argument, compute values of the respective function element-wise, and return the results in an output vector.

Data Types and Accuracy Modes

Mathematical and pack/unpack vector functions in VML have been implemented for vector arguments of single and double precision real data. Both Fortran- and C-interfaces to all functions, including VML service functions, are provided in the library. The differences in naming and calling the functions for Fortran- and C-interfaces are detailed in the [Function Naming Conventions](#) section below.

Each vector function from VML (for each data format) can work in three modes: High Accuracy (HA), Low Accuracy (LA), and Enhanced Performance (EP). For many functions, using the LA version improves performance at the cost of slight reduction in accuracy (1-2 least significant bits). In contrast to the LA accuracy flavor, the EP flavor further enhances the performance at the cost of significant reduction in accuracy. In both single and double precision, about half bits of floating-point mantissa are correct. Moreover, subtle argument paths for certain functions (for example, large arguments in trigonometric functions) may be calculated with even less accuracy.

Despite the fact that default accuracy is HA, LA is more than sufficient in most cases. For certain applications that are not very demanding for accuracy (for example, media applications, some Monte Carlo simulations, etc.) you may find the EP accuracy flavor sufficient.

In addition, special value behavior may differ between the HA and LA versions of the functions. Any information on accuracy behavior can be found in the *Intel MKL Release Notes*.

Switching between the two modes (HA, LA, EP) is accomplished by using `vmlSetMode(mode)` (see [Table 9-14](#)). The function `vmlGetMode()` returns the currently used mode. The High Accuracy mode is used by default.

Function Naming Conventions

Full names of all VML functions include only lowercase letters for Fortran-interface, whereas for C-interface names the lowercase letters are mixed with uppercase.

VML mathematical and pack/unpack function full names have the following structure:

`v<p><name><mod>`

The initial letter `v` is a prefix indicating that a function belongs to VML.

The `<p>` field is a precision prefix that indicates the data type:

<code>s</code>	REAL for Fortran-interface, or <code>float</code> for C-interface
<code>d</code>	DOUBLE PRECISION for Fortran-interface, or <code>double</code> for C-interface.
<code>c</code>	COMPLEX for Fortran-interface, or <code>MKL_Complex8</code> for C-interface.
<code>z</code>	DOUBLE COMPLEX for Fortran-interface, or <code>MKL_Complex16</code> for C-interface.

The `<name>` field indicates the function short name, with some of its letters in uppercase for C-interface (see for example [Table 9-2](#) or [Table 9-13](#)).

The `<mod>` field (written in uppercase for C-interface) is present in pack/unpack functions only; it indicates the indexing method used:

<code>i</code>	indexing with positive increment
<code>v</code>	indexing with index vector
<code>m</code>	indexing with mask vector.

VML service function full names have the following structure:

`vml<name>`

where `vml` is a prefix indicating that a function belongs to VML, and `<name>` is the function short name, which includes some uppercase letters for C-interface (see [Table 9-13](#)). To call VML functions from an application program, use conventional function calls. For example, the VML exponential function for single precision real data can be called as

`call vsexp ( n, a, y )` for Fortran-interface, or

`vsExp ( n, a, y );` for C-interface.

Functions Interface

The interface to VML functions includes function full names and the arguments list. The Fortran- and C-interface descriptions for different groups of VML functions are given below. Note that some functions (`Div`, `Pow`, and `Atan2`) have two input vectors *a* and *b* as their arguments, while `SinCos` function has two output vectors *y* and *z*.

VML Mathematical Functions

Fortran:

```
call v<p><name>( n, a, y )
call v<p><name>( n, a, b, y )
call v<p><name>( n, a, y, z )
```

C:

```
v<p><name>( n, a, y );
v<p><name>( n, a, b, y );
v<p><name>( n, a, y, z );
```

Pack Functions

Fortran:

```
call v<p>packi( n, a, inca, y )
call v<p>packv( n, a, ia, y )
call v<p>packm( n, a, ma, y )
```

C:

```
v<p>PackI( n, a, inca, y );
v<p>PackV( n, a, ia, y );
v<p>PackM( n, a, ma, y );
```

Unpack Functions

Fortran:

```
call v<p>unpacki( n, a, y, incy )
call v<p>unpackv( n, a, y, iy )
call v<p>unpackm( n, a, y, my )
```

C:

```
v<p>UnpackI( n, a, y, incy );
v<p>UnpackV( n, a, y, iy );
v<p>UnpackM( n, a, y, my );
```

Service Functions

Fortran:

```
oldmode = vmlsetmode( mode )
mode = vmlgetmode( )
olderr = vmlseterrstatus ( err )
err = vmlgeterrstatus( )
olderr = vmlclearerrstatus( )
oldcallback = vmlseterrorcallback( callback )
callback = vmlgeterrorcallback( )
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus ( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlSetErrorCallBack( callback );
callback = vmlGetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Input Parameters

<i>n</i>	number of elements to be calculated
<i>a</i>	first input vector
<i>b</i>	second input vector

<i>inca</i>	vector increment for the input vector <i>a</i>
<i>ia</i>	index vector for the input vector <i>a</i>
<i>ma</i>	mask vector for the input vector <i>a</i>
<i>incy</i>	vector increment for the output vector <i>y</i>
<i>iy</i>	index vector for the output vector <i>y</i>
<i>my</i>	mask vector for the output vector <i>y</i>
<i>err</i>	error code
<i>mode</i>	VML mode
<i>callback</i>	address of the callback function

Output Parameters

<i>y</i>	first output vector
<i>z</i>	second output vector
<i>err</i>	error code
<i>mode</i>	VML mode
<i>olderr</i>	former error code
<i>oldmode</i>	former VML mode
<i>callback</i>	address of the callback function
<i>oldcallback</i>	address of the former callback function

The data types of the parameters used in each function are specified in the respective function description section. All VML mathematical functions can perform in-place operations, which means that the same vector can be used as both input and output parameter. This holds true for functions with two input vectors as well, in which case one of them may be overwritten with the output vector. For functions with two output vectors, one of them may coincide with the input vector. But partially overlapping input and output vectors could lead to unpredictable results.

Vector Indexing Methods

Current VML mathematical functions work only with unit increment. Arrays with other increments, or more complicated indexing, can be accommodated by gathering the elements into a contiguous vector and then scattering them after the computation is complete.

Three following indexing methods are used to gather/scatter the vector elements in VML:

- positive increment

- index vector
- mask vector.

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the *<mod>* field in [Function Naming Conventions](#)). For more information on indexing methods see [Vector Arguments in VML](#) in Appendix B.

Error Diagnostics

The VML library has its own error handler. The only difference for C- and Fortran- interfaces is that the Intel MKL error reporting routine `XERBLA` can be called after the Fortran- interface VML function encounters an error, and this routine gets information on `VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM` input errors (see [Table 9-16](#)).

The VML error handler has the following properties:

- The Error Status (`vmlErrStatus`) global variable is set after each VML function call. The possible values of this variable are shown in the [Table 9-16](#).
- Depending on the VML mode, the error handler function invokes:
 - `errno` variable setting. The possible values are shown in the [Table 9-1](#).
 - writing error text information to the `stderr` stream
 - raising the appropriate exception on error, if necessary
 - calling the additional error handler callback function.

Table 9-1. Set Values of the `errno` Variable

Value of <code>errno</code>	Description
0	No errors are detected.
<code>EINVAL</code>	The array dimension is not positive.
<code>EACCES</code>	NULL pointer is passed.
<code>EDOM</code>	At least one of array values is out of a range of definition.
<code>ERANGE</code>	At least one of array values caused a singularity, overflow or underflow.

VML Mathematical Functions

This section describes VML functions which compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function group is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data both for Fortran- and C-interfaces, as well as a description of the input/output arguments.

For all VML mathematical functions, the input range of parameters is equal to the mathematical range of definition in the set of defined values for the respective data type. Several VML functions, specifically `Div`, `Exp`, `Sinh`, `Cosh`, and `Pow`, can result in an overflow. For these functions, the respective input threshold values that mark off the precision overflow are specified in the function description section. Note that in these specifications, `FLT_MAX` denotes the maximum number representable in single precision real data type, while `DBL_MAX` denotes the maximum number representable in double precision real data type.

Table 9-2 lists available mathematical functions and data types associated with them.

Table 9-2. VML Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		
<code>Add</code>	<i>s, d, c, z</i>	Addition of the vector elements
<code>Sub</code>	<i>s, d, c, z</i>	Subtraction of the vector elements
<code>Sqr</code>	<i>s, d</i>	Squaring of the vector elements
<code>Mul</code>	<i>s, d, c, z</i>	Multiplication of the vector elements
<code>MulByConj</code>	<i>c, z</i>	Multiplication of elements of one vector by conjugated elements of the second vector
<code>Conj</code>	<i>c, z</i>	Conjugation of the vector elements
<code>Abs</code>	<i>s, d, c, z</i>	Absolute value of the vector elements
Power and Root Functions		
<code>Inv</code>	<i>s, d</i>	Inversion of the vector elements
<code>Div</code>	<i>s, d, c, z</i>	Divide elements of one vector by elements of second vector
<code>Sqrt</code>	<i>s, d, c, z</i>	Square root of vector elements
<code>InvSqrt</code>	<i>s, d</i>	Inverse square root of vector elements
<code>Cbrt</code>	<i>s, d</i>	Cube root of vector elements
<code>InvCbrt</code>	<i>s, d</i>	Inverse cube root of vector elements
<code>Pow2o3</code>	<i>s, d</i>	Each vector element raised to 2/3
<code>Pow3o2</code>	<i>s, d</i>	Each vector element raised to 3/2
<code>Pow</code>	<i>s, d, c, z</i>	Each vector element raised to the specified power
<code>Powx</code>	<i>s, d, c, z</i>	Each vector element raised to the constant power
<code>Hypot</code>	<i>s, d</i>	Square root of sum of squares
Exponential and Logarithmic Functions		
<code>Exp</code>	<i>s, d, c, z</i>	Exponential of vector elements
<code>Expml</code>	<i>s, d</i>	Exponential of vector elements decreased by 1
<code>Ln</code>	<i>s, d, c, z</i>	Natural logarithm of vector elements

Function	Data Types	Description
Logl0	<i>s, d, c, z</i>	Denary logarithm of vector elements
Loglp	<i>s, d</i>	Natural logarithm of vector elements that are increased by 1
Trigonometric Functions		
Cos	<i>s, d, c, z</i>	Cosine of vector elements
Sin	<i>s, d, c, z</i>	Sine of vector elements
SinCos	<i>s, d</i>	Sine and cosine of vector elements
CIS	<i>c, z</i>	Complex exponent of vector elements (cosine and sine combined to complex value)
Tan	<i>s, d, c, z</i>	Tangent of vector elements
Acos	<i>s, d, c, z</i>	Inverse cosine of vector elements
Asin	<i>s, d, c, z</i>	Inverse sine of vector elements
Atan	<i>s, d, c, z</i>	Inverse tangent of vector elements
Atan2	<i>s, d</i>	Four-quadrant inverse tangent of elements of two vectors
Hyperbolic Functions		
Cosh	<i>s, d, c, z</i>	Hyperbolic cosine of vector elements
Sinh	<i>s, d, c, z</i>	Hyperbolic sine of vector elements
Tanh	<i>s, d, c, z</i>	Hyperbolic tangent of vector elements
Acosh	<i>s, d, c, z</i>	Inverse hyperbolic cosine of vector elements
Asinh	<i>s, d, c, z</i>	Inverse hyperbolic sine of vector elements
Atanh	<i>s, d, c, z</i>	Inverse hyperbolic tangent of vector elements.
Special Functions		
Erf	<i>s, d</i>	Error function value of vector elements
Erfc	<i>s, d</i>	Complementary error function value of vector elements
ErfInv	<i>s, d</i>	Inverse error function value of vector elements
Rounding Functions		
Floor	<i>s, d</i>	Rounding towards minus infinity
Ceil	<i>s, d</i>	Rounding towards plus infinity
Trunc	<i>s, d</i>	Rounding towards zero infinity
Round	<i>s, d</i>	Rounding to nearest integer
NearbyInt	<i>s, d</i>	Rounding according to current mode
Rint	<i>s, d</i>	Rounding according to current mode and raising inexact result exception
Modf	<i>s, d</i>	Integer and fraction parts

Arithmetic Functions

Add

Performs element by element addition of vector a and vector b .

Syntax

Fortran:

```
call vsadd( n, a, b, y )
call vdadd( n, a, b, y )
call vcadd( n, a, b, y )
call vzadd( n, a, b, y )
```

C:

```
vsAdd( n, a, b, y );
vdAdd( n, a, b, y );
vcAdd( n, a, b, y );
vzAdd( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
a, b	FORTRAN: REAL, INTENT (IN) for vsadd DOUBLE PRECISION, INTENT (IN) for vdadd COMPLEX, INTENT (IN) for vcadd	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Name	Type	Description
	DOUBLE COMPLEX, INTENT(IN) for vzadd	
	C: const float* for vsAdd	
	const double* for vdAdd	
	const MKL_Complex8* for vcAdd	
	const MKL_Complex16* for vzAdd	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsadd DOUBLE PRECISION for vdadd COMPLEX, for vcadd DOUBLE COMPLEX for vzadd C: float* for vsAdd double* for vdAdd MKL_Complex8* for vcAdd MKL_Complex16* for vzAdd	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Sub

Performs element by element subtraction of vector *b* from vector *a*.

Syntax

Fortran:

```
call vssub( n, a, b, y )
call vdsb( n, a, b, y )
call vcsub( n, a, b, y )
call vzsub( n, a, b, y )
```

C:

```
vsSub( n, a, b, y );
vdSub( n, a, b, y );
vcSub( n, a, b, y );
vzSub( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN: REAL, INTENT (IN) for vssub DOUBLE PRECISION, INTENT (IN) for vdsb COMPLEX, INTENT (IN) for vcsub DOUBLE COMPLEX, INTENT (IN) for vzsub C: const float* for vsSub	FORTRAN: Arrays, specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
	const double* for vdSub	
	const MKL_Complex8* for vcSub	
	const MKL_Complex16* for vzSub	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vssub DOUBLE PRECISION for vdsusb COMPLEX, for vcsub DOUBLE COMPLEX for vzsub C: float* for vsSub double* for vdSub MKL_Complex8* for vcSub MKL_Complex16* for vzSub	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Sqr

Performs element by element squaring of the vector.

Syntax

Fortran:

```
call vssqr( n, a, y )
call vdsqr( n, a, y )
```

C:

```
vsSqr( n, a, y );
vdSqr( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
a	FORTTRAN: REAL, INTENT (IN) for vssqr DOUBLE PRECISION, INTENT (IN) for vdsqr C: const float* for vsSqr const double* for vdSqr	FORTTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y	FORTTRAN: REAL for vssqr DOUBLE PRECISION for vdsqr C: float* for vsSqr double* for vdSqr	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Mul

Performs element by element multiplication of vector a and vector b .

Syntax

Fortran:

```
call vsmul( n, a, b, y )
call vdmul( n, a, b, y )
call vcmul( n, a, b, y )
call vzmul( n, a, b, y )
```

C:

```
vsMul( n, a, b, y );
vdMul( n, a, b, y );
vcMul( n, a, b, y );
vzMul( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
a, b	FORTRAN: REAL, INTENT (IN) for vsmul DOUBLE PRECISION, INTENT (IN) for vdmul COMPLEX, INTENT (IN) for vcmul DOUBLE COMPLEX, INTENT (IN) for vzmul C: const float* for vsMul	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Name	Type	Description
	const double* for vdMul	
	const MKL_Complex8* for vcMul	
	const MKL_Complex16* for vzMul	

Output Parameters

Name	Type	Description
y	FORTTRAN: REAL for vsmul DOUBLE PRECISION for vdmul COMPLEX, for vcmul DOUBLE COMPLEX for vzmul C: float* for vsMul double* for vdMul MKL_Complex8* for vcMul MKL_Complex16* for vzMul	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

MulByConj

*Performs element by element multiplication of vector *a* element and conjugated vector *b* element.*

Syntax

Fortran:

```
call vcmulbyconj( n, a, b, y )  
call vzmulbyconj( n, a, b, y )
```

C:

```
vcMulByConj( n, a, b, y );  
vzMulByConj( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
a, b	FORTTRAN: COMPLEX, INTENT (IN) for vcmulbyconj DOUBLE COMPLEX, INTENT (IN) for vzmulbyconj C: const MKL_Complex8* for vcMulByConj const MKL_Complex16* for vzMulByConj	FORTTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Output Parameters

Name	Type	Description
y	FORTTRAN: COMPLEX, for vcmulbyconj DOUBLE COMPLEX for vzmulbyconj C: MKL_Complex8* for vcMulByConj MKL_Complex16* for vzMulByConj	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Conj

Performs element by element conjugation of the vector.

Syntax

Fortran:

```
call vcconj( n, a, y )
call vzconj( n, a, y )
```

C:

```
vcConj( n, a, y );
vzConj( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: COMPLEX, INTENT(IN) for vcconj DOUBLE COMPLEX, INTENT(IN) for vzconj C: const MKL_Complex8* for vcConj const MKL_Complex16* for vzConj	FORTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: COMPLEX, for <code>vcconj</code> DOUBLE COMPLEX for <code>vzconj</code> C: MKL_Complex8* for <code>vcConj</code> MKL_Complex16* for <code>vzConj</code>	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Abs

Computes absolute value of vector elements.

Syntax

Fortran:

```
call vsabs( n, a, y )
call vdabs( n, a, y )
call vcabs( n, a, y )
call vzabs( n, a, y )
```

C:

```
vsAbs( n, a, y );
vdAbs( n, a, y );
vcAbs( n, a, y );
vzAbs( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsabs DOUBLE PRECISION, INTENT (IN) for vdabs COMPLEX, INTENT (IN) for vcabs DOUBLE COMPLEX, INTENT (IN) for vzabs C: const float* for vsAbs const double* for vdAbs const MKL_Complex8* for vcAbs const MKL_Complex16* for vzAbs	FORTTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsabs, vcabs DOUBLE PRECISION for vdabs, vzabs C: float* for vsAbs, vcAbs double* for vdAbs, vzAbs	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Power and Root Functions

Inv

Performs element by element inversion of the vector.

Syntax

Fortran:

```
call vsinv( n, a, y )
call vdinv( n, a, y )
```

C:

```
vsInv( n, a, y );
vdInv( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsinv DOUBLE PRECISION, INTENT (IN) for vdinv C: const float* for vsInv const double* for vdInv	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsinv DOUBLE PRECISION for vdinv C: float* for vsInv double* for vdInv	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Div

Performs element by element division of vector a by vector b

Syntax

Fortran:

```
call vsdiv( n, a, b, y )  
call vddiv( n, a, b, y )  
call vcdiv( n, a, b, y )  
call vzdiv( n, a, b, y )
```

C:

```
vsDiv( n, a, b, y );  
vdDiv( n, a, b, y );  
vcDiv( n, a, b, y );  
vzDiv( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a, b</i>	FORTRAN: REAL, INTENT (IN) for vsdiv DOUBLE PRECISION, INTENT (IN) for vddiv COMPLEX, INTENT (IN) for vcdiv DOUBLE COMPLEX, INTENT (IN) for vzdiv C: const float* for vsDiv const double* for vdDiv const MKL_Complex8* for vcDiv const MKL_Complex16* for vzDiv	FORTRAN: Arrays, specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Table 9-3 Precision Overflow Thresholds for Div Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT\_MAX}$
double precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL\_MAX}$

NOTE. Overflow can occur also in Div complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vsdiv DOUBLE PRECISION for vddiv COMPLEX for vcdiv DOUBLE COMPLEX for vzdiv C: float* for vsDiv	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	double* for vdDiv	
	MKL_Complex8* for vcDiv	
	MKL_Complex16* for vzDiv	

Sqrt

Computes a square root of vector elements.

Syntax

Fortran:

```
call vssqrt( n, a, y )
call vdsqrt( n, a, y )
call vcsqrt( n, a, y )
call vzsqrt( n, a, y )
```

C:

```
vsSqrt( n, a, y );
vdSqrt( n, a, y );
vcSqrt( n, a, y );
vzSqrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for vssqrt DOUBLE PRECISION, INTENT(IN) for vdsqrt C: Pointer to an array that contains the input vector <i>a</i> .	FORTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	COMPLEX, INTENT(IN) for vcsqrt	
	DOUBLE COMPLEX, INTENT(IN) for vzsqrt	
	C: const float* for vsSqrt	
	const double* for vdSqrt	
	const MKL_Complex8* for vcSqrt	
	const MKL_Complex16* for vzSqrt	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vssqrt DOUBLE PRECISION for vdsqrt COMPLEX for vcsqrt DOUBLE COMPLEX for vzsqrt C: float* for vsSqrt double* for vdSqrt MKL_Complex8* for vcSqrt MKL_Complex16* for vzSqrt	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

InvSqrt

Computes an inverse square root of vector elements.

Syntax

Fortran:

```
call vsinvsqrt( n, a, y )
call vdinvsqrt( n, a, y )
```

C:

```
vsInvSqrt( n, a, y );
vdInvSqrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for vsinvsqrt DOUBLE PRECISION, INTENT(IN) for vdinvsqrt C: const float* for vsInvSqrt const double* for vdInvSqrt	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vsinvsqrt DOUBLE PRECISION for vdinvsqrt	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	C: float* for vsInvSqrt	
	double* for vdInvSqrt	

Cbrt

Computes a cube root of vector elements.

Syntax

Fortran:

```
call vscbrt( n, a, y )
call vdcbrt( n, a, y )
```

C:

```
vsCbrt( n, a, y );
vdCbrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vscbrt DOUBLE PRECISION, INTENT (IN) for vdcbrt C: const float* for vsCbrt const double* for vdCbrt	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for <code>vsqrt</code> DOUBLE PRECISION for <code>vdsqrt</code> C: <code>float*</code> for <code>vsqrt</code> <code>double*</code> for <code>vdsqrt</code>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

InvCbrt

Computes an inverse cube root of vector elements.

Syntax

Fortran:

```
call vsinvcbrrt( n, a, y )  
call vdsinvcbrrt( n, a, y )
```

C:

```
vsInvCbrrt( n, a, y );  
vdInvCbrrt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: <code>int</code>	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for <code>vsinvcbrrt</code> DOUBLE PRECISION, INTENT(IN) for <code>vdsinvcbrrt</code> C: <code>const float*</code> for <code>vsInvCbrrt</code>	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	<code>const double*</code> for <code>vdInvCbrt</code>	

Output Parameters

Name	Type	Description
<code>y</code>	FORTRAN: <code>REAL</code> for <code>vsinvcbtrt</code> <code>DOUBLE PRECISION</code> for <code>vdinvcbtrt</code> C: <code>float*</code> for <code>vsInvCbrt</code> <code>double*</code> for <code>vdInvCbrt</code>	FORTRAN: Array, specifies the output vector <code>y</code> . C: Pointer to an array that contains the output vector <code>y</code> .

Pow2o3

Raises each element of a vector to the constant power 2/3.

Syntax

Fortran:

```
call vspow2o3( n, a, y )
call vdpow2o3( n, a, y )
```

C:

```
vsPow2o3( n, a, y );
vdPow2o3( n, a, y );
```

Input Parameters

Name	Type	Description
<code>n</code>	FORTRAN: <code>INTEGER, INTENT (IN)</code> C: <code>int</code>	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a, b</i>	FORTRAN: REAL, INTENT (IN) for vspow2o3 DOUBLE PRECISION, INTENT (IN) for vdpow2o3 C: const float* for vsPow2o3 const double* for vdPow2o3	FORTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vspow2o3 DOUBLE PRECISION for vdpow2o3 C: float* for vsPow2o3 double* for vdPow2o3	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Pow3o2

Raises each element of a vector to the constant power 3/2.

Syntax

Fortran:

```
call vspow3o2( n, a, y )  
call vdpow3o2( n, a, y )
```

C:

```
vsPow3o2( n, a, y );  
vdPow3o2( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN: REAL, INTENT (IN) for vspow3o2 DOUBLE PRECISION, INTENT (IN) for vdpow3o2 C: const float* for vsPow3o2 const double* for vdPow3o2	FORTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Table 9-4 Precision Overflow Thresholds for Pow3o2 Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{2/3}$
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{2/3}$

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vspow3o2 DOUBLE PRECISION for vdpow3o2 C: float* for vsPow3o2 double* for vdPow3o2	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Pow

Computes a to the power b for elements of two vectors.

Syntax

Fortran:

```
call vspow( n, a, b, y )
call vdpow( n, a, b, y )
call vcpow( n, a, b, y )
call vzipow( n, a, b, y )
```

C:

```
vsPow( n, a, b, y );
vdPow( n, a, b, y );
vcPow( n, a, b, y );
vzPow( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
a, b	FORTRAN: REAL, INTENT (IN) for vspow DOUBLE PRECISION, INTENT (IN) for vdpow COMPLEX, INTENT (IN) for vcpow DOUBLE COMPLEX, INTENT (IN) for vzipow C: const float* for vsPow	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Name	Type	Description
	const double* for vdPow	
	const MKL_Complex8* for vcPow	
	const MKL_Complex16* for vzPow	

Table 9-5 Precision Overflow Thresholds for Pow Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{1/b[i]}$
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{1/b[i]}$

NOTE. Overflow can occur also in `Pow` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vspow DOUBLE PRECISION for vdpow COMPLEX for vcpow DOUBLE COMPLEX for vzpow C: float* for vsPow double* for vdPow MKL_Complex8* for vcPow MKL_Complex16* for vzPow	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The real function `Pow` has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a*[*i*] is positive, then *b*[*i*] may be arbitrary. For negative *a*[*i*], the value of *b*[*i*] must be integer (either positive or negative).

The complex function `POW` has no such input range limitations.

Powx

Raises each element of a vector to the constant power.

Syntax

Fortran:

```
call vspowx( n, a, b, y )
call vdpowx( n, a, b, y )
call vcpowx( n, a, b, y )
call vzipowx( n, a, b, y )
```

C:

```
vsPowx( n, a, b, y );
vdPowx( n, a, b, y );
vcPowx( n, a, b, y );
vzPowx( n, a, b, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vspowx DOUBLE PRECISION, INTENT (IN) for vdpowx COMPLEX, INTENT (IN) for vcpowx DOUBLE COMPLEX, INTENT (IN) for vzipowx	FORTTRAN: Array <i>a</i> that specifies the input vector C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	C: <code>const float*</code> for <code>vsPowx</code> <code>const double*</code> for <code>vdPowx</code> <code>const MKL_Complex8*</code> for <code>vcPowx</code> <code>const MKL_Complex16*</code> for <code>vzPowx</code>	
b	FORTTRAN: <code>REAL, INTENT (IN)</code> for <code>vspowx</code> <code>DOUBLE PRECISION, INTENT (IN)</code> for <code>vdpowx</code> <code>COMPLEX, INTENT (IN)</code> for <code>vcpowx</code> <code>DOUBLE COMPLEX, INTENT (IN)</code> for <code>vzpowx</code> C: <code>const float</code> for <code>vsPowx</code> <code>const double</code> for <code>vdPowx</code> <code>const MKL_Complex8*</code> for <code>vcPowx</code> <code>const MKL_Complex16*</code> for <code>vzPowx</code>	FORTTRAN: Scalar value b that is the constant power. C: Constant value for power b .

Table 9-6 Precision Overflow Thresholds for Powx Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{1/b}$
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{1/b}$

NOTE. Overflow can occur also in `Powx` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN: REAL for vspowx DOUBLE PRECISION for vdpowx COMPLEX for vcpowx DOUBLE COMPLEX for vzpowx C: float* for vsPowx double* for vdPowx MKL_Complex8* for vcPowx MKL_Complex16* for vzPowx	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The real function `Powx` has certain limitations on the input range of a and b parameters. Specifically, if $a[i]$ is positive, then b may be arbitrary. For negative $a[i]$, the value of b must be integer (either positive or negative).

The complex function `Powx` has no such input range limitations.

Hypot

Computes a square root of sum of two squared elements.

Syntax

Fortran:

```
call vshypot( n, a, b, y )  
call vdhypot( n, a, b, y )
```

C:

```
vsHypot( n, a, b, y );  
vdHypot( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of elements to be calculated.
a, b	FORTTRAN: REAL, INTENT (IN) for vshypot DOUBLE PRECISION, INTENT (IN) for vdhypot C: const float* for vsHypot const double* for vdHypot	FORTTRAN: Arrays that specify the input vectors a and b C: Pointers to arrays that contain the input vectors a and b .

Table 9-7 Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{sqrt}(\text{FLT\_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{FLT\_MAX})$
double precision	$\text{abs}(a[i]) < \text{sqrt}(\text{DBL\_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{DBL\_MAX})$

Output Parameters

Name	Type	Description
y	FORTTRAN: REAL for vshypot DOUBLE PRECISION for vdhypot C: float* for vsHypot double* for vdHypot	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Exponential and Logarithmic Functions

Exp

Computes an exponential of vector elements.

Syntax

Fortran:

```
call vsexp( n, a, y )
call vdexp( n, a, y )
call vcexp( n, a, y )
call vzexp( n, a, y )
```

C:

```
vsExp( n, a, y );
vdExp( n, a, y );
vcExp( n, a, y );
vzExp( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsexp DOUBLE PRECISION, INTENT (IN) for vdexp COMPLEX, INTENT (IN) for vcexp	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE COMPLEX, INTENT (IN) for vzexp	
	C: const float* for vsExp	
	const double* for vdExp	
	const MKL_Complex8* for vcExp	
	const MKL_Complex16* for vzExp	

Table 9-8 Precision Overflow Thresholds for Exp Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT\_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL\_MAX})$

NOTE. Overflow can occur also in `Exp` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsexp DOUBLE PRECISION for vdexp COMPLEX for vcexp DOUBLE COMPLEX for vzexp C: float* for vsExp double* for vdExp MKL_Complex8* for vcExp MKL_Complex16* for vzExp	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Expm1

Computes an exponential of vector elements decreased by 1.

Syntax

Fortran:

```
call vsexpm1( n, a, y )
call vdexpm1( n, a, y )
```

C:

```
vsExpm1( n, a, y );
vdExpm1( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsexpm1 DOUBLE PRECISION, INTENT (IN) for vdexpm1 C: const float* for vsExpm1 const double* for vdExpm1	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Table 9-9 Precision Overflow Thresholds for Expm1 Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT\_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL\_MAX})$

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsexpm1 DOUBLE PRECISION for vdexpm1 C: float* for vsExpml double* for vdExpml	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Ln

Computes natural logarithm of vector elements.

Syntax

Fortran:

```
call vsln( n, a, y )
call vdln( n, a, y )
call vcLn( n, a, y )
call vzln( n, a, y )
```

C:

```
vsLn( n, a, y );
vdLn( n, a, y );
vcLn( n, a, y );
vzLn( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsln	FORTTRAN: Array, specifies the input vector <i>a</i> .
	DOUBLE PRECISION, INTENT (IN) for vdl n	
	COMPLEX, INTENT (IN) for vcln	C: Pointer to an array that contains the input vector <i>a</i> .
	DOUBLE COMPLEX, INTENT (IN) for vzln	
	C: const float* for vsLn	
	const double* for vdLn	
	const MKL_Complex8* for vcLn	
	const MKL_Complex16* for vzLn	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsln	FORTTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdl n	
	COMPLEX for vcln	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for vzln	
	C: float* for vsLn	
	double* for vdLn	
	MKL_Complex8* for vcLn	
	MKL_Complex16* for vzLn	

Log10

Computes denary logarithm of vector elements.

Syntax

Fortran:

```
call vslog10( n, a, y )
call vdlog10( n, a, y )
call vclog10( n, a, y )
call vzlog10( n, a, y )
```

C:

```
vsLog10( n, a, y );
vdLog10( n, a, y );
vcLog10( n, a, y );
vzLog10( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for vslog10 DOUBLE PRECISION, INTENT(IN) for vdlog10 COMPLEX, INTENT(IN) for vclog10 DOUBLE COMPLEX, INTENT(IN) for vzlog10 C: const float* for vsLog10	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdLog10	
	const MKL_Complex8* for vcLog10	
	const MKL_Complex16* for vzLog10	

Output Parameters

Name	Type	Description
y	FORTTRAN: REAL for vslog10 DOUBLE PRECISION for vdlog10 COMPLEX for vclog10 DOUBLE COMPLEX for vzlog10 C: float* for vsLog10 double* for vdLog10 MKL_Complex8* for vcLog10 MKL_Complex16* for vzLog10	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Log1p

Computes natural logarithm of vector elements that are increased by 1.

Syntax

Fortran:

```
call vslog1p( n, a, y )  
call vdlog1p( n, a, y )
```

C:

```
vsLog1p( n, a, y );
```

```
vdLog1p( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vslog1p DOUBLE PRECISION, INTENT (IN) for vdlog1p C: const float* for vsLog1p const double* for vdLog1p	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vslog1p DOUBLE PRECISION for vdlog1p C: float* for vsLog1p double* for vdLog1p	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Trigonometric Functions

Cos

Computes cosine of vector elements.

Syntax

Fortran:

```
call vscos( n, a, y )
call vdcos( n, a, y )
call vccos( n, a, y )
call vzcoss( n, a, y )
```

C:

```
vsCos( n, a, y );
vdCos( n, a, y );
vcCos( n, a, y );
vzCos( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vscos DOUBLE PRECISION, INTENT (IN) for vdcos COMPLEX, INTENT (IN) for vccos	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vzcos	
	C: const float* for vsCos	
	const double* for vdCos	
	const MKL_Complex8* for vcCos	
	const MKL_Complex16* for vzCos	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vscos DOUBLE PRECISION for vdcos COMPLEX for vccos DOUBLE COMPLEX for vzcos C: float* for vsCos double* for vdCos MKL_Complex8* for vcCos MKL_Complex16* for vzCos	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML HA and LA functions. Alternatively, you can use VML EP functions that are fast on the entire function domain at the cost of accuracy.

Sin

Computes sine of vector elements.

Syntax

Fortran:

```
call vssin( n, a, y )
call vdsin( n, a, y )
call vcsin( n, a, y )
call vzsine( n, a, y )
```

C:

```
vsSin( n, a, y );
vdSin( n, a, y );
vcSin( n, a, y );
vzSin( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) . C: int.	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vssin DOUBLE PRECISION, INTENT (IN) for vdsin COMPLEX, INTENT (IN) for vcsin DOUBLE PRECISION, INTENT (IN) for vzsine C: const float* for vsSin	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdSin	
	const MKL_Complex8* for vcSin	
	const MKL_Complex16* for vzSin	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vssin DOUBLE PRECISION for vdsin COMPLEX for vcsin DOUBLE COMPLEX for vzsine C: float* for vsSin double* for vdSin MKL_Complex8* for vcSin MKL_Complex16* for vzSin	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML HA and LA functions. Alternatively, you can use VML EP functions that are fast on the entire function domain at the cost of accuracy.

SinCos

Computes sine and cosine of vector elements.

Syntax

Fortran:

```
call vssincos( n, a, y, z )
call vdsincos( n, a, y, z )
```

C:

```
vsSinCos( n, a, y, z );
vdSinCos( n, a, y, z );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) . C: int.	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vssincos DOUBLE PRECISION, INTENT (IN) for vdsincos C: const float* for vsSinCos const double* for vdSinCos	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y, z</i>	FORTTRAN: REAL for vssincos DOUBLE PRECISION for vdsincos C: float* for vsSinCos	FORTTRAN: Arrays, specify the output vectors <i>y</i> (for sine values) and <i>z</i> (for cosine values).

Name	Type	Description
	double* for vdSinCos	C: Pointers to arrays that contain the output vectors <i>y</i> (for sinevalues) and <i>z</i> (for cosine values).

Description

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML HA and LA functions. Alternatively, you can use VML EP functions that are fast on the entire function domain at the cost of accuracy.

CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

Fortran:

```
call vccis( n, a, y )
call vzcis( n, a, y )
```

C:

```
vcCIS( n, a, y );
vzCIS( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	FORTRAN: REAL, INTENT (IN) for <code>vccis</code> DOUBLE PRECISION, INTENT (IN) for <code>vzcis</code> C: <code>const float*</code> for <code>vcCIS</code> <code>const double*</code> for <code>vzCIS</code>	FORTRAN: Arrays, specify the input vector <i>a</i> . C: Pointers to arrays that contain the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: COMPLEX for <code>vccis</code> DOUBLE COMPLEX for <code>vzcis</code> C: <code>MKL_Complex8*</code> for <code>vcCIS</code> <code>MKL_Complex16*</code> for <code>vzCIS</code>	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Tan

Computes tangent of vector elements.

Syntax

Fortran:

```
call vstan( n, a, y )  
call vdtan( n, a, y )  
call vctan( n, a, y )  
call vztan( n, a, y )
```

C:

```
vsTan( n, a, y );
vdTan( n, a, y );
vcTan( n, a, y );
vzTan( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vstan DOUBLE PRECISION, INTENT (IN) for vdtan COMPLEX, INTENT (IN) for vctan DOUBLE COMPLEX, INTENT (IN) for vztan C: const float* for vsTan const double* for vdTan const MKL_Complex8* for vcTan const MKL_Complex16* for vzTan	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vstan DOUBLE PRECISION for vdtan COMPLEX for vctan	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	DOUBLE COMPLEX for vzTan	
	C: float* for vsTan	
	double* for vdTan	
	MKL_Complex8* for vcTan	
	MKL_Complex16* for vzTan	

Description

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trig function arguments for which VML provides the best possible performance. For performance reasons, avoid arguments that do not belong to the fast computational path in the VML HA and LA functions. Alternatively, you can use VML EP functions that are fast on the entire function domain at the cost of accuracy.

Acos

Computes inverse cosine of vector elements.

Syntax

Fortran:

```
call vsacos( n, a, y )
call vdacos( n, a, y )
call vcacos( n, a, y )
call vzacos( n, a, y )
```

C:

```
vsAcos( n, a, y );
vdAcos( n, a, y );
vcAcos( n, a, y );
vzAcos( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
a	FORTTRAN: REAL, INTENT (IN) for vsacos DOUBLE PRECISION, INTENT (IN) for vdacos COMPLEX, INTENT (IN) for vcacos DOUBLE COMPLEX, INTENT (IN) for vzaeos C: const float* for vsAcos const double* for vdAcos const MKL_Complex8* for vcAcos const MKL_Complex16* for vzAcos	FORTTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y	FORTTRAN: REAL for vsacos DOUBLE PRECISION for vdacos COMPLEX for vcacos DOUBLE COMPLEX for vzaeos C: float* for vsAcos double* for vdAcos MKL_Complex8* for vcAcos	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Name	Type	Description
	MKL_Complex16* for vzAcos	

Asin

Computes inverse sine of vector elements.

Syntax

Fortran:

```
call vsasin( n, a, y )
call vdasin( n, a, y )
call vcasin( n, a, y )
call vzasin( n, a, y )
```

C:

```
vsAsin( n, a, y );
vdAsin( n, a, y );
vcAsin( n, a, y );
vzAsin( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT(IN) for vsasin DOUBLE PRECISION, INTENT(IN) for vdasin COMPLEX, INTENT(IN) for vcasin	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE COMPLEX, INTENT(IN) for vzasin	
	C: const float* for vsAsin const double* for vdAsin const MKL_Complex8* for vcAsin const MKL_Complex16* for vzAsin	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsasin DOUBLE PRECISION for vdasin COMPLEX for vcasin DOUBLE COMPLEX for vzasin C: float* for vsAsin double* for vdAsin MKL_Complex8* for vcAsin MKL_Complex16* for vzAsin	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Atan

Computes inverse tangent of vector elements.

Syntax

Fortran:

```
call vsatan( n, a, y )
call vdatan( n, a, y )
call vcatan( n, a, y )
call vzatan( n, a, y )
```

C:

```
vsAtan( n, a, y );
vdAtan( n, a, y );
vcAtan( n, a, y );
vzAtan( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsatan DOUBLE PRECISION, INTENT (IN) for vdatan COMPLEX, INTENT (IN) for vcatan DOUBLE COMPLEX, INTENT (IN) for vzatan C: const float* for vsAtan const double* for vdAsin	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vcAtan	
	const MKL_Complex16* for vzAsin	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vsatan DOUBLE PRECISION for vdatan COMPLEX for vcatan DOUBLE COMPLEX for vzatan C: float* for vsAtan double* for vdAtan MKL_Complex8* for vcAtan MKL_Complex16* for vzAtan	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Fortran:

```
call vsatan2( n, a, b, y )
call vdatan2( n, a, b, y )
```

C:

```
vsAtan2( n, a, b, y );
vdAtan2( n, a, b, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
a, b	FORTRAN: REAL, INTENT(IN) for vsatan2 DOUBLE PRECISION, INTENT(IN) for vdatan2 C: const float* for vsAtan2 const double* for vdAtan2	FORTRAN: Arrays, specify the input vectors a and b . C: Pointers to arrays that contain the input vectors a and b .

Output Parameters

Name	Type	Description
y	FORTRAN: REAL for vsatan2 DOUBLE PRECISION for vdatan2 C: float* for vsAtan2 double* for vdAtan2	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The elements of the output vector y are computed as the four-quadrant arctangent of $a[i]/b[i]$.

Hyperbolic Functions

Cosh

Computes hyperbolic cosine of vector elements.

Syntax

Fortran:

```
call vscosh( n, a, y )
call vdcosh( n, a, y )
call vccosh( n, a, y )
call vzcosh( n, a, y )
```

C:

```
vsCosh( n, a, y );
vdCosh( n, a, y );
vcCosh( n, a, y );
vzCosh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vscosh DOUBLE PRECISION, INTENT (IN) for vdcosh COMPLEX, INTENT (IN) for vccosh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE COMPLEX, INTENT(IN) for vzcosh	
	C: const float* for vsCosh	
	const double* for vdCosh	
	const MKL_Complex8* for vcCosh	
	const MKL_Complex16* for vzCosh	

Table 9-10 Precision Overflow Thresholds for Cosh Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT\_MAX}) - \ln 2 < a[i] < \ln(\text{FLT\_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL\_MAX}) - \ln 2 < a[i] < \ln(\text{DBL\_MAX}) + \ln 2$

NOTE. Overflow can occur also in Cosh complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vscosh DOUBLE PRECISION for vdcosh COMPLEX for vccosh DOUBLE COMPLEX for vzcosh C: float* for vsCosh double* for vdCosh MKL_Complex8* for vcCosh MKL_Complex16* for vzCosh	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Sinh

Computes hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vssinh( n, a, y )
call vdsinh( n, a, y )
call vcsinh( n, a, y )
call vzsinh( n, a, y )
```

C:

```
vsSinh( n, a, y );
vdSinh( n, a, y );
vcSinh( n, a, y );
vzSinh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for vssinh DOUBLE PRECISION, INTENT(IN) for vdsinh COMPLEX, INTENT(IN) for vcsinh DOUBLE COMPLEX, INTENT(IN) for vzsinh C: const float* for vsSinh const double* for vdSinh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vcSinh	
	const MKL_Complex16* for vzSinh	

Table 9-11 Precision Overflow Thresholds for Sinh Real Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT\_MAX}) - \ln 2 < a[i] < \ln(\text{FLT\_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL\_MAX}) - \ln 2 < a[i] < \ln(\text{DBL\_MAX}) + \ln 2$

NOTE. Overflow can occur also in `Sinh` complex function, but the exact formula is beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTTRAN: REAL for vssinh DOUBLE PRECISION for vdsinh COMPLEX for vcsinh DOUBLE COMPLEX for vzsinh C: float* for vsSinh double* for vdSinh MKL_Complex8* for vcSinh MKL_Complex16* for vzSinh	FORTTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Tanh

Computes hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vstanh( n, a, y )
call vdtanh( n, a, y )
call vctanh( n, a, y )
call vztanh( n, a, y )
```

C:

```
vsTanh( n, a, y );
vdTanh( n, a, y );
vcTanh( n, a, y );
vzTanh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vstanh DOUBLE PRECISION, INTENT (IN) for vdtanh COMPLEX, INTENT (IN) for vctanh DOUBLE COMPLEX, INTENT (IN) for vztanh C: const float* for vsTanh const double* for vdTanh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex8* for vcTanh	
	const MKL_Complex16* for vzTanh	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vstanh DOUBLE PRECISION for vdtanh COMPLEX for cstanh DOUBLE COMPLEX for zdtanh C: float* for vsTanh double* for vdTanh MKL_Complex8* for vcTanh MKL_Complex16* for vzTanh	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

Fortran:

```
call vsacosh( n, a, y )  
call vdacosh( n, a, y )  
call vcacosh( n, a, y )  
call vzacosh( n, a, y )
```

C:

`vsAcosh( n, a, y );`

`vdAcosh( n, a, y );`

`vcAcosh( n, a, y );`

`vzAcosh( n, a, y );`

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for <code>vsacosh</code> DOUBLE PRECISION, INTENT (IN) for <code>vdacosh</code> COMPLEX, INTENT (IN) for <code>vcacosh</code> DOUBLE COMPLEX, INTENT (IN) for <code>vzacosh</code> C: const float* for <code>vsAcosh</code> const double* for <code>vdAcosh</code> const MKL_Complex8* for <code>vcAcosh</code> const MKL_Complex16* for <code>vzAcosh</code>	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for <code>vsacosh</code> DOUBLE PRECISION for <code>vdacosh</code>	FORTTRAN: Array, specifies the output vector <i>y</i> .

Name	Type	Description
	COMPLEX for <code>vcacosh</code>	C: Pointer to an array that contains the output vector <i>y</i> .
	DOUBLE COMPLEX for <code>vzacosh</code>	
	C: float* for <code>vsAcosh</code>	
	double* for <code>vdAcosh</code>	
	MKL_Complex8* for <code>vcAcosh</code>	
	MKL_Complex16* for <code>vzAcosh</code>	

Asinh

Computes inverse hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vsasinh( n, a, y )
call vdasinh( n, a, y )
call vcasinh( n, a, y )
call vzasinh( n, a, y )
```

C:

```
vsAsinh( n, a, y );
vdAsinh( n, a, y );
vcAsinh( n, a, y );
vzAsinh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsasinh DOUBLE PRECISION, INTENT (IN) for vdasinh COMPLEX, INTENT (IN) for vcasinh DOUBLE COMPLEX, INTENT (IN) for vzasinh C: const float* for vsAsinh const double* for vdAsinh const MKL_Complex8* for vcAsinh const MKL_Complex16* for vzAsinh	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsasinh DOUBLE PRECISION for vdasinh COMPLEX for vcasinh DOUBLE COMPLEX for vzasinh C: float* for vsAsinh double* for vdAsinh MKL_Complex8* for vcAsinh MKL_Complex16* for vzAsinh	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Atanh

Computes inverse hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vsatanh( n, a, y )
call vdatanh( n, a, y )
call vcatanh( n, a, y )
call vzatanh( n, a, y )
```

C:

```
vsAtanh( n, a, y );
vdAtanh( n, a, y );
vcAtanh( n, a, y );
vzAtanh( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsatanh DOUBLE PRECISION, INTENT (IN) for vdatanh COMPLEX, INTENT (IN) for vcatanh DOUBLE COMPLEX, INTENT (IN) for vzatanh C: const float* for vsAtanh	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const double* for vdAtanh	
	const MKL_Complex8* for vcAtanh	
	const MKL_Complex16* for vzAtanh	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsatanh DOUBLE PRECISION for vdatanh COMPLEX for vcatanh DOUBLE COMPLEX for vzatanh C: float* for vsAtanh double* for vdAtanh MKL_Complex8* for vcAtanh MKL_Complex16* for vzAtanh	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Special Functions

Erf

Computes the error function value of vector elements.

Syntax

Fortran:

```
call vserf( n, a, y )
call vderf( n, a, y )
```

C:

```
vsErf( n, a, y );
```

```
vdErf( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vserf DOUBLE PRECISION, INTENT (IN) for vderf C: const float* for vsErf const double* for vdErf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vserf DOUBLE PRECISION for vderf C: float* for vsErf double* for vdErf	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function `Erf` computes the error function values for elements of the input vector *a* and writes them to the output vector *y*.

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x) ,$

where erfc is the complementary error function.

2. $\Phi(x) = \frac{1}{2} \text{erf} (x/\sqrt{2}) ,$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp (- t^2/2) dt$$

is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1) ,$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

Erfc

Computes the complementary error function value of vector elements.

Syntax

Fortran:

```
call vserfc( n, a, y )
```

```
call vderfc( n, a, y )
```

C:

```
vsErfc( n, a, y );
```

```
vdErfc( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vserfc DOUBLE PRECISION, INTENT (IN) for vderfc C: const float* for vsErfc const double* for vdErfc	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vserfc DOUBLE PRECISION for vderfc C: float* for vsErfc double* for vdErfc	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function `Erfc` computes the complementary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The complementary error function is defined as given by:

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

1. $\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$.

2. $\Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2})$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1)$,

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

ErfInv

Computes inverse error function value of vector elements.

Syntax

Fortran:

```
call vserfinv( n, a, y )
call vderfinv( n, a, y )
```

C:

```
vsErfInv( n, a, y );
vdErfInv( n, a, y );
```

Input Parameters

Name	Type	Description
n	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
a	FORTRAN: REAL, INTENT(IN) for vserfinv DOUBLE PRECISION, INTENT(IN) for vderfinv C: const float* for vsErfInv const double* for vdErfInv	FORTRAN: Array, specifies the input vector a . C: Pointer to an array that contains the input vector a .

Output Parameters

Name	Type	Description
y	FORTRAN: REAL for vserfinv DOUBLE PRECISION for vderfinv C: float* for vsErfInv double* for vdErfInv	FORTRAN: Array, specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The function `ErfInv` computes the inverse error function values for elements of the input vector a and writes them to the output vector y

$$y = \operatorname{erf}^{-1}(a),$$

where $\operatorname{erf}(x)$ is the error function defined as given by:

$$\operatorname{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

$$1. \operatorname{erf}^{-1}(x) = \operatorname{erfc}^{-1}(1 - x),$$

where `erfc` is the complementary error function.

$$2. \Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

Rounding Functions

Floor

Computes a rounded towards minus infinity integer value for each vector element.

Syntax

Fortran:

```
call vsfloor( n, a, y )
```

```
call vdfloor( n, a, y )
```

C:

```
vsFloor( n, a, y );
```

```
vdFloor( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT(IN) for vsfloor DOUBLE PRECISION, INTENT(IN) for vdfloor C: const float* for vsFloor const double* for vdFloor	FORTTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsfloor DOUBLE PRECISION for vdfloor C: float* for vsFloor double* for vdFloor	FORTTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Ceil

Computes a rounded towards plus infinity integer value for each vector element.

Syntax

Fortran:

```
call vsceil( n, a, y )  
call vdceil( n, a, y )
```

C:

```
vsCeil( n, a, y );
```

```
vdCeil( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsceil DOUBLE PRECISION, INTENT (IN) for vdceil C: const float* for vsCeil const double* for vdCeil	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vsceil DOUBLE PRECISION for vdceil C: float* for vsCeil double* for vdCeil	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Trunc

Computes a rounded towards zero integer value for each vector element.

Syntax

Fortran:

```
call vstrunc( n, a, y )
call vdtrunc( n, a, y )
```

C:

```
vsTrunc( n, a, y );
vdTrunc( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for vstrunc DOUBLE PRECISION, INTENT(IN) for vdtrunc C: const float* for vsTrunc const double* for vdTrunc	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vstrunc DOUBLE PRECISION for vdtrunc C: float* for vsTrunc	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	double* for vdTrunc	

Round

Computes a rounded to nearest integer value for each vector element.

Syntax

Fortran:

```
call vsround( n, a, y )
call vdround( n, a, y )
```

C:

```
vsRound( n, a, y );
vdRound( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsround DOUBLE PRECISION, INTENT (IN) for vdround C: const float* for vsRound const double* for vdRound	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vsround DOUBLE PRECISION for vdround C: float* for vsRound double* for vdRound	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

Halfway values, that is, 0.5, -1.5, and the like, are rounded off away from zero. That is, 0.5 -> 1, -1.5 -> -2, etc.

NearbyInt

Computes a rounded integer value in a current rounding mode for each vector element.

Syntax

Fortran:

```
call vsnearbyint( n, a, y )
```

```
call vdnearbyint( n, a, y )
```

C:

```
vsNearbyInt( n, a, y );
```

```
vdNearbyInt( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT(IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT(IN) for vsnearbyint	FORTRAN: Array, specifies the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdnearbyint	C: Pointer to an array that contains the input vector <i>a</i> .
	C: const float* for vsNearbyInt	
	const double* for vdNearbyInt	

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vsnearbyint	FORTTRAN: Array, specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdnearbyint	C: Pointer to an array that contains the output vector <i>y</i> .
	C: float* for vsNearbyInt	
	double* for vdNearbyInt	

Description

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values.

Rint

Computes a rounded integer value in a current rounding mode for each vector element with inexact result exception raised for each changed value.

Syntax

Fortran:

```
call vsrint( n, a, y )
call vdrint( n, a, y )
```

C:

```
vsRint( n, a, y );  
vdRint( n, a, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsrint DOUBLE PRECISION, INTENT (IN) for vdrint C: const float* for vsRint const double* for vdRint	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN: REAL for vsrint DOUBLE PRECISION for vdrint C: float* for vsRint double* for vdRint	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values. For each changed value, inexact result exception is raised.

Modf

Computes a truncated integer value and remaining fraction part for each vector element.

Syntax

Fortran:

```
call vsmodf( n, a, y, z )
call vdmodf( n, a, y, z )
```

C:

```
vsModf( n, a, y, z );
vdModf( n, a, y, z );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsmodf DOUBLE PRECISION, INTENT (IN) for vdmodf C: const float* for vsModf const double* for vdModf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Output Parameters

Name	Type	Description
<i>y, z</i>	FORTRAN: REAL for vsmodf DOUBLE PRECISION for vdmodf C: float* for vsModf	FORTRAN: Array, specifies the output vector <i>y</i> and <i>z</i> . C: Pointer to an array that contains the output vector <i>y</i> and <i>z</i> .

Name	Type	Description
	double* for vdModf	

VML Pack/Unpack Functions

This section describes VML functions which convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing and mask indexing (see [Appendix B](#) for details on vector indexing methods).

[Table 9-12](#) lists available VML Pack/Unpack functions, together with data types and indexing methods associated with them.

Table 9-12 VML Pack/Unpack Functions

Function	Short Name	Data Types	Indexing Methods	Description
Pack		s, d	I, V, M	Gathers elements of arrays, indexed by different methods.
Unpack		s, d	I, V, M	Scatters vector elements to arrays with different indexing.

Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

Fortran:

```
call vsPackI( n, a, inca, y )
call vsPackV( n, a, ia, y )
call vsPackM( n, a, ma, y )
call vdPackI( n, a, inca, y )
call vdPackV( n, a, ia, y )
call vdPackM( n, a, ma, y )
```

C:

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN). C: int.	Specifies the number of elements to be calculated.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vspacki, vspackv, vspackm DOUBLE PRECISION, INTENT (IN) for vdpacki, vdpackv, vdpackm. C: const float* for vsPackI, vsPackV, vsPackM const double* for vdPackI, vdPackV, vdPackM	FORTTRAN: Array, DIMENSION at least (1 + (n-1)*inca) for vspacki/vdpacki, Array, DIMENSION at least max (n,max(ia[j])), j=0, ..., n-1 for vspackv/vdpackv , Array, DIMENSION at least n for vspackm/vdpackm. Specifies the input vector <i>a</i> . C: Specifies pointer to an array that contains the input vector <i>a</i> . Size of the array must be: at least (1 + (n-1)*inca) for vsPackI/vdPackI, at least max(n,max(ia[j])), j=0, ..., n-1 for vsPackV/vdPackV , at least n for vsPackM/vdPackM.

Name	Type	Description
<i>inca</i>	FORTTRAN: INTEGER, INTENT (IN) for vspacki, vdpacki. C: int for vsPackI, vdPackI.	Specifies the increment for the elements of <i>a</i> .
<i>ia</i>	FORTTRAN: INTEGER, INTENT (IN) for vspackv, vdpackv. C: const int* for vsPackV, vdPackV.	FORTTRAN: Array, DIMENSION at least <i>n</i> . Specifies the index vector for the elements of <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i> .
<i>ma</i>	FORTTRAN: INTEGER, INTENT (IN) for vspackm, vdpackm. C: const int* for vsPackM, vdPackM.	FORTTRAN: Array, DIMENSION at least <i>n</i> , Specifies the mask vector for the elements of <i>a</i> . C: Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	FORTTRAN: REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm. C: float* for vsPackI, vsPackV, vsPackM double* for vdPackI, vdPackV, vdPackM	FORTTRAN: Array, DIMENSION at least <i>n</i> . Specifies the output vector <i>y</i> . C: Pointer to an array of size at least <i>n</i> that contains the output vector <i>y</i> .

Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

Fortran:

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
```

C:

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN). C: int.	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsunpacki, vsunpackv, vsunpackm	FORTRAN: Array, DIMENSION at least <i>n</i> . Specifies the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdunpacki, vdunpackv, vdunpackm. C: const float* for vsUnpackI, vsUnpackV, vsUnpackM const double* for vdUnpackI, vdUnpackV, vdUnpackM	C: Specifies the pointer to an array of size at least n that contains the input vector a .
<i>incy</i>	FORTRAN: INTEGER, INTENT(IN) for vsunpacki, vdunpacki. C: int for vsUnpackI, vdUnpackI.	Specifies the increment for the elements of y .
<i>iy</i>	FORTRAN: INTEGER, INTENT(IN) for vsunpackv, vdunpackv. C: const int* for vsUnpackV, vdUnpackV.	FORTRAN: Array, DIMENSION at least n . Specifies the index vector for the elements of y . C: Specifies the pointer to an array of size at least n that contains the index vector for the elements of a .
<i>my</i>	FORTRAN: INTEGER, INTENT(IN) for vsunpackm, vdunpackm. C: const int* for vsUnpackM, vdUnpackM.	FORTRAN: Array, DIMENSION at least n , Specifies the mask vector for the elements of y . C: Specifies the pointer to an array of size at least n that contains the mask vector for the elements of a .

Output Parameters

Name	Type	Description
y	FORTRAN: REAL for vsunpacki, vsunpackv, vsunpackm	FORTRAN: Array, DIMENSION at least $(1 + (n-1)*incy)$ for vsunpacki,

Name	Type	Description
	DOUBLE PRECISION for vdunpacki, vdunpackv, vdunpackm.	at least $\max(n, \max(iy[j]))$, $j=0, \dots, n-1$, for vsunpackv, at least n for vsunpackm/vdunpackm
	C: float* for vsUnpackI, vsUnpackV, vsUnpackM double* for vdUnpackI, vdUnpackV, vdUnpackM	C: Specifies the pointer to an array that contains the output vector y . Size of the array must be: at least $(1 + (n-1)*incy)$ for vsUnPackI, at least $\max(n, \max(ia[j]))$, $j=0, \dots, n-1$, for vsUnPackV, at least n for vsUnPackM.

VML Service Functions

VML Service functions allow the user to set /get the accuracy mode, and set/get the error code. All these functions are available both in Fortran- and C- interfaces. [Table 9-13](#) lists available VML Service functions and their short description.

Table 9-13 VML Service Functions

Function Short Name	Description
SetMode	Sets the VML mode
GetMode	Gets the VML mode
SetErrStatus	Sets the VML error status
GetErrStatus	Gets the VML error status
ClearErrStatus	Clears the VML error status
SetErrorCallBack	Sets the additional error handler callback function
GetErrorCallBack	Gets the additional error handler callback function
ClearErrorCallBack	Deletes the additional error handler callback function

SetMode

Sets a new mode for VML functions according to *mode* parameter and stores the previous VML mode to *oldmode*.

Syntax

Fortran:

```
oldmode = vmlsetmode( mode )
```

C:

```
oldmode = vmlSetMode( mode );
```

Input Parameters

Name	Type	Description
<i>mode</i>	FORTTRAN: INTEGER, INTENT(IN) C: int	Specifies the VML mode to be set.

Output Parameters

Name	Type	Description
<i>oldmode</i>	FORTTRAN: INTEGER C: int	Specifies the former VML mode.

Description

The *mode* parameter is designed to control accuracy, FPU, error handling and threading options. [Table 9-14](#) lists values of the *mode* parameter. All other possible values of the *mode* parameter may be obtained from these values by using bitwise OR (|) operation to combine one value for accuracy, one for FPU, and one for error control options. The default value of the *mode* parameter is `VML_HA | VML_ERRMODE_DEFAULT | VML_NUM_THREADES_OMP_AUTO`. Thus, the current FPU control word (FPU precision and the rounding method) is used by default.

If any VML mathematical function requires different FPU precision, or rounding method, it changes these options automatically and then restores the former values. The *mode* parameter enables you to minimize switching the internal FPU mode inside each VML mathematical function

that works with similar precision and accuracy settings. To accomplish this, set the *mode* parameter to `VML_FLOAT_CONSISTENT` for single precision real and complex functions, or to `VML_DOUBLE_CONSISTENT` for double precision real and complex functions. These values of the *mode* parameter are the optimal choice for the respective function groups, as they are required for most of the VML mathematical functions. After the execution is over, set the *mode* to `VML_RESTORE` if you need to restore the previous FPU mode.

Table 9-14 Values of the *mode* Parameter

Value of <i>mode</i>	Description
Accuracy Control	
<code>VML_HA</code>	High accuracy versions of VML functions will be used.
<code>VML_LA</code>	Low accuracy versions of VML functions will be used.
<code>VML_EP</code>	Enhanced Performance accuracy versions of VML functions will be used.
Additional FPU Mode Control	
<code>VML_FLOAT_CONSISTENT</code>	The optimal FPU mode (control word) for single precision functions is set, and the previous FPU mode is saved.
<code>VML_DOUBLE_CONSISTENT</code>	The optimal FPU mode (control word) for double precision functions is set, and the previous FPU mode is saved.
<code>VML_RESTORE</code>	The previously saved FPU mode is restored.
Error Mode Control	
<code>VML_ERRMODE_IGNORE</code>	No action is set for computation errors.
<code>VML_ERRMODE_ERRNO</code>	On error, the <i>errno</i> variable is set.
<code>VML_ERRMODE_STDERR</code>	On error, the error text information is written to <i>stderr</i> .
<code>VML_ERRMODE_EXCEPT</code>	On error, an exception is raised.
<code>VML_ERRMODE_CALLBACK</code>	On error, an additional error handler function is called.
<code>VML_ERRMODE_DEFAULT</code>	On error, the <i>errno</i> variable is set, an exception is raised, and an additional error handler function is called.
Treading Mode Control	
<code>VML_NUM_THREADS_OMP_AUTO</code>	This is default behavior. Maximum number of threads is determined by environmental variable <code>OMP_NUM_THREADS</code> and can be overridden by OpenMP* function <code>omp_set_num_threads()</code> . For performance reasons VML threading logic can use fewer number of threads.

Value of <i>mode</i>	Description
VML_NUM_THREADS_OMP_FIXED	Number of threads is determined by environmental variable OMP_NUM_THREADS and can be overridden by OpenMP* function <code>omp_set_num_threads()</code> . Use this mode to disable VML threading logic.

Examples

Several examples of calling the function `vmlSetMode()` with different values of the *mode* parameter are given below:

Fortran:

```
oldmode = vmlsetmode( VML_LA )  
  
call vmlsetmode( IOR(VML_LA, IOR(VML_FLOAT_CONSISTENT,  
VML_ERRMODE_IGNORE )))  
  
call vmlsetmode( VML_RESTORE)  
  
call vmlsetmode( VML_NUM_THREADS_OMP_FIXED)
```

C:

```
vmlSetMode( VML_LA );  
  
vmlSetMode( VML_LA | VML_FLOAT_CONSISTENT | VML_ERRMODE_IGNORE );  
  
vmlSetMode( VML_RESTORE);  
  
vmlSetMode( VML_NUM_THREADS_OMP_FIXED);
```

GetMode

Gets the VML mode.

Syntax

Fortran:

```
mod = vmlgetmode()
```

C:

```
mod = vmlGetMode( void );
```

Output Parameters

Name	Type	Description
<i>mod</i>	FORTTRAN: INTEGER C: int	Specifies the packed <i>mode</i> parameter.

Description

The function `vmlGetMode()` returns the VML *mode* parameter that controls accuracy, FPU, and error handling options. The *mod* variable value is some combination of the values listed in the [Table 9-14](#). You can obtain some of these values using the respective mask from the [Table 9-15](#).

Table 9-15 Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy <i>mode</i> selection.
VML_FPUMODE_MASK	Specifies mask for FPU <i>mode</i> selection.
VML_ERRMODE_MASK	Specifies mask for error <i>mode</i> selection.

See example below:

Examples

Fortran:

```
mod = vmlgetmode()
accm = IAND(mod, VML_ACCURACY_MASK)
fpum = IAND(mod, VML_FPUMODE_MASK)
errm = IAND(mod, VML_ERRMODE_MASK)
```

C:

```
accm = vmlGetMode(void ) & VML_ACCURACY_MASK;
fpum = vmlGetMode(void ) & VML_FPUMODE_MASK;
errm = vmlGetMode(void ) & VML_ERRMODE_MASK;
```

SetErrStatus

Sets the new VML error status according to *err* and stores the previous VML error status to *olderr*.

Syntax

Fortran:

```
olderr = vmlseterrstatus( err )
```

C:

```
olderr = vmlSetErrStatus( err );
```

Input Parameters

Name	Type	Description
<i>err</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Specifies the VML error status to be set.

Output Parameters

Name	Type	Description
<i>olderr</i>	FORTTRAN: INTEGER C: int	Specifies the former VML error status.

Description

Table 9-16 lists possible values of the *err* parameter.

Table 9-16 Values of the VML Error Status

Error Status	Description
VML_STATUS_OK	The execution was completed successfully.
VML_STATUS_BADSIZE	The array dimension is not positive.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of array values caused a singularity.

Error Status	Description
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
vmlSetErrStatus( VML_STATUS_OK );
vmlSetErrStatus( VML_STATUS_ERRDOM );
vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

GetErrStatus

Gets the VML error status.

Syntax

Fortran:

```
err = vmlgeterrstatus( )
```

C:

```
err = vmlGetErrStatus( void );
```

Output Parameters

Name	Type	Description
<i>err</i>	FORTTRAN: INTEGER C: int	Specifies the VML error status.

ClearErrStatus

Sets the VML error status to `VML_STATUS_OK` and stores the previous VML error status to `olderr`.

Syntax

Fortran:

```
olderr = vmlclearerrstatus( )
```

C:

```
olderr = vmlClearErrStatus( void );
```

Output Parameters

Name	Type	Description
<code>olderr</code>	FORTTRAN: INTEGER C: int	Specifies the former VML error status.

SetErrorCallBack

Sets the additional error handler callback function and gets the old callback function.

Syntax

Fortran:

```
oldcallback = vmlseterrorcallback( callback )
```

C:

```
oldcallback = vmlSetErrorCallBack( callback );
```

Input Parameters

Name	Description
FORTTRAN: Address of the callback function. <i>callback</i>	The callback function has the following format: <pre> INTEGER FUNCTION ERRFUNC(par) TYPE (ERROR_STRUCTURE) par ! ... ! user error processing ! ... ERRFUNC = 0 ! if ERRFUNC= 0 - standard VML error handler ! is called after the callback ! if ERRFUNC != 0 - standard VML error handler ! is not called END </pre> The passed error structure is defined as follows: <pre> TYPE ERROR_STRUCTURE SEQUENCE INTEGER*4 ICODE INTEGER*4 IINDEX REAL*8 DBA1 REAL*8 DBA2 REAL*8 DBR1 REAL*8 DBR2 CHARACTER(64) CFUNCNAME INTEGER*4 IFUNCNAMELEN END TYPE ERROR_STRUCTURE </pre>

Name	Description
C: <i>callback</i> Pointer to the callback function.	The callback function has the following format: <pre data-bbox="867 392 1235 623">static int __stdcall MyHandler(DefVmlErrorContext* pContext) { /* Handler body */ };</pre> The passed error structure is defined as follows: <pre data-bbox="867 722 1360 1362">typedef struct _DefVmlErrorContext { int iCode; /* Error status value */ int iIndex; /* Index for bad array element, or bad array dimension, or bad array pointer */ double dbA1; /* Error argument 1 */ double dbA2; /* Error argument 2 */ double dbR1; /* Error result 1 */ double dbR2; /* Error result 2 */ char cFuncName[64]; /* Function name */ int iFuncNameLen; /* Length of functionname*/ } DefVmlErrorContext;</pre>

Output Parameters

Name	Type	Description
<code>oldcallback</code>	FORTRAN: INTEGER C: int	FORTRAN: Address of the former callback function. C: Pointer to the former callback function.

Description

The callback function is called on each VML mathematical function error if VML_ERRMODE_CALLBACK error mode is set (see [Table 9-14](#)).

Use the `vm1SetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

GetErrorCallBack

Gets the additional error handler callback function.

Syntax

Fortran:

```
callback = vm1geterrorcallback( )
```

C:

```
callback = vm1GetErrorCallBack( void );
```

Output Parameters

Name

callback

Description

FORTRAN: Address of the callback function

C: Pointer to the callback function

ClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

Fortran:

```
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldcallback = vmlClearErrorCallBack( void );
```

Output Parameters

Name

Type

oldcallback **FORTRAN:** INTEGER

C: int

Description

FORTRAN: Address of the former callback function

C: Pointer to the former callback function

Statistical Functions

Statistical functions in Intel® MKL are known as Vector Statistical Library (VSL) that is designed for the purpose of

- generating vectors of pseudorandom and quasi-random numbers
- performing mathematical operations of convolution and correlation.

The corresponding functionality is described in the respective [Random Number Generators](#) and [Convolution and Correlation](#) sections.

Random Number Generators

VSL provides a set of routines implementing commonly used pseudo- or quasi-random number generators with continuous and discrete distribution. To speed up performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and the library of vector mathematical functions (VML, see [Chapter 9, “Vector Mathematical Functions”](#)).

VSL provides interfaces both for FORTRAN and C languages. For users of the C and C++ languages the `mkl_vsl.h` header file is provided. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.fi` header file is provided. Both header files are found in the following directory:

```
${MKL}/include
```

The `mkl_vsl.fi` header is intended for using via the FORTRAN `include` clause and is compatible with both standard forms of F90/F95 sources — the free and 72-columns fixed forms. If you need to use the VSL interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.fi'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the FORTRAN use clauses referencing to the VSL interface:

```
use mkl_vsl_type
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.fi` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VSL interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

NOTE. For FORTRAN interface, VSL provides both subroutine-style interface and function-style interface. Default interface in this case is a function-style interface. Subroutine-style interface is provided for backward compatibility only. To use subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.fi` by changing the line `include 'mkl_vsl.fi'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

Function-style interface, unlike subroutine-style interface, allows user to get error status of each routine.

All VSL routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are either pseudorandom number generators or quasi-random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Subroutines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Subroutines](#) section).

The last two categories are referred to as service routines.

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to 'Random Numbers' section in [VSL Notes](#) document provided with Intel® MKL.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate

transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VSL Notes](#) for the description of methods available for each generator.

The *stream descriptor* specifies which BRNG should be used in a given transformation method. See 'Random Streams and RNGs in Parallel Computation' section of [VSL Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \dots\}$.
Z	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).

$\oplus$ or **xor**

Bitwise exclusive OR.

$$C_{\alpha}^k \text{ or } \binom{\alpha}{k}$$

Binomial coefficient or combination ($\alpha \in R, \alpha \geq 0; k \in N \cup \{0\}$).

$$C_{\alpha}^k = 1$$

For $\alpha \geq k$ binomial coefficient is defined as

$$C_{\alpha}^k = \frac{\alpha(\alpha - 1) \dots (\alpha - k + 1)}{k!}$$

If $\alpha < k$, then

$$C_{\alpha}^k = 0$$

$\Phi(x)$

Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

	defined over $-\infty < x < +\infty$.
	$\Phi(-\infty) = 0, \Phi(+\infty) = 1$.
$\Gamma(\alpha)$	The complete gamma function
	$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$
	where $\alpha > 0$.
$B(p, q)$	The complete beta function
	$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$
	where $p > 0$ and $q > 0$.
$LCG(a, c, m)$	Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where a is called the <i>multiplier</i> , c is called the <i>increment</i> , and m is called the <i>modulus</i> of the generator.
$MCG(a, m)$	Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment c is taken to be 0.
$GFSR(p, q)$	Generalized Feedback Shift Register Generator
	$x_n = x_{n-p} \oplus x_{n-q}$.

Naming Conventions

The names of all VSL functions in FORTRAN are lowercase; names in C may contain both lowercase and uppercase letters.

The names of generator routines have the following structure:

`v<type of result>rng<distribution>` for FORTRAN-interface

`v<type of result>Rng<distribution>` for C-interface,

where `v` is the prefix of a VSL vector function, and the field `<type of result>` is either `s`, `d`, or `i` and specifies one of the following types:

<code>s</code>	REAL for FORTRAN-interface float for C-interface
<code>d</code>	DOUBLE PRECISION for FORTRAN-interface double for C-interface
<code>i</code>	INTEGER for FORTRAN-interface int for C-interface

Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case. The prefix `rng` indicates that the routine is a random generator, and the `<distribution>` field specifies the type of statistical distribution.

Names of service routines follow the template below:

`vsl<name>`,

where `vsl` is the prefix of a VSL service function. The field `<name>` contains a short function name. For a more detailed description of service routines refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

Prototype of each generator routine corresponding to a given probability distribution fits the following structure:

`<function name>( method, stream, n, r, [<distribution parameters >] ),`

where

- `method` is the number specifying the method of generation. A detailed description of this parameter can be found in [Distribution Generators](#) section. See the next page for `method` name structure definition.
- `stream` defines the random stream descriptor and must have a nonzero value. Random streams and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- `n` defines the number of random values to be generated. If `n` is less than or equal to zero, no values are generated. Furthermore, if `n` is negative, an error condition is set.
- `r` defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least `n` random numbers.

Additional parameters included into `<distribution parameters>` field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VSL routine. For example, to obtain a vector `r`, composed of `n` independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value `a` and standard deviation `sigma`, write the following:

for FORTRAN-interface

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

for C-interface

```
status = vsRngGaussian( method,
stream, n, r, a, sigma )
```

The name of a *method* parameter has the following structure:

```
VSL_METHOD_<precision><distribution>_<method>,
```

```
VSL_METHOD_<precision><distribution>_<method>_ACCURATE,
```

where

<code><precision></code>	<i>s</i>	for single precision continuous distribution
	<i>D</i>	for double precision continuous distribution
	<i>I</i>	for discrete distribution
<code><distribution></code>	probability distribution	
<code><method></code>	method name.	

Type of name structure for *method* parameter corresponds to fast and accurate modes of random number generation (see “Distribution Generators” section and [VSL Notes](#) for details).

Method names `VSL_METHOD_<precision><distribution>_<method>` and `VSL_METHOD_<precision><distribution>_<method>_ACCURATE` should be used with `vsl<precision>Rng<distribution>` function only, where

<code><precision></code>	<i>s</i>	for single precision continuous distribution
	<i>d</i>	for double precision continuous distribution
	<i>i</i>	for discrete distribution
<code><distribution></code>	probability distribution.	

[Table 10-1](#) provides specific predefined values of the *method* name. The third column contains names of the functions that use the given method.

Table 10-1 Values of `<method>` in *method* parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uniform (discrete), UniformBits

Method	Short Description	Functions
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian , GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian , GaussianMV , Lognormal
ICDF	Inverse cumulative distribution function method.	Exponential , Laplace , Weibull , Cauchy , Rayleigh , Gumbel , Bernoulli , Geometric , Gaussian , GaussianMV
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma

Method	Short Description	Functions
CJA	For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Jöhnk method is used, if $q + K \cdot p^2 + C \leq 0$ ($K = 0.852...$, $C = -0.956...$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Jöhnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Jöhnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $ntrial \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail	Binomial
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: – rectangular – left exponential tail – right exponential tail	Hypergeometric
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail; otherwise, table lookup method is used.	Poisson

Method	Short Description	Functions
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	<a>Poisson , <a>PoissonV
NBAR	Acceptance/rejection method for ,	<a>NegBinomial

$$\frac{(a-1) \cdot (1-p)}{p} \geq 100$$

- with decomposition into 5 regions:
- rectangular
 - 2 trapezoid
 - left exponential tail
 - right exponential tail

Basic Generators

VSL provides the following BRNGs, which differ in speed and other properties:

- the 32-bit multiplicative congruential pseudorandom number generator $MCG(1132489760, 2^{31}-1)$ [L'Ecuyer99]
- the 32-bit generalized feedback shift register pseudorandom number generator $GFSR(250,103)$ [Kirkpatrick81]
- the combined multiple recursive pseudorandom number generator $MRG-32k3a$ [L'Ecuyer99a]
- the 59-bit multiplicative congruential pseudorandom number generator $MCG(13^{13}, 2^{59})$ from NAG Numerical Libraries [NAG]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [NAG]
- Mersenne Twister pseudorandom number generator $MT19937$ [Matsumoto98] with period length $2^{19937}-1$ of the produced sequence

- Set of 1024 Mersenne Twister pseudorandom number generators *MT2203* [Matsumoto98], [Matsumoto00]. Each of them generates a sequence of period length equal to $2^{2203}-1$. Parameters of the generators provide mutual independence of the corresponding sequences.

Besides these pseudorandom number generators, VSL provides two basic quasi-random number generators:

- Sobol quasi-number generator [Sobol76], [Bratley88], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Niederreiter quasi-random number generator [Bratley92], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).

Also see some testing results for the generators in [VSL Notes](#) and comparative performance data at http://www.intel.com/software/products/mkl/data/vsl/vsl_performance_data.htm.

VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Subroutines](#) section.

For some basic generators, VSL provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 1024 generators designed to create up to 1024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Subroutines](#) section.

There is also an option to utilize externally generated random numbers in VSL distribution generator routines. For this purpose VSL provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval.

Such basic generators are called the abstract basic random number generators.
See [VSL Notes](#) for a more detailed description of the generator properties.

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Table 10-2 Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 1024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.

See [VSL Notes](#) for detailed description.

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. Users have no direct access to these sequences and operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VSL Notes](#) for details.

NOTE. Random streams associated with abstract basic random number generator are called the abstract random streams. See [VSL Notes](#) for detailed description of abstract streams and their use.

User can create unlimited number of random streams by VSL [Service Routines](#) like [NewStream](#) and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine [DeleteStream](#).

VSL provides service functions [SaveStreamF](#) and [LoadStreamF](#) to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VSL Notes](#) for detailed description.

Data Types

FORTRAN:

```
TYPE VSL_STREAM_STATE
  INTEGER*4 descriptor1
  INTEGER*4 descriptor2
ENDTYPE VSL_STREAM_STATE
```

C:

```
typedef (void*) VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

Error Reporting

VSL routines return status codes of the performed operation to report errors and warnings to the calling program. Thus, it is up to the application to perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL_ERROR_<ERROR_NAME> - indicates VSL errors

VSL_WARNING_<WARNING_NAME> - indicates VSL warnings.

VSL errors are of negative values while warnings are of positive values. The status code of zero value indicates that the operation is completed successfully: VSL_ERROR_OK (or synonymic VSL_STATUS_OK).

Table 10-3 Status Codes and Messages

Status Code	Message
VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Input argument value is not valid.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_ERROR_BAD_STREAM	The random stream is invalid.
VSL_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_ERROR_FILE_READ	Indicates an error in reading the file.
VSL_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_BAD_FILE_FORMAT	File format is unknown.

Status Code	Message
VSL_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_ERROR_BAD_STREAM_STATE_SIZE	The value in <code>StreamStateSize</code> field is bad.
VSL_ERROR_BAD_WORD_SIZE	The value in <code>WordSize</code> field is bad.
VSL_ERROR_BAD_NSEEDS	The value in <code>NSeeds</code> field is bad.
VSL_ERROR_BAD_NBITS	The value in <code>NBits</code> field is bad.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table 10-4](#) lists all available service routines

Table 10-4 Service Routines

Routine	Short Description
NewStream	Creates and initializes a random stream.
NewStreamEx	Creates and initializes a random stream for the generators with multiple initial conditions.
iNewAbstractStream	Creates and initializes an abstract random stream for integer arrays.
dNewAbstractStream	Creates and initializes an abstract random stream for double precision floating-point arrays.

Routine	Short Description
<code>sNewAbstractStream</code>	Creates and initializes an abstract random stream for single precision floating-point arrays.
<code>DeleteStream</code>	Deletes previously created stream.
<code>CopyStream</code>	Copies a stream to another stream.
<code>CopyStreamState</code>	Creates a copy of a random stream state.
<code>SaveStreamF</code>	Writes a stream to a binary file.
<code>LoadStreamF</code>	Reads a stream from a binary file.
<code>LeapfrogStream</code>	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
<code>SkipAheadStream</code>	Initializes the stream by the skip-ahead method.
<code>GetStreamStateBrng</code>	Obtains the index of the basic generator responsible for the generation of a given random stream.
<code>GetNumRegBrngs</code>	Obtains the number of currently registered basic generators.

NOTE. In the above table, the `vs1` prefix in the function names is omitted. In the function reference this prefix is always used in function prototypes and code examples.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream (`NewStream`, `NewStreamEx`, `CopyStream`, `CopyStreamState`, `LeapfrogStream`, `SkipAheadStream`).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream (`DeleteStream`).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the `DeleteStream` function to delete all the streams afterwards.

NewStream

Creates and initializes a random stream.

Syntax

Fortran:

```
status = vslnewstream( stream, brng, seed )
```

C:

```
status = vslNewStream( &stream, brng, seed );
```

Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. See [VSL Notes](#) for a more detailed description of stream initialization for different basic generators.

NOTE. This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vslldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Index of the basic generator to initialize the stream. See Table 10-2 for specific value.
<i>seed</i>	FORTRAN: INTEGER, INTENT (IN) C: unsigned int	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is

Name	Type	Description
		greater than the dimension that <code>brng</code> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Stream state descriptor

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .

NewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

Fortran:

```
status = vslnewstreamex( stream, brng, n, params )
```

C:

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Description

This function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use [NewStream](#),

which is analogous to `vslNewStreamEx` except that it takes only one 32-bit initial condition. In particular, `vslNewStreamEx` may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VSL Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VSL Notes](#) for the format for their passing and registration in VSL.

NOTE. This function is not applicable for abstract basic random number generators. Please use `vsliNewAbstractStream`, `vslsNewAbstractStream` or `vsldNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

Input Parameters

Name	Type	Description
<i>brng</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Index of the basic generator to initialize the stream. See Table 10-2 for specific value.
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: unsigned int	Number of initial conditions contained in <i>params</i>
<i>params</i>	FORTTRAN: INTEGER, INTENT (IN) C: const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Stream state descriptor

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .

iNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

Fortran:

```
status = vslinewabstractstream( stream, n, ibuf, icallback )
```

C:

```
status = vsliNewAbstractStream( &stream, n, ibuf, icallback );
```

Description

This function creates a new abstract stream and associates it with an integer array *ibuf* and user's callback function *icallback* that is intended for updating of *ibuf* content.

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN: INTEGER, INTENT (IN)	Size of the array <i>ibuf</i>

Name	Type	Description
	C: <code>int</code>	
<i>ibuf</i>	FORTRAN: <code>INTEGER, INTENT (IN)</code> C: <code>unsigned int*</code>	Array of <i>n</i> 32-bit integers
<i>icallback</i>	FORTRAN: See <i>Note</i> below C: See <i>Note</i> below	FORTRAN: Address of the callback function used for <i>ibuf</i> update C: Pointer to the callback function used for <i>ibuf</i> update

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN: <code>TYPE (VSL_STREAM_STATE), TINTENT (OUT)</code> C: <code>VSLStreamStatePtr*</code>	Descriptor of the stream state structure

NOTE. Format of the callback function in Fortran:

```

INTEGER FUNCTION IUPDATEFUNC(C) ( stream, n, ibuf, nmin, nmax, idx )
TYPE (VSL_STREAM_STATE), POINTER :: stream[reference]
INTEGER (KIND=4), INTENT (IN)      :: n[reference]
INTEGER (KIND=4), INTENT (OUT)     :: ibuf[reference] (0:n-1)
INTEGER (KIND=4), INTENT (IN)      :: nmin[reference]
INTEGER (KIND=4), INTENT (IN)      :: nmax[reference]
INTEGER (KIND=4), INTENT (IN)      :: idx[reference]

```

Format of the callback function in C:

```

int iUpdateFunc( VSLStreamStatePtrstream, int* n, unsigned int ibuf[], int* nmin,
int* nmax, int* idx );

```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-5](#) gives the description of the callback function parameters.

Table 10-5 icallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

dNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

Fortran:

```
status = vsldnewabstractstream( stream, n, dbuf, a, b, dcallback )
```

C:

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Description

This function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a double precision array *dbuf* and user's callback function *dcallback* that is intended for updating of *dbuf* content.

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Size of the array <i>dbuf</i>
<i>dbuf</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double*	Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double	Left boundary <i>a</i>
<i>b</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double	Right boundary <i>b</i>
<i>dcallback</i>	FORTTRAN: See <i>Note</i> below C: See <i>Note</i> below	FORTTRAN: Address of the callback function used for update of the array <i>dbuf</i> C: Pointer to the callback function used for update of the array <i>dbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE. Format of the callback function in Fortran:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )  
TYPE (VSL_STREAM_STATE),POINTER :: stream[reference]  
  
INTEGER (KIND=4), INTENT (IN)      :: n[reference]  
REAL (KIND=8),   INTENT (OUT)     :: dbuf[reference] (0:n-1)  
INTEGER (KIND=4), INTENT (IN)      :: nmin[reference]  
INTEGER (KIND=4), INTENT (IN)      :: nmax[reference]  
INTEGER (KIND=4), INTENT (IN)      :: idx[reference]
```

Format of the callback function in C:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int*  
nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-6](#) gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update

Parameters	Short Description
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

sNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

Fortran:

```
status = vslnsnewabstractstream( stream, n, sbuf, a, b, scallback )
```

C:

```
status = vslnsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Description

This function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b). The function associates the stream with a single precision array *sbuf* and user's callback function *scallback* that is intended for updating of *sbuf* content.

Input Parameters

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Size of the array <i>sbuf</i>
<i>sbuf</i>	FORTTRAN: REAL, INTENT (IN) C: float*	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (<i>a</i> , <i>b</i>)
<i>a</i>	FORTTRAN: REAL, INTENT (IN) C: float	Left boundary <i>a</i>
<i>b</i>	FORTTRAN: REAL, INTENT (IN) C: float	Right boundary <i>b</i>
<i>scallback</i>	FORTTRAN: See <i>Note</i> below C: See <i>Note</i> below	FORTTRAN: Address of the callback function used for update of the array <i>sbuf</i> C: Pointer to the callback function used for update of the array <i>sbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

**NOTE.** Format of the callback function in Fortran:

```

INTEGER FUNCTION SUPDATEFUNC(C)( stream, n, sbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE), POINTER :: stream[reference]
INTEGER(KIND=4), INTENT(IN)      :: n[reference]
REAL(KIND=4), INTENT(OUT)       :: sbuf[reference](0:n-1)
INTEGER(KIND=4), INTENT(IN)      :: nmin[reference]
INTEGER(KIND=4), INTENT(IN)      :: nmax[reference]
INTEGER(KIND=4), INTENT(IN)      :: idx[reference]

```

Format of the callback function in C:

```

int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int*
nmax, int* idx );

```

The callback function returns the number of elements in the array actually updated by the function. [Table 10-7](#) gives the description of the callback function parameters.

Table 10-7 scallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BAD_ARG	Parameter <i>n</i> is not positive.

VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

DeleteStream

Deletes a random stream.

Syntax

Fortran:

```
status = vsldeletestream( stream )
```

C:

```
status = vslDeleteStream( &stream );
```

Description

This function deletes the random stream created by one of the initialization functions.

Input/Output Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	FORTTRAN: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid. C: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to NULL.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

CopyStream

Creates a copy of a random stream.

Syntax

Fortran:

```
status = vslcopystream( newstream, srcstream )
```

C:

```
status = vslCopyStream( &newstream, srcstream );
```

Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream to be copied C: Pointer to the stream state structure to be copied

Output Parameters

Name	Type	Description
<i>newstream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr*	Copied stream descriptor

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.

VSL_ERROR_MEM_FAILURE

System cannot allocate memory for *newstream*.

CopyStreamState

Creates a copy of a random stream state.

Syntax

Fortran:

```
status = vslcopystreamstate( deststream, srcstream )
```

C:

```
status = vslCopyStreamState( deststream, srcstream );
```

Description

The function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. En error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike [CopyStream](#) function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `CopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTTRAN:	FORTTRAN: Descriptor of the destination stream where the state of <i>srcstream</i> stream is copied
	TYPE (VSL_STREAM_STATE),	
	INTENT (IN)	C: Pointer to the stream state structure, from which the state structure is copied
	C: VSLStreamStatePtr	

Output Parameters

Name	Type	Description
<i>deststream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream with the state to be copied C: Pointer to the stream state structure where the stream state is copied

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.
VSL_ERROR_BRNGS_INCOMPATIBLE	BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> .

SaveStreamF

Writes random stream descriptive data to binary file.

Syntax

Fortran:

```
errstatus = vslsavestreamf( stream, fname )
```

C:

```
errstatus = vslSaveStreamF( stream, fname );
```

Description

This function writes the random stream descriptive data to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. Random stream *stream* must be a valid stream created by [NewStream](#)-like or [CopyStream](#)-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. Random stream can be read from the binary file using [LoadStreamF](#) function.

Input Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Random stream to be written to the file
<i>fname</i>	FORTTRAN: CHARACTER (*), INTENT (IN) C: char*	FORTTRAN: File name specified as a C-style null-terminated string C: File name specified as a Fortran-style character string

Output Parameters

Name	Type	Description
<i>errstatus</i>	FORTTRAN: INTEGER C: int	Error status of the operation

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>fname</i> or <i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.

LoadStreamF

Creates new stream and reads stream descriptive data from binary file.

Syntax

Fortran:

```
errstatus = vslloadstreamf( stream, fname )
```

C:

```
errstatus = vslLoadStreamF( &stream, fname );
```

Description

This function creates a new stream and reads stream descriptive data from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use [SaveStreamF](#) function.

Input Parameters

Name	Type	Description
<i>fname</i>	FORTTRAN: CHARACTER (*), INTENT (IN)	FORTTRAN: File name specified as a C-style null-terminated string
	C: char*	C: File name specified as a Fortran-style character string

Output Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (OUT)	FORTTRAN: Descriptor of a new random stream
	C: VSLStreamStatePtr*	C: Pointer to a new random stream

Name	Type	Description
<i>errstatus</i>	FORTRAN: INTEGER C: int	Error status of the operation
Return Values		
VSL_ERROR_OK, VSL_STATUS_OK		Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR		<i>fname</i> is a NULL pointer.
VSL_ERROR_FILE_OPEN		Indicates an error in opening the file.
VSL_ERROR_FILE_WRITE		Indicates an error in writing the file.
VSL_ERROR_FILE_CLOSE		Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE		System cannot allocate memory for internal needs.
VSL_ERROR_BAD_FILE_FORMAT		Unknown file format.
VSL_ERROR_UNSUPPORTED_FILE_VER		File format version is unsupported.

LeapfrogStream

Initializes a stream using the leapfrog method.

Syntax

Fortran:

```
status = vslleapfrogstream( stream, k, nstreams )
```

C:

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Description

The function allows generating random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from original stream across *nstreams* buffers without generating the original random sequence with subsequent manual distribution. One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes. The

function initializes the original random stream (see [Figure 10-1](#)) to generate random numbers for the computational node k , $0 \leq k < nstreams$, where $nstreams$ is the largest number of computational nodes used.

Figure 10-1 Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VSL Notes](#) for details.

For quasi-random basic generators the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case $nstreams$ parameter should be equal to the dimension of the quasi-random vector while k parameter should be the index of a component to be generated ($0 \leq k < nstreams$). Other parameters values are not allowed.

The following code examples illustrate the initialization of three independent streams using the leapfrog method:

Example 10-1 FORTRAN Code for Leapfrog Method

```
...
TYPE(VSL_STREAM_STATE)  ::stream1
TYPE(VSL_STREAM_STATE)  ::stream2
TYPE(VSL_STREAM_STATE)  ::stream3
! Creating 3 identical streams
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
status = vslcopystream(stream2, stream1)
status = vslcopystream(stream3, stream1)
! Leapfrogging the streams

status = vslleapfrogstream(stream1, 0, 3)
status = vslleapfrogstream(stream2, 1, 3)
status = vslleapfrogstream(stream3, 2, 3)
! Generating random numbers

...
! Deleting the streams

status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Example 10-2 C Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);
/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);
/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status =
vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream to which leapfrog method is applied C: Pointer to the stream state structure to which leapfrog method is applied
<i>k</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Index of the computational node, or stream number
<i>nstreams</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Largest number of computational nodes, or stride

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

SkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

Fortran:

```
status = vslskipaheadstream( stream, nskip )
```

C:

```
status = vslSkipAheadStream( stream, nskip);
```

Description

This function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `SkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see [Figure 10-2](#)).

Figure 10-2 Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VSL Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Thus to skip *NS* quasi-random vectors, set *nskip* parameter equal to the *NS*DIMEN*, where *DIMEN* is the dimension of quasi-random vector.

The following code examples illustrate how to initialize three independent streams using `SkipAheadStream` function:

Example 10-3 FORTRAN Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE)  ::stream1
type(VSL_STREAM_STATE)  ::stream2
type(VSL_STREAM_STATE)  ::stream3
! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
! Skipping ahead by 7 elements the 2nd stream

status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);
! Skipping ahead by 7 elements the 3rd stream

status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);
! Generating random numbers

...
! Deleting the streams

status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

Example 10-4 C Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);
/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);
/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Input Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream to which block-splitting method is applied C: Pointer to the stream state structure to which block-splitting method is applied

Name	Type	Description
<i>nskip</i>	FORTTRAN: INTEGER(KIND=8), INTENT(IN) C: long long	Number of skipped elements

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.

GetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

Fortran:

```
brng = vslgetstreamstatebrng( stream )
```

C:

```
brng = vslGetStreamStateBrng( stream );
```

Description

This function retrieves the index of a basic generator used for generation of a given random stream.

Input Parameters

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE(VSL_STREAM_STATE), TINTENT(IN) C: long long	FORTTRAN: Descriptor of the stream state C: Pointer to the stream state structure

Name	Type	Description
	C: <code>VSLStreamStatePtr</code>	

Output Parameters

Name	Type	Description
<i>brng</i>	FORTTRAN: <code>INTEGER</code> C: <code>int</code>	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

Return Values

<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a <code>NULL</code> pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.

GetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

Fortran:

```
nregbrngs = vslgetnumregbrngs( )
```

C:

```
nregbrngs = vslGetNumRegBrngs( void );
```

Description

This function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by `VSL_MAX_REG_BRNGS` parameter.

Output Parameters

Name	Type	Description
<i>nregbrngs</i>	FORTRAN: INTEGER C: int	Number of basic generators registered at the moment of the function call

Distribution Generators

VSL routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence for both FORTRAN and C-interface and the explanation of input and output parameters. [Table 10-8](#) and [Table 10-9](#) list the random number generator routines, together with used data types, output distributions, and sets correspondence between data types of the generator routines and called basic random number generators.

Table 10-8 Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Type	Data Description
Uniform	s, d	s, d	Uniform continuous distribution on the interval $[a, b]$.
Gaussian	s, d	s, d	Normal (Gaussian) distribution.
GaussianMV	s, d	s, d	Multivariate normal (Gaussian) distribution.
Exponential	s, d	s, d	Exponential distribution.
Laplace	s, d	s, d	Laplace distribution (double exponential distribution).
Weibull	s, d	s, d	Weibull distribution.
Cauchy	s, d	s, d	Cauchy distribution.
Rayleigh	s, d	s, d	Rayleigh distribution.
Lognormal	s, d	s, d	Lognormal distribution.
Gumbel	s, d	s, d	Gumbel (extreme value) distribution.

Type of Distribution	Data Types	BRNG Data Type	Data Description
Gamma	s, d	s, d	Gamma distribution.
Beta	s, d	s, d	Beta distribution.

Table 10-9 Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
Uniform	i	d	Uniform discrete distribution on the interval $[a, b]$.
UniformBits	i	i	Generator of integer random values with uniform bit distribution.
Bernoulli	i	s	Bernoulli distribution.
Geometric	i	s	Geometric distribution.
Binomial	i	d	Binomial distribution.
Hypergeometric	i	d	Hypergeometric distribution.
Poisson	i	s (for VSL_METHOD_IPOISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_METHOD_IPOISSON_PTPE)	Poisson distribution.
PoissonV	i	s	Poisson distribution with varying mean.
NegBinomial	i	d	Negative binomial distribution, or Pascal distribution.

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval $[a,b]$ belong to this interval irrespective of what a and b values may be. Fast mode provides high performance of generation and also guaranties that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Table 10-10 Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
Uniform	s, d
Exponential	s, d
Weibull	s, d
Rayleigh	s, d
Lognormal	s, d
Gamma	s, d
Beta	s, d

See additional details about accurate and fast mode of random number generation in [VSL Notes](#).

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

Uniform

Generates random numbers with uniform distribution.

Syntax

Fortran:

```
status = vsrnguniform( method, stream, n, r, a, b )
```

```
status = vdrnguniform( method, stream, n, r, a, b )
```

C:

```
status = vsRngUniform( method, stream, n, r, a, b );
```

```
status = vdRngUniform( method, stream, n, r, a, b );
```

Description

This function generates random numbers uniformly distributed over the interval $[a, b]$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in \mathbb{R}$; $a > b$.

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b] \\ 0, & x \notin [a, b] \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x \leq b \\ 1, & x \geq b \end{cases}, \quad -\infty < x < +\infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method; the specific values are as follows: VSL_METHOD_SUNIFORM_STD VSL_METHOD_DUNIFORM_STD VSL_METHOD_SUNIFORM_STD_ACCURATE VSL_METHOD_DUNIFORM_STD_ACCURATE Standard method.
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnguniform DOUBLE PRECISION, INTENT (IN) for vdrnguniform C: float for vsRngUniform double for vdRngUniform	Left bound a
<i>b</i>	FORTTRAN: REAL, INTENT (IN) for vsrnguniform	Right bound b

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdrnguniform	
	C: float for vsRngUniform double for vdRngUniform	

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT(OUT) for vsrnguniform DOUBLE PRECISION, INTENT(OUT) for vdrnguniform C: float* for vsRngUniform double* for vdRngUniform	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b]$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Gaussian

Generates normally distributed random numbers.

Syntax

Fortran:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

```
status = vdrnggaussian( method, stream, n, r, a, sigma )
```

C:

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
```

```
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

Description

This function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ , where

$a, \sigma \in \mathbb{R}$; $\sigma > 0$.

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a,\sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$$F_{a,\sigma}(x) = \Phi((x - a)/\sigma)$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SGAUSSIAN_BOXMULLER VSL_METHOD_SGAUSSIAN_BOXMULLER2 VSL_METHOD_SGAUSSIAN_ICDF VSL_METHOD_DGAUSSIAN_BOXMULLER VSL_METHOD_DGAUSSIAN_BOXMULLER2 VSL_METHOD_DGAUSSIAN_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table 10-1
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggaussian DOUBLE PRECISION, INTENT (IN) for vdrnggaussian	Mean value <i>a</i> .

Name	Type	Description
	C: float for vsRngGaussian double for vdRngGaussian	
<i>sigma</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggaussian DOUBLE PRECISION, INTENT (IN) for vdrnggaussian C: float for vsRngGaussian double for vdRngGaussian	Standard deviation σ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT (OUT) for vsrnggaussian DOUBLE PRECISION, INTENT (OUT) for vdrnggaussian C: float* for vsRngGaussian double* for vdRngGaussian	Vector of n normally distributed random numbers

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

GaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

Fortran:

```
status = vsrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
status = vdrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

C:

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Description

This function generates random numbers with d -variate normal (Gaussian) distribution with mean value a and variance-covariance matrix C , where $a \in R^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x - a)^T C^{-1}(x - a)),$$

where $x \in R^d$.

Matrix C can be represented as $C = TT^T$, where T is a lower triangular matrix - Cholesky factor of C .

Instead of variance-covariance matrix c the generation routines require Cholesky factor of c in input. To compute Cholesky factor of matrix c , the user may call MKL LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV/v?rnggaussianmv` routines (`?` means either `s` or `d` for single and double precision respectively). See [Application Notes](#) for more details.

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SGAUSSIANMV_BOXMULLER VSL_METHOD_SGAUSSIANMV_BOXMULLER2 VSL_METHOD_SGAUSSIANMV_ICDF VSL_METHOD_DGAUSSIANMV_BOXMULLER VSL_METHOD_DGAUSSIANMV_BOXMULLER2 VSL_METHOD_DGAUSSIANMV_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table 10-1
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>dimen</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Dimension d ($d \geq 1$) of output random vectors

Name	Type	Description
<i>mstorage</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	FORTTRAN: Matrix storage scheme for upper triangular matrix T^T . The routine supports three matrix storage schemes: • VSL_MATRIX_STORAGE_FULL— all $d \times d$ elements of the matrix T^T are passed, however, only the upper triangle part is actually used in the routine. • VSL_MATRIX_STORAGE_PACKED— upper triangle elements of T^T are packed by rows into a one-dimensional array. • VSL_MATRIX_STORAGE_DIAGONAL— only diagonal elements of T^T are passed. C: Matrix storage scheme for lower triangular matrix T . The routine supports three matrix storage schemes: • VSL_MATRIX_STORAGE_FULL— all $d \times d$ elements of the matrix T are passed, however, only the lower triangle part is actually used in the routine. • VSL_MATRIX_STORAGE_PACKED— lower triangle elements of T are packed by rows into a one-dimensional array. • VSL_MATRIX_STORAGE_DIAGONAL— only diagonal elements of T are passed.
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggaussianmv DOUBLE PRECISION, INTENT (IN) for vdrnggaussianmv	Mean vector a of dimension d

Name	Type	Description
	C: float* for vsRngGaussianMV double* for vdRngGaussianMV	
t	FORTTRAN: REAL, INTENT (IN) for vsrnggaussianmv DOUBLE PRECISION, INTENT (IN) for vdrnggaussianmv C: float* for vsRngGaussianMV double* for vdRngGaussianMV	FORTTRAN: Elements of the upper triangular matrix passed according to the matrix T^T storage scheme $mstorage$. C: Elements of the lower triangular matrix passed according to the matrix T storage scheme $mstorage$.

Output Parameters

Name	Type	Description
r	FORTTRAN: REAL, INTENT (OUT) for vsrnggaussianmv DOUBLE PRECISION, INTENT (OUT) for vdrnggaussianmv C: float* for vsRngGaussianMV double* for vdRngGaussianMV	Array of n random vectors of dimension $dimen$

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VSL example file.

Table 10-11 Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in Fortran two-dimensional array	spotrf for vsrnggaussianmv dpotrf for vdrnggaussianmv	'U'	Upper triangle of T^T . Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsrnggaussianmv dpptrf for vdrnggaussianmv	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Table 10-12 Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV dpotrf for vdRngGaussianMV	'U'	Upper triangle of T^T . Lower triangle is not used.

Matrix Storage Scheme	Variance-CovarianceFactorization Matrix Argument Routine	UPLO Parameter in FactorizationArgument Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV dpptrf for vdRngGaussianMV	'L' Upper triangle of T^T packed by rows into one-dimensional array.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Exponential

Generates exponentially distributed random numbers.

Syntax

Fortran:

```
status = vsrngexponential( method, stream, n, r, a, beta )  
status = vdrngexponential( method, stream, n, r, a, beta )
```

C:

```
status = vsRngExponential( method, stream, n, r, a, beta );
status = vdRngExponential( method, stream, n, r, a, beta );
```

Description

This function generates random numbers with exponential distribution that has displacement a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp (-(x - a)) / \beta , & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp (-(x - a)) / \beta , & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SEXPONENTIAL_ICDF VSL_METHOD_DEXPONENTIAL_ICDF VSL_METHOD_SEXPONENTIAL_ICDF_ACCURATE VSL_METHOD_DEXPONENTIAL_ICDF_ACCURATE Inverse cumulative distribution function method

Name	Type	Description
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrngexponential DOUBLE PRECISION, INTENT (IN) for vdrngexponential C: float for vsRngExponential C: double for vdRngExponential	Displacement <i>a</i>
<i>beta</i>	FORTTRAN: REAL, INTENT (IN) for vsrngexponential DOUBLE PRECISION, INTENT (IN) for vdrngexponential C: float for vsRngExponential double for vdRngExponential	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT (OUT) for vsrngexponential DOUBLE PRECISION, INTENT (OUT) for vdrngexponential C: float* for vsRngExponential double* for vdRngExponential	Vector of <i>n</i> exponentially distributed random numbers

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Laplace

Generates random numbers with Laplace distribution.

Syntax

Fortran:

```
status = vsrnglaplace( method, stream, n, r, a, beta )
status = vdrnglaplace( method, stream, n, r, a, beta )
```

C:

```
status = vsRngLaplace( method, stream, n, r, a, beta );
```

```
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Description

This function generates random numbers with Laplace distribution with mean value (or average) a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$. The scalefactor value determines the standard deviation as

$$\sigma = \beta\sqrt{2}$$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x-a|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, -\infty < x < +\infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SLAPLACE_ICDF VSL_METHOD_DLAPLACE_ICDF Inverse cumulative distribution function method
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnglaplace DOUBLE PRECISION, INTENT (IN) for vdrnglaplace C: float for vsRngLaplace double for vdRngLaplace	Mean value <i>a</i>
<i>beta</i>	FORTTRAN: REAL, INTENT (IN) for vsrnglaplace DOUBLE PRECISION, INTENT (IN) for vdrnglaplace C: float for vsRngLaplace	Scalefactor β .

Name	Type	Description
	double	for vdRngLaplace

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT(OUT) for vsrnglaplace DOUBLE PRECISION, INTENT(OUT) for vdrnglaplace C: float* for vsRngLaplace double* for vdRngLaplace	Vector of <i>n</i> Laplace distributed random numbers

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, <i>< 0 or > nmax</i> .
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Weibull

Generates Weibull distributed random numbers.

Syntax

Fortran:

```
status = vsrngweibull( method, stream, n, r, alpha, a, beta )
status = vdrngweibull( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

Description

This function generates Weibull distributed random numbers with displacement a , scalefactor β , and shape α , where $\alpha, \beta, a \in \mathbb{R}$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SWEIBULL_ICDF VSL_METHOD_DWEIBULL_ICDF VSL_METHOD_SWEIBULL_ICDF_ACCURATE VSL_METHOD_DWEIBULL_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated

<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrngweibull	Displacement a

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdrngweibull C: float for vsRngWeibull double for vdRngWeibull	
<i>beta</i>	FORTTRAN: REAL, INTENT(IN) for vsrngweibull DOUBLE PRECISION, INTENT(IN) for vdrngweibull C: float for vsRngWeibull double for vdRngWeibull	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT(OUT) for vsrngweibull DOUBLE PRECISION, INTENT(OUT) for vdrngweibull C: float* for vsRngWeibull double* for vdRngWeibull	Vector of n Weibull distributed random numbers

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Cauchy

Generates Cauchy distributed random values.

Syntax

Fortran:

```
status = vsrngcauchy( method, stream, n, r, a, beta )
```

```
status = vdrngcauchy( method, stream, n, r, a, beta )
```

C:

```
status = vsRngCauchy( method, stream, n, r, a, beta );
```

```
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Description

This function generates Cauchy distributed random numbers with displacement a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left(1 + \left(\frac{x-a}{\beta} \right)^2 \right)}, \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan\left(\frac{x-a}{\beta}\right), -\infty < x < +\infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SCAUCHY_ICDF VSL_METHOD_DCAUCHY_ICDF Inverse cumulative distribution function method
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsrngcauchy DOUBLE PRECISION, INTENT (IN) for vdrngcauchy C: float for vsRngCauchy double for vdRngCauchy	Displacement <i>a</i> .
<i>beta</i>	FORTRAN: REAL, INTENT (IN) for vsrngcauchy	Scalefactor β .

Name	Type	Description
	DOUBLE PRECISION, INTENT (IN) for vdrngcauchy	
	C: float for vsRngCauchy double for vdRngCauchy	

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN: REAL, INTENT (OUT) for vsrngcauchy	Vector of <i>n</i> Cauchy distributed random numbers
	DOUBLE PRECISION, INTENT (OUT) for vdrngcauchy	
	C: float* for vsRngCauchy double* for vdRngCauchy	

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Rayleigh

Generates Rayleigh distributed random values.

Syntax

Fortran:

```
status = vsrngrayleigh( method, stream, n, r, a, beta )
```

```
status = vdrnggrayleigh( method, stream, n, r, a, beta )
```

C:

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
```

```
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

Description

This function generates Rayleigh distributed random numbers with displacement a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

Rayleigh distribution is a special case of [Weibull](#) distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SRAYLEIGH_ICDF VSL_METHOD_DRAYLEIGH_ICDF VSL_METHOD_SRAYLEIGH_ICDF_ACCURATE VSL_METHOD_DRAYLEIGH_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTRAN: REAL, INTENT (IN) for vsrnggrayleigh DOUBLE PRECISION, INTENT (IN) for vdrnggrayleigh	Displacement <i>a</i>

Name	Type	Description
	C: float for vsRngRayleigh double for vdRngRayleigh	
<i>beta</i>	FORTTRAN: REAL, INTENT(IN) for vsrnggrayleigh DOUBLE PRECISION, INTENT(IN) for vdrnggrayleigh C: float for vsRngRayleigh double for vdRngRayleigh	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT(OUT) for vsrnggrayleigh DOUBLE PRECISION, INTENT(OUT) for vdrnggrayleigh C: float* for vsRngRayleigh double* for vdRngRayleigh	Vector of n Rayleigh distributed random numbers

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Lognormal

Generates lognormally distributed random numbers.

Syntax

Fortran:

```
status = vsrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

```
status = vdrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

C:

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

```
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

Description

This function generates lognormally distributed random numbers with average of distribution a and standard deviation σ of subject normal distribution, displacement b , and scalefactor β , where $a, \sigma, b, \beta \in \mathbb{R}$; $\sigma > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi((\ln((x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SLOGNORMAL_BOXMULLER2 VSL_METHOD_DLOGNORMAL_BOXMULLER2 VSL_METHOD_SLOGNORMAL_BOXMULLER2_ACCURATE VSL_METHOD_DLOGNORMAL_BOXMULLER2_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnglognormal DOUBLE PRECISION, INTENT (IN) for vdrnglognormal C: float for vsRngLognormal	Average <i>a</i> of the subject normal distribution

Name	Type	Description
	double for vdRngLognormal	
<i>sigma</i>	FORTTRAN: REAL, INTENT (IN) for vsrnglognormal DOUBLE PRECISION, INTENT (IN) for vdrnglognormal C: float for vsRngLognormal double for vdRngLognormal	Standard deviation σ of the subject normal distribution
<i>b</i>	FORTTRAN: REAL, INTENT (IN) for vsrnglognormal DOUBLE PRECISION, INTENT (IN) for vdrnglognormal C: float for vsRngLognormal double for vdRngLognormal	Displacement b
<i>beta</i>	FORTTRAN: REAL, INTENT (IN) for vsrnglognormal DOUBLE PRECISION, INTENT (IN) for vdrnglognormal C: float for vsRngLognormal double for vdRngLognormal	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT (OUT) for vsrnglognormal DOUBLE PRECISION, INTENT (OUT) for vdrnglognormal C: float* for vsRngLognormal double* for vdRngLognormal	Vector of <i>n</i> lognormally distributed random numbers

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Gumbel

Generates Gumbel distributed random values.

Syntax

Fortran:

```
status = vsrnggumbel( method, stream, n, r, a, beta )
status = vdrnggumbel( method, stream, n, r, a, beta )
```

C:

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

Description

This function generates Gumbel distributed random numbers with displacement a and scalefactor β , where $a, \beta \in R ; \beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{ \frac{1}{\beta} \exp \left(\frac{x - a}{\beta} \right) \exp \left(- \exp \left((x - a) / \beta \right) \right), -\infty < x < +\infty . \right.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp \left(- \exp \left((x - a) / \beta \right) \right), -\infty < x < +\infty$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SGUMBEL_ICDF VSL_METHOD_DGUMBEL_ICDF Inverse cumulative distribution function method
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggumbel DOUBLE PRECISION, INTENT (IN) for vdrnggumbel C: float for vsRngGumbel double for vdRngGumbel	Displacement <i>a</i> .
<i>beta</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggumbel DOUBLE PRECISION, INTENT (IN) for vdrnggumbel C: float for vsRngGumbel double for vdRngGumbel	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT (OUT) for vsrnggumbel DOUBLE PRECISION, INTENT (OUT) for vdrnggumbel C: float* for vsRngGumbel	Vector of <i>n</i> random numbers with Gumbel distribution

Name	Type	Description
	double* for vdRngGumbel	
Return Values		
VSL_ERROR_OK, VSL_STATUS_OK		Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR		<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM		<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE		Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS		Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Gamma

Generates gamma distributed random values.

Syntax

Fortran:

```
status = vsrnggamma( method, stream, n, r, alpha, a, beta )
status = vdrnggamma( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

Description

This function generates random numbers with gamma distribution that has shape parameter α , displacement a , and scale parameter β , where α, β , and $a \in \mathbb{R}$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha, a, \beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where $\Gamma(\alpha)$ is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha, a, \beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SGAMMA_GNORM VSL_METHOD_DGAMMA_GNORM VSL_METHOD_SGAMMA_GNORM_ACCURATE VSL_METHOD_DGAMMA_GNORM_ACCURATE Acceptance/rejection method using random numbers with Gaussian distribution. See brief description of the method GNORM in Table 10-1
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN)	Number of random values to be generated

Name	Type	Description
	C: int	
<i>alpha</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggamma DOUBLE PRECISION, INTENT (IN) for vdrnggamma C: float for vsRngGamma double for vdRngGamma	Shape α .
<i>a</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggamma DOUBLE PRECISION, INTENT (IN) for vdrnggamma C: float for vsRngGamma double for vdRngGamma	Displacement a .
<i>beta</i>	FORTTRAN: REAL, INTENT (IN) for vsrnggamma DOUBLE PRECISION, INTENT (IN) for vdrnggamma C: float for vsRngGamma double for vdRngGamma	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: REAL, INTENT (OUT) for vsrnggamma DOUBLE PRECISION, INTENT (OUT) for vdrnggamma	Vector of n random numbers with gamma distribution

Name	Type	Description

	C: float* for vsRngGamma	

	double* for vdRngGamma	

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM	

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE	

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS	

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Beta

Generates beta distributed random values.

Syntax

Fortran:

```
status = vsrngbeta( method, stream, n, r, p, q, a, beta )
```

```
status = vdrngbeta( method, stream, n, r, p, q, a, beta )
```

C:

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
```

```
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

Description

This function generates random numbers with beta distribution that has shape parameters p and q , displacement a , and scale parameter β , where p, q, a , and $\beta \in \mathbb{R}$; $p > 0$, $q > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p,q)\beta^{p+q-1}} (x-a)^{p-1} (\beta+a-x)^{q-1}, & a \leq x < a+\beta \\ 0, & x < a, x \geq a+\beta \end{cases}, -\infty < x < \infty,$$

where $B(p, q)$ is the complete beta function.
The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p,q)\beta^{p+q-1}} (y-a)^{p-1} (\beta+a-y)^{q-1} dy, & a \leq x < a+\beta \\ 1, & x \geq a+\beta \end{cases}, -\infty < x < \infty.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_SBETA_CJA VSL_METHOD_DBETA_CJA VSL_METHOD_SBETA_CJA_ACCURATE VSL_METHOD_DBETA_CJA_ACCURATE See brief description of the method CJA in Table 10-1
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN)	Number of random values to be generated

Name	Type	Description
	C: int	
p	FORTTRAN: REAL, INTENT (IN) for vsrngbeta DOUBLE PRECISION, INTENT (IN) for vdrngbeta C: float for vsRngBeta double for vdRngBeta	Shape p
q	FORTTRAN: REAL, INTENT (IN) for vsrngbeta DOUBLE PRECISION, INTENT (IN) for vdrngbeta C: float for vsRngBeta double for vdRngBeta	Shape q
a	FORTTRAN: REAL, INTENT (IN) for vsrngbeta DOUBLE PRECISION, INTENT (IN) for vdrngbeta C: float for vsRngBeta double for vdRngBeta	Displacement a .
β	FORTTRAN: REAL, INTENT (IN) for vsrngbeta DOUBLE PRECISION, INTENT (IN) for vdrngbeta C: float for vsRngBeta double for vdRngBeta	Scalefactor β .

Output Parameters

Name	Type	Description
r	FORTTRAN: REAL, INTENT (OUT) for vsrngbeta DOUBLE PRECISION, INTENT (OUT) for vdrngbeta C: float* for vsRngBeta double* for vdRngBeta	Vector of n random numbers with beta distribution

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	$stream$ is a NULL pointer.
VSL_ERROR_BAD_STREAM	$stream$ is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

Uniform

Generates random numbers uniformly distributed over the interval $[a, b)$.

Syntax

Fortran:

`status = virnguniform( method, stream, n, r, a, b )`

C:

```
status = viRngUniform( method, stream, n, r, a, b );
```

Description

This function generates random numbers uniformly distributed over the interval $[a, b)$, where a, b are the left and right bounds of the interval respectively, and $a, b \in \mathbb{Z}; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in \mathbb{R}. \\ 1, & x \geq b \end{cases}$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method; dummy and set to 0 in case of uniform distribution. The specific value is as follows: VSL_METHOD_IUNIFORM_STD Standard method. Currently there is only one method for this distribution generator.

Name	Type	Description
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Left interval bound <i>a</i>
<i>b</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Right interval bound <i>b</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b)$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

UniformBits

Generates integer random values with uniform bit distribution.

Syntax

Fortran:

```
status = virnguniformbits( method, stream, n, r )
```

C:

```
status = viRngUniformBits( method, stream, n, r );
```

Description

This function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit *LCG* only 24 higher bits of an integer value can be considered random. See [VSL Notes](#) for details.

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method; dummy and set to 0. The specific value is as follows: VSL_METHOD_IUNIFORMBITS_STD Standard method. Currently there is only one method for this distribution generator.
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN)	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Name	Type	Description
	C: VSLStreamStatePtr	
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN: INTEGER, INTENT (OUT) C: unsigned int*	FORTRAN: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>wordsize</i> of the structure VSL_BRNG_PROPERTIES. The total number of bits that are actually used to store the value are contained in the field <i>nbits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties. C: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure VSLBRngProperties. The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR
VSL_ERROR_BAD_STREAM
VSL_ERROR_BAD_UPDATE

VSL_ERROR_NO_NUMBERS

stream is a NULL pointer.

stream is not a valid random stream.

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Bernoulli

Generates Bernoulli distributed random values.

Syntax

Fortran:

```
status = virngbernoulli( method, stream, n, r, p )
```

C:

```
status = viRngBernoulli( method, stream, n, r, p );
```

Description

This function generates Bernoulli distributed random numbers with probability p of a single trial success, where

$p \in \mathbb{R}; 0 \leq p \leq 1$.

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success p , and to 0 with probability $1 - p$.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in R. \\ 1, & x \geq 1 \end{cases}$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific value is as follows: VSL_METHOD_IBERNOULLI_ICDF Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>p</i>	FORTRAN: DOUBLE PRECISION, INTENT (IN) C: double	Success probability <i>p</i> of a trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> Bernoulli distributed random values

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Geometric

Generates geometrically distributed random values.

Syntax

Fortran:

```
status = virnggeometric( method, stream, n, r, p )
```

C:

```
status = viRngGeometric( method, stream, n, r, p );
```

Description

This function generates geometrically distributed random numbers with probability p of a single trial success, where $p \in \mathbb{R}$; $0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, \quad k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \leq x \end{cases} \quad x \in \mathbb{R}.$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific value is as follows: VSL_METHOD_IGEOMETRIC_ICDF Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>p</i>	FORTRAN: DOUBLE PRECISION, INTENT (IN) C: double	Success probability <i>p</i> of a trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> geometrically distributed random values

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Binomial

Generates binomially distributed random numbers.

Syntax

Fortran:

```
status = virngbinomial( method, stream, n, r, ntrial, p )
```

C:

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Description

This function generates binomially distributed random numbers with number of independent Bernoulli trials m , and with probability p of a single trial success, where $p \in R$; $0 \leq p \leq 1$, $m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1-p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific value is as follows: VSL_METHOD_IBINOMIAL_BTPE See brief description of the BTPE method in Table 10-1 .
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>ntrials</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number of independent trials m
<i>p</i>	FORTRAN: DOUBLE PRECISION, INTENT (IN) C: double	Success probability p of a single trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> binomially distributed random values

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Hypergeometric

Generates hypergeometrically distributed random values.

Syntax

Fortran:

```
status = virnghypergeometric( method, stream, n, r, l, s, m )
```

C:

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Description

This function generates hypergeometrically distributed random values with lot size *l*, size of sampling *s*, and number of marked elements in the lot *m*, where $l, m, s \in \mathbb{N} \setminus \{0\}$; $l \geq \max(s, m)$.

Consider a lot of 1 elements comprising m “marked” and $1-m$ “unmarked” elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{1-m}^{s-k}}{C_1^s}$$

, $k \in \{\max(0, s + m - 1), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{1,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - 1) \\ \sum_{k=\max(0,s+m-1)}^{\lfloor x \rfloor} \frac{C_m^k C_{1-m}^{s-k}}{C_1^s}, & \max(0, s + m - 1) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific value is as follows: VSL_METHOD_IHYPERGEOMETRIC_H2PE See brief description of the H2PE method in Table 10-1
<i>stream</i>	FORTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure

Name	Type	Description
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>l</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Lot size <i>l</i>
<i>s</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Size of sampling without replacement <i>s</i>
<i>m</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of marked elements <i>m</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> hypergeometrically distributed random values

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, <i>< 0</i> or <i>> nmax</i> .
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Poisson

Generates Poisson distributed random values.

Syntax

Fortran:

```
status = virngpoisson( method, stream, n, r, lambda )
```

C:

```
status = viRngPoisson( method, stream, n, r, lambda );
```

Description

This function generates Poisson distributed random numbers with distribution parameter λ , where $\lambda \in R$; $\lambda > 0$.

The probability distribution is given by:

$$P(X = k) = \frac{\lambda^k e^{-\lambda}}{k!},$$

$k \in \{0, 1, 2, \dots\}$.

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific values are as follows: VSL_METHOD_IPOISSON_PTPE VSL_METHOD_IPOISSON_POISNORM See brief description of the PTPE and POISNORM methods in Table 10-1 .
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>lambda</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double	Distribution parameter λ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> Poisson distributed random values

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

PoissonV

Generates Poisson distributed random values with varying mean.

Syntax

Fortran:

```
status = virngpoissonv( method, stream, n, r, lambda )
```

C:

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Description

This function generates n Poisson distributed random numbers $x_i (i = 1, \dots, n)$ with distribution parameter λ_i , where $\lambda_i \in \mathbb{R}; \lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific value is as follows: VSL_METHOD_IPOISSONV_POISNORM See brief description of the POISNORM method in Table 10-1
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>lambda</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double*	Array of <i>n</i> distribution parameters λ_i .

Output Parameters

Name	Type	Description
<i>r</i>	FORTTRAN: INTEGER, INTENT (OUT) C: int*	Vector of <i>n</i> Poisson distributed random values

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR

stream is a NULL pointer.

VSL_ERROR_BAD_STREAM

stream is not a valid random stream.

VSL_ERROR_BAD_UPDATE

Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.

VSL_ERROR_NO_NUMBERS

Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

NegBinomial

Generates random numbers with negative binomial distribution.

Syntax

Fortran:

```
status = virngnegbinomial( method, stream, n, r, a, p )
```

C:

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Description

This function generates random numbers with negative binomial distribution and distribution parameters a and p , where $p, a \in \mathbb{R}$; $0 < p < 1$; $a > 0$.

If the first distribution parameter $a \in \mathbb{N}$, this distribution is the same as Pascal distribution. If $a \in \mathbb{N}$, the distribution can be interpreted as the expected time of a -th success in a sequence of Bernoulli trials, when the probability of success is p .

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1-p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1-p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Input Parameters

Name	Type	Description
<i>method</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Generation method. The specific value is: VSL_METHOD_INEGBINOMIAL_NBAR See brief description of the NBAR method in Table 10-1
<i>stream</i>	FORTTRAN: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	FORTTRAN: descriptor of the stream state structure. C: pointer to the stream state structure
<i>n</i>	FORTTRAN: INTEGER, INTENT (IN) C: int	Number of random values to be generated
<i>a</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double	The first distribution parameter <i>a</i>
<i>p</i>	FORTTRAN: DOUBLE PRECISION, INTENT (IN) C: double	The second distribution parameter <i>p</i>

Output Parameters

Name	Type	Description
r	FORTRAN: INTEGER, INTENT (OUT) C: int*	Vector of n random values with negative binomial distribution.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator ([RegisterBrng](#)) and for obtaining properties of the previously registered basic generators ([GetBrngProperties](#)). See [VSL Notes](#) ("Basic Generators" section of VSL Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator. This structure is described in Fortran as follows:

```

TYPE VSL_BRNG_PROPERTIES
    INTEGER streamstatesize
    INTEGER nseeds
    INTEGER includeszero
    INTEGER wordsize
    INTEGER nbits
    INTEGER nitstream
    INTEGER sbrng
    INTEGER dbrng
    INTEGER ibrng
END TYPE VSL_BRNG_PROPERTIES
    
```

The C version is as follows:

```

typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
    int IncludesZero;
    int WordSize;
    int NBits;
    InitStreamPtr InitStream;
    sBRngPtr sBRng;
    dBRngPtr dBRng;
    iBRngPtr iBRng;
} VSLBRngProperties;
    
```

The following table provides brief descriptions of the fields engaged in the above structure:

Table 10-13 Field Descriptions

Field	Short Description
FORTTRAN: streamstatesize C: StreamStateSize	The size, in bytes, of the stream state structure for a given basic generator.
FORTTRAN: nseeds C: NSeeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
FORTTRAN: includeszero C: IncludesZero	Flag value indicating whether the generator can produce a random 0.
FORTTRAN: wordsize C: WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
FORTTRAN: nbits C: NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, wordsize/WordSize is equal to 8 (number of bytes used to store the random value), while nbits/NBits contains the actual number of bits occupied by the value (in this example, 48).
FORTTRAN: initstream C: InitStream	Contains the pointer to the initialization routine of a given basic generator.
FORTTRAN: sbrng C: sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (<i>a</i> , <i>b</i>) (real in FORTRAN and float in C).
FORTTRAN: dbrng C: dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (<i>a</i> , <i>b</i>) (double PRECISION in FORTRAN and double in C).
FORTTRAN: ibrng C: iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution ¹ (INTEGER in FORTRAN and unsigned int in C).

¹A specific generator that permits operations over single bits and bit groups of random numbers.

RegisterBrng

Registers user-defined basic generator.

Syntax

Fortran:

```
brng = vslregisterbrng( properties )
```

C:

```
brng = vslRegisterBrng( &properties );
```

Description

An example of a registration procedure can be found in the respective directory of VSL examples.

Input Parameters

Name	Type	Description
<i>properties</i>	FORTTRAN: TYPE (VSL_BRNG_PROPERTIES), INTENT (IN) C: VSLBRngProperties*	Pointer to the structure containing properties of the basic generator to be registered

Output Parameters

Name	Type	Description
<i>brng</i>	FORTTRAN: INTEGER, INTENT (OUT) C: int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_ERROR_BAD_STREAM_STATE_SIZE	Bad value in StreamStateSize field.

VSL_ERROR_BAD_WORD_SIZE	Bad value in <code>WordSize</code> field.
VSL_ERROR_BAD_NSEEDS	Bad value in <code>NSeeds</code> field.
VSL_ERROR_BAD_NBITS	Bad value in <code>NBits</code> field.
VSL_ERROR_NULL_PTR	At least one of the fields <code>iBrng</code> , <code>dBrng</code> , <code>sBrng</code> or <code>InitStream</code> is a <code>NULL</code> pointer.

GetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

Fortran:

```
status = vslgetbrngproperties( brng, properties )
```

C:

```
status = vslGetBrngProperties( brng, &properties );
```

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN: INTEGER, INTENT (IN) C: int	Number (index) of the registered basic generator; used for identification. See specific values in Table 10-2 . Negative values indicate the registration error.

Output Parameters

Name	Type	Description
<i>properties</i>	FORTRAN: TYPE (VSL_BRNG_PROPERTIES), INTENT (OUT) C: VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using [RegisterBrng](#) function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See below recommendations on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VSL examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned
int params[] );

typedef int(*sBrngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );

typedef int(*dBrngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );

typedef int(*iBrngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

C:

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int
params[] )
{
    /* Initialize the stream */

    ...

} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_ERROR_SKIPAHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of [LeapfrogStream](#) and [SkipAheadStream](#), respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

C:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;

- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in $LCG(a, c, m)$, apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k - 1) c / (a - 1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VSL examples.

iBrng

C:

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
       store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE. When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector r correctly. For example, storing one 64-bit value requires two elements of r , the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of r to store a 128-bit value.

sBRng

C:

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i;    /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dBRng

C:

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i;    /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */
```

Convolution and Correlation

Overview

VSL provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision data.

For correct definition of implemented operations, see [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision data
- Fourier algorithms for multi-dimensional single and double precision data
- Direct algorithms for one-dimensional single and double precision data.
- Direct algorithms for multi-dimensional single and double precision data.

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

SCONF, SCORF

SCOND, SCORD

SDCON, SDCOR

DDCON, DDCOR

SDDCON, SDDCOR.

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources for FORTRAN and C. To reuse them, use the following directories:

```
${MKL}/examples/vslc/essl/vsl_wrappers
```

```
${MKL}/examples/vslf/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers. You can find the examples in the following directories:

```
${MKL}/examples/vslc/essl
```

```
${MKL}/examples/vslf/essl
```

Convolution and correlation API provides interfaces for Fortran 90 and C/89 languages. You may use the C/89 interface also with later versions of C or C++, or Fortran 90 interface with programs written in Fortran 95. Note that there is no Fortran 77 support.

For users of the C/C++ and FORTRAN languages, the `mkl_vsl.h` and `mkl_vsl.fi` headers are provided. Both header files are found under the directory:

```
${MKL}/include
```

See more details about the FORTRAN header in [Random Number Generators](#) section of this chapter.

Convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All Intel MKL convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of FORTRAN routines in the convolution and correlation API are written in lowercase, while the names of FORTRAN types and constants are written in uppercase. The names are not case-sensitive.

In C, the names of routines, types, and constants are case-sensitive and can be lowercase and uppercase.

The names of routines have the following structure:

`vsl[datatype]{Conv|Corr}<base name>` for C-interface

`vsl[datatype]{conv|corr}<base name>` for FORTRAN-interface

where `vsl` is a prefix indicating that the routine belongs to Vector Statistical Library of Intel® MKL.

The field `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be either `s` (for single precision real type) or `d` (for double precision real type).

The prefix `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.

The `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

NOTE. In this document, routines are often referred to by their base name when this does not lead to ambiguity. In the routine reference, the full name is always used in prototypes and code examples.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTTRAN: <code>TYPE (VSL_CONV_TASK)</code> C: <code>VSLConvTaskPtr</code>	Pointer to a task descriptor for convolution
FORTTRAN: <code>TYPE (VSL_CORR_TASK)</code> C: <code>VSLCorrTaskPtr</code>	Pointer to a task descriptor for correlation
FORTTRAN: <code>REAL (KIND=4)</code> C: <code>float</code>	Input/output user data in single precision
FORTTRAN: <code>REAL (KIND=8)</code>	Input/output user data in double precision

Type	Data Object
C: double	
FORTRAN: INTEGER	All other data
C: int	

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE. The actual size of the generic integer type is platform-dependent. The appropriate byte size for integers must be chosen at the stage of compiling your software.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Table 10-14 Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<i>job</i>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x</i> , <i>y</i> , <i>z</i> .

Name	Category	Type	Default Value Label	Description
<i>kind</i>	optional	integer	"linear"	Specifies whether the task relates to computing linear or circular convolution/correlation
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x</i> , <i>y</i> , <i>z</i> . Can be in the range from 1 to 7.
<i>x,y</i>	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
<i>z</i>	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
<i>xshape, yshape, zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x</i> , <i>y</i> , <i>z</i> . See Data Allocation for more information.

Name	Category	Type	Default Value Label	Description
<i>xstride, ystride, zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x</i> , <i>y</i> , <i>z</i> , that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See SetStart and Data Allocation for more information.
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See SetDecimation and Data Allocation for more information.

Users of the C or C++ language may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the FORTRAN-style “by columns” representation of multi-dimensional arrays.

Task Status and Error Reporting

Task status is an integer value which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values are used for errors, and positive values are reserved for warnings.

An error can be caused by bad parameter values, system fault like memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors of executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation which is implicitly invoked before task execution or task copying. If an error is detected

at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor will be terminated and the task will keep the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The status codes are given symbolic names defined in the respective header files. For C/C++, these names are defined as macros via `#define` statements, and for FORTRAN as integer constants via `PARAMETER` operators.

If there is no error, the `VSL_STATUS_OK` is returned, which is defined as zero:

```
C/C++:          #define, VSL_STATUS_OK 0
F90/F95:        INTEGER, PARAMETER:: VSL_STATUS_OK = 0
```

In case of an error, a non-zero error code is returned, which signals about the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files for both C/C++ and FORTRAN languages.

Table 10-15 Convolution/Correlation Status Codes and Messages

Status Code	Message
<code>VSL_CC_ERROR_NOT_IMPLEMENTED,</code>	Requested functionality is not implemented.
<code>VSL_CC_ERROR_ALLOCATION_FAILURE</code>	Memory allocation failure.
<code>VSL_CC_ERROR_BAD_DESCRIPTOR</code>	Task descriptor is corrupted.
<code>VSL_CC_ERROR_SERVICE_FAILURE</code>	A service function has failed.
<code>VSL_CC_ERROR_EDIT_FAILURE</code>	Failure while editing the task.
<code>VSL_CC_ERROR_EDIT_PROHIBITED</code>	You cannot edit this parameter.
<code>VSL_CC_ERROR_COMMIT_FAILURE</code>	Task commitment has failed.
<code>VSL_CC_ERROR_COPY_FAILURE</code>	Failure while copying the task.
<code>VSL_CC_ERROR_DELETE_FAILURE</code>	Failure while deleting the task.
<code>VSL_CC_ERROR_BAD_ARGUMENT</code>	Bad argument or task parameter.
<code>VSL_CC_ERROR_JOB</code>	Bad parameter: <i>job</i> .
<code>SL_CC_ERROR_KIND</code>	Bad parameter: <i>kind</i> .

Status Code	Message
VSL_CC_ERROR_MODE	Bad parameter: <i>mode</i> .
VSL_CC_ERROR_METHOD	Bad parameter: <i>method</i> .
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> .
	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_CC_ERROR_ZSHAPE	Bad parameter: <i>zshape</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .
VSL_CC_ERROR_OTHER	Some other error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. This means that no additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form but also assign particular data to the first operand vector used in convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

For each constructor routine there is also an associated one-dimensional version which exploits the algorithmic and computational benefits provided by the simplicity of the data structures for one-dimensional case.

NOTE. If constructor fails to create a task descriptor, it returns `NULL` task pointer.

The [Table 10-16](#) lists available task constructors:

Table 10-16 Task Constructors

Routine	Description
NewTask	Creates a new convolution or correlation task descriptor for a multidimensional case.
NewTask1D	Creates a new convolution or correlation task descriptor for a one-dimensional case.
NewTaskX	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
NewTaskX1D	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

NewTask

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslscorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

Description

Each `NewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

If constructor fails to create a task descriptor, it returns `NULL` task pointer.

Input Parameters

Name	Type	Description
<i>mode</i>	FORTTRAN: INTEGER C: int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>dims</i>	FORTTRAN: INTEGER C: int	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
<i>xshape</i>	FORTTRAN: INTEGER, DIMENSION(*) C: int[]	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTTRAN: INTEGER, DIMENSION(*) C: int[]	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTTRAN: INTEGER, DIMENSION(*) C: int[]	Defines the shape of the output data to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE(VSL_CONV_TASK) for vslsconvnewtask, vsldconvnewtask TYPE(VSL_CORR_TASK) for vslscorrnewtask, vsldcorrnewtask	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	C: VSLConvTaskPtr* for vslsConvNewTask, vsldConvNewTask VSLCorrTaskPtr* for vslsCorrNewTask, vsldCorrNewTask	
<i>status</i>	FORTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

NewTask1D

*Creates a new convolution or correlation task
descriptor for one-dimensional case.*

Syntax

Fortran:

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslsCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Description

Each `NewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)). Unlike `NewTask`, these routines represent a special one-dimensional

version of the constructor which assumes that the value of the parameter *dims* is 1. The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

Input Parameters

Name	Type	Description
<i>mode</i>	FORTTRAN: INTEGER C: int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.
<i>xshape</i>	FORTTRAN: INTEGER C: int	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTTRAN: INTEGER C: int	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTTRAN: INTEGER C: int	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE(VSL_CONV_TASK) for vslsconvnewtaskld, vsldconvnewtaskld TYPE(VSL_CORR_TASK) for vslscorrnewtaskld, vsldcorrnewtaskld	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	C: VSLConvTaskPtr* for vslsConvNewTask1D, vsldConvNewTask1D VSLCorrTaskPtr* for vslsCorrNewTask1D, vsldCorrNewTask1D	
<i>status</i>	FORTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

NewTaskX

*Creates a new convolution or correlation task
descriptor for multidimensional case and assigns
source data to the first operand vector.*

Syntax

Fortran:

```
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslscorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vsldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);

status = vsldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x,
xstride);
```

Description

Each `NewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

Unlike `NewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `NewTaskX` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see `DeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

The stride parameter `xstride` specifies the physical location of the input data in the array `x`. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every s^{th} element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

Input Parameters

Name	Type	Description
<code>mode</code>	FORTAN: INTEGER C: <code>int</code>	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.

Name	Type	Description
<i>dims</i>	FORTRAN: INTEGER C: int	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
<i>xshape</i>	FORTRAN: INTEGER, DIMENSION (*) C: int[]	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTRAN: INTEGER, DIMENSION (*) C: int[]	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTRAN: INTEGER, DIMENSION (*) C: int[]	Defines the shape of the output data to be stored in array <i>z</i> .See Data Allocation for more information.
<i>x</i>	FORTRAN: REAL (KIND=4) , DIMENSION (*) for single precision flavors, REAL (KIND=8) , DIMENSION (*) for double precision flavors C: float[] for single precision flavors double[] for double precision flavors	Pointer to the array containing input data for the first operand vector.See Data Allocation for more information.
<i>xstride</i>	FORTRAN: INTEGER, DIMENSION (*) C: int[]	Strides for input data in the array <i>x</i> .

Output Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE(VSL_CONV_TASK) for vslsconvnewtaskx, vsldconvnewtaskx TYPE(VSL_CORR_TASK) for vslscorrnewtaskx, vsldcorrnewtaskx C: VSLConvTaskPtr* for vslsConvNewTaskX, vsldConvNewTaskX VSLCorrTaskPtr* for vslsCorrNewTaskX, vsldCorrNewTaskX	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	FORTTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

NewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

```
status = vsldconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

```
status = vslscorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

```
status = vsldcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

Description

Each `NewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table 10-14](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter `dims` is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `NewTaskX1D` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [DeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

The [stride parameters](#) `xstride` specifies the physical location of the input data in the array `x` and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every s^{th} element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

Input Parameters

Name	Type	Description
<code>mode</code>	FORTRAN: INTEGER C: int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table 10-18 for a list of possible values.

Name	Type	Description
<i>xshape</i>	FORTTRAN: INTEGER C: int	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	FORTTRAN: INTEGER C: int	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	FORTTRAN: INTEGER C: int	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.
<i>x</i>	FORTTRAN: REAL (KIND=4) , DIMENSION (*) for single precision flavors, REAL (KIND=8) , DIMENSION (*) for double precision flavors C: float[] for single precision flavors double[] for double precision flavors	Pointer to the array containing input data for the first operand vector. See Data Allocation for more information.
<i>xstride</i>	FORTTRAN: INTEGER C: int	Stride for input data sequence in the array <i>x</i> .

Output Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE (VSL_CONV_TASK) for vslsconvnewtaskxld, vsldconvnewtaskxld	Pointer to the task descriptor if created successfully or NULL pointer otherwise.

Name	Type	Description
	TYPE (VSL_CORR_TASK) for vslscorrnewtaskxld, vsldcorrnewtaskxld C: VSLConvTaskPtr* for vslsConvNewTaskXlD, vsldConvNewTaskXlD VSLCorrTaskPtr* for vslsCorrNewTaskXlD, vsldCorrNewTaskXlD	
<i>status</i>	FORTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Task Editors

Task editors in convolution and correlation API of the Intel MKL are routines intended for setting up or changing the following task parameters (see [Table 10-14](#)):

- *mode*
- *internal_precision*
- *start*
- *decimation.*

For setting up or changing each of the above parameters, a separate routine exists.

NOTE. Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

After applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and will go through the full commitment process again during the next execution or copy operation. This is motivated by the fact that the currently stored work data computed during the last commitment process may become invalid with respect to new parameter settings. For more information about task commitment, see [Overview](#).

[Table 10-17](#) lists available task editors.

Table 10-17 Task Editors

Routine	Description
<code>SetMode</code>	Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.
<code>SetInternalPrecision</code>	Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation.
<code>SetStart</code>	Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.
<code>SetDecimation</code>	Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.

NOTE. You can use the `NULL` task pointer in calls to editor routines. In this case, the routine will be terminated and no system crash will occur.

SetMode

Changes the value of the parameter `mode` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetmode(task, newmode)
status = vslcorrsetmode(task, newmode)
```

C:

```
status = vslConvSetMode(task, newmode);
status = vslCorrSetMode(task, newmode);
```

Description

The routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

Table 10-18 Values of `mode` parameter

Value	Purpose
VSL_CONV_MODE_FFT	Compute convolution by using fast Fourier transform.
VSL_CORR_MODE_FFT	Compute correlation by using fast Fourier transform.
VSL_CONV_MODE_DIRECT	Compute convolution directly.
VSL_CORR_MODE_DIRECT	Compute correlation directly.
VSL_CONV_MODE_AUTO	Automatically choose direct or Fourier mode for convolution.
VSL_CORR_MODE_AUTO	Automatically choose direct or Fourier mode for correlation.

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN: TYPE (VSL_CONV_TASK) for vslconvsetmode TYPE (VSL_CORR_TASK) for vslcorrsetmode C: VSLConvTaskPtr for vslConvSetMode VSLCorrTaskPtr for vslCorrSetMode	Pointer to the task descriptor.
<i>newmode</i>	FORTRAN: INTEGER C: int	New value of the parameter <code>mode</code> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTTRAN: INTEGER C: int	Current status of the task.

SetInternalPrecision

Changes the value of the parameter `internal_precision` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetinternalprecision(task, precision)  
status = vslcorrsetinternalprecision(task, precision)
```

C:

```
status = vslConvSetInternalPrecision(task, precision);  
status = vslCorrSetInternalPrecision(task, precision);
```

Description

The routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either “single” or “double” according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was “single” but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Table 10-19 Values of *internal_precision* Parameter

Value	Purpose
VSL_CONV_PRECISION_SINGLE	Compute convolution with single precision.
VSL_CORR_PRECISION_SINGLE	Compute correlation with single precision.
VSL_CONV_PRECISION_DOUBLE	Compute convolution with double precision.
VSL_CORR_PRECISION_DOUBLE	Compute correlation with double precision.

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN: TYPE(VSL_CONV_TASK) for vslconvsetinternalprecision TYPE(VSL_CORR_TASK) for vslcorrsetinternalprecision C: VSLConvTaskPtr for vslConvSetInternalPrecision VSLCorrTaskPtr for vslCorrSetInternalPrecision	Pointer to the task descriptor.
<i>precision</i>	FORTRAN: INTEGER C: int	New value of the parameter <i>internal_precision</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN: INTEGER C: int	Current status of the task.

SetStart

Changes the value of the parameter `start` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetstart(task, start)
```

```
status = vslcorrsetstart(task, start)
```

C:

```
status = vslConvSetStart(task, start);
```

```
status = vslCorrSetStart(task, start);
```

Description

The routine sets the value of the parameter `start` for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, `start` is an array of indices and its length is equal to the number of dimensions specified by the parameter `dims`. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for `start` is undefined and this parameter is not used. Hence, the only way to set and use the `start` parameter is via assigning it some value by one of the `SetStart` routines.

Input Parameters

Name	Type	Description
<code>task</code>	FORTTRAN: TYPE(VSL_CONV_TASK) for vslconvsetstart TYPE(VSL_CORR_TASK) for vslcorrsetstart C: VSLConvTaskPtr for vslConvSetStart	Pointer to the task descriptor.

Name	Type	Description
	VSLCorrTaskPtr for vslCorrSetStart	
<i>start</i>	FORTRAN: INTEGER, DIMENSION (*) C: int[]	New value of the parameter <i>start</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN: INTEGER C: int	Current status of the task.

SetDecimation

Changes the value of the parameter `decimation` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetdecimation(task, decimation)
status = vslcorrsetdecimation(task, decimation)
```

C:

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Description

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation.

This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if *decimation* = *d* > 1, only every *d*-th element of the mathematical result is written to the output

array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Hence, the only way to set and use the *decimation* parameter is via assigning it some value by one of the `SetDecimation` routines.

Input Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE(VSL_CONV_TASK) for vslconvsetdecimation TYPE(VSL_CORR_TASK) for vslcorrsetdecimation C: VSLConvTaskPtr for vslConvSetDecimation VSLCorrTaskPtr for vslCorrSetDecimation	Pointer to the task descriptor.
<i>decimation</i>	FORTTRAN: INTEGER, DIMENSION (*) C: int[]	New value of the parameter <i>decimation</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTTRAN: INTEGER C: int	Current status of the task.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the supplied user data for input vectors.

Once created and adjusted, the task can be executed multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL implementation of the convolution and correlation API provides two different forms of execution routines: a general form and an X-form. General form executors use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input. Alternatively, X-form executors use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage.

When the task is executed for the first time, the execution routine includes task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

For each execution routine there is also an associated one-dimensional version which exploits the algorithmic and computational benefits provided by the simplicity of the data structures for one-dimensional case.

NOTE. You can use the `NULL` task pointer in calls to execution routines. In this case, the routine will be terminated and no system crash will occur.

If the task is executed successfully, the execution routine returns zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`,
- if the task descriptor is corrupted,
- if calculation has failed for some other reason.

NOTE. Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Table 10-20 Task Execution Routines

Routine	Description
<code>Exec</code>	Computes convolution or correlation for a multidimensional case.
<code>Exec1D</code>	Computes convolution or correlation for a one-dimensional case.

Routine	Description
ExecX	Computes convolution or correlation as X-form for a multidimensional case.
ExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

Exec

Computes convolution or correlation for multidimensional case.

Syntax

Fortran:

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
```

Description

Each of the `Exec` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTask` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

The stride parameters `xstride`, `ystride`, and `zstride` specify the physical location of the input and output data in the arrays `x`, `y`, and `z`, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `zstride` is `s`, then only every s^{th} element of the array `z` will be used to store the output data. The stride value must be positive or negative but not zero.

Input Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE (VSL_CONV_TASK) for vslsconvexec and vsldconvexec TYPE (VSL_CORR_TASK) for vslscorrexec and vsldcorrexec C: VSLConvTaskPtr for vslsConvExec and vsldConvExec VSLCorrTaskPtr for vslsCorrExec and vsldCorrExec	Pointer to the task descriptor.
<i>x, y</i>	FORTTRAN: REAL (KIND=4) , DIMENSION (*) for vslsconvexec and vslscorrexec REAL (KIND=8) , DIMENSION (*) for vsldconvexec and vsldcorrexec C: float[] for vslsConvExec and vslsCorrExec double[] for vsldConvExec and vsldCorrExec	Pointers to arrays containing input data. See Data Allocation for more information.
<i>xstride, ystride, zstride</i>	FORTTRAN: INTEGER, DIMENSION (*) C: int[]	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	FORTTRAN: REAL(KIND=4) , DIMENSION(*) for vslsconvexec and vslscorexec REAL(KIND=8) , DIMENSION(*) for vsldconvexec and vsldcorexec C: float[] for vslsConvExec and vslsCorrExec double[] for vsldConvExec and vsldCorrExec	Pointer to the array that stores output data. See Data Allocation for more information.
<i>status</i>	FORTTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Exec1D

Computes convolution or correlation for one-dimensional case.

Syntax

Fortran:

```

status = vslsconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslscorexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldcorexec1d(task, x, xstride, y, ystride, z, zstride)

```

C:

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

Description

Each of the `Exec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTask1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

Input Parameters

Name	Type	Description
<code>task</code>	FORTRAN: TYPE (VSL_CONV_TASK) for vslsconvexec1d and vsldconvexec1d TYPE (VSL_CORR_TASK) for vslscorexec1d and vsldcorexec1d C: VSLConvTaskPtr for vslsConvExec1D and vsldConvExec1D VSLCorrTaskPtr for vslsCorrExec1D and vsldCorrExec1D	Pointer to the task descriptor.

Name	Type	Description
<i>x, y</i>	FORTTRAN: REAL(KIND=4) , DIMENSION(*) for vslsconvexecld and vslscorexecld REAL(KIND=8) , DIMENSION(*) for vsldconvexecld and vsldcorexecld C: float[] for vslsConvExec1D and vslsCorrExec1D double[] for vsldConvExe1D and vsldCorrExec1D	Pointers to arrays containing input data. See Data Allocation for more information.
<i>xstride, ystride, zstride</i>	FORTTRAN: INTEGER C: int	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	FORTTRAN: REAL(KIND=4) , DIMENSION(*) for vslsconvexecld and vslscorexecld REAL(KIND=8) , DIMENSION(*) for vsldconvexecld and vsldcorexecld C: float[] for vslsConvExec1D and vslsCorrExec1D	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	double[] for vsldConvExec1D and vsldCorrExec1D	
<i>status</i>	FORTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

ExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexec(task, y, ystride, z, zstride)
status = vsldconvexec(task, y, ystride, z, zstride)
status = vslscorrexec(task, y, ystride, z, zstride)
status = vsldcorrexec(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);
```

Description

Each of the ExecX routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array *x*.

Parameters of the operation are read from the task descriptor created previously by a corresponding [NewTaskX](#) constructor and pointed to by *task*. If *task* is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Input Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE(VSL_CONV_TASK) for vslsconvexecx and vsldconvexecx TYPE(VSL_CORR_TASK) for vslscorreexecx and vsldcorreexecx C: VSLConvTaskPtr for vslsConvExecX and vsldConvExecX VSLCorrTaskPtr for vslsCorrExecX and vsldCorrExecX	Pointer to the task descriptor.
<i>x ,y</i>	FORTTRAN: REAL(KIND=4) , DIMENSION(*) for vslsconvexecx and vslscorreexecx REAL(KIND=8) , DIMENSION(*) for vsldconvexecx and vsldcorreexecx C: float[] for vslsConvExecX and vslsCorrExecX	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	double[] for vsldConvExeX and vsldCorrExecX	
<i>ystride</i> <i>,zstride</i>	FORTTRAN: INTEGER, DIMENSION(*) C: int[]	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	FORTTRAN: REAL(KIND=4) , DIMENSION(*) for vslsconvexecx and vsldcorrexecx REAL(KIND=8) , DIMENSION(*) for vsldconvexecx and vsldcorrexecx C: float[] for vsldConvExecX and vsldCorrExecX double[] for vsldConvExecX and vsldCorrExecX	Pointer to the array that stores output data. See Data Allocation for more information.
<i>status</i>	FORTTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

ExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx1d(task, y, ystride, z, zstride)
status = vsldconvexecx1d(task, y, ystride, z, zstride)
status = vslscorrexx1d(task, y, ystride, z, zstride)
status = vsldcorrexx1d(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX1D(task, y, ystride, z, zstride);
status = vsldConvExecX1D(task, y, ystride, z, zstride);
status = vslsCorrExecX1D(task, y, ystride, z, zstride);
status = vsldCorrExecX1D(task, y, ystride, z, zstride);
```

Description

Each of the `ExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `NewTaskX1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Input Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE (VSL_CONV_TASK) for vslsconvexecx1d and vsldconvexecx1d TYPE (VSL_CORR_TASK) for vslscorrexecx1d and vsldcorrexecx1d C: VSLConvTaskPtr for vslsConvExecX1D and vsldConvExecX1D VSLCorrTaskPtr for vslsCorrExecX1D and vsldCorrExecX1D	Pointer to the task descriptor.
<i>x, y</i>	FORTTRAN: REAL (KIND=4) , DIMENSION (*) for vslsconvexecx1d and vslscorrexecx1d REAL (KIND=8) , DIMENSION (*) for vsldconvexecx1d and vsldcorrexecx1d C: float[] for vslsConvExecX1D and vslsCorrExecX1D double[] for vsldConvExeX1D and vsldCorrExecX1D	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.
<i>ystride, zstride</i>	FORTTRAN: INTEGER C: int	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	FORTTRAN: REAL (KIND=4) , DIMENSION(*) for vslsconvexecx1d and vslscorreexecx1d REAL (KIND=8) , DIMENSION(*) for vsldconvexecx1d and vsldcorreexec1d C: float[] for vslsConvExecX1D and vslsCorrExecX1D double[] for vsldConvExecX1D and vsldCorrExecX1D	Pointer to the array that stores output data. See Data Allocation for more information.
<i>status</i>	FORTTRAN: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

DeleteTask

Destroys the task object and frees the memory.

Syntax

Fortran:

```
errcode = vslconvdeletetask(task)
errcode = vslcorrdeletetask(task)
```

C:

```
errcode = vslConvDeleteTask(task);  
errcode = vslCorrDeleteTask(task);
```

Description

Given a pointer to a task descriptor, this routine deletes the task descriptor object and frees the memory allocated for the data structure. If the task holds a work memory, the latter is also freed. The task pointer is set to `NULL`.

Note that if by some reason the task was not deleted successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE. You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine will be terminated and no system crash will occur.

Input Parameters

Name	Type	Description
<i>task</i>	FORTTRAN: TYPE (VSL_CONV_TASK) for vslconvdeletetask TYPE (VSL_CORR_TASK) for vslcorrdeletetask C: VSLConvTaskPtr* for vslConvDeleteTask VSLCorrTaskPtr* for vslCorrDeleteTask	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
<i>errcode</i>	FORTTRAN: INTEGER C: int	Contains 0 if the task object is deleted successfully. Contains error code if an error occurred.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

CopyTask

Copies a descriptor for convolution or correlation task.

Syntax

Fortran:

```
status = vslconvcopytask(newtask, srctask)
```

```
status = vslcorrcopytask(newtask, srctask)
```

C:

```
status = vslConvCopyTask(newtask, srctask);
```

```
status = vslCorrCopyTask(newtask, srctask);
```

Description

If a task object *srctask* already exists, you can use an appropriate *CopyTask* routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Overview](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

Input Parameters

Name	Type	Description
<i>srctask</i>	FORTTRAN: <code>TYPE(VSL_CONV_TASK)</code> for <code>vslconvcopytask</code> <code>TYPE(VSL_CORR_TASK)</code> for <code>vslcorrcopytask</code>	Pointer to the source task descriptor.

Name	Type	Description
	C: VSLConvTaskPtr for vslConvCopyTask	
	VSLCorrTaskPtr for vslCorrCopyTask	

Output Parameters

Name	Type	Description
<i>newtask</i>	FORTTRAN: TYPE (VSL_CONV_TASK) for vslconvcopytask TYPE (VSL_CORR_TASK) for vslcorrcopytask C: VSLConvTaskPtr* for vslConvCopyTask VSLCorrTaskPtr* for vslCorrCopyTask	Pointer to the new task descriptor.
<i>status</i>	FORTTRAN: INTEGER C: int	Current status of the source task.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single threaded and multiple threaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single threaded calculations and can be used with C or C++ compilers.

Example 10-5 Function `scond1` for Single Threaded Calculations

```
#include "mkl_vsl.h"

int scont1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task, VSL_CONV_MODE_DIRECT, nh, nx, ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h, inch, x, incx, y, incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Example 10-6 Function `sconf1` for Single Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inclh,
    float x[], int inclx, int inc2x,
    float y[], int incly, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;

    /* assume that aux1!=0 and naux1 is big enough */
```

```

VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
if (init != 0)
    /* initialization: */
    status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
        nh, nx, ny, h, inclh);
if (init == 0) {
    /* calculations: */
    int i;
    vslConvSetStart(*task, &iy0);
    for (i=0; i<m; i++) {
        float* xi = &x[inc2x * i];
        float* yi = &y[inc2y * i];
        /* task is implicitly committed at i==0 */
        status = vslsConvExecX1D(*task, xi, inclx, yi, incly);
    };
};
vslConvDeleteTask(task);
return status;
}

```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If `m>1`, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create `m` copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code for that can look like following:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
```

Then, *m* threads may be started to execute different copies of the task:

```
. . .
    float* xi = &x[inc2x * i];
    float* yi = &y[inc2y * i];
    ss[i]=vs1sConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
    . . .
```

And finally, after all threads have finished the calculations, overall status ought to be collected from all task objects. The following code assumes signaling the first error found, if any:

```
. . .
for (i=0; i<m; i++) {
    status = ss[i];
    if (status != 0) /* 0 means "OK" */
        break;
};
return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. This is the reason why different threads must use different copies of the task.

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$	The set of N-dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbf{Z}^N$	N-dimensional series of integers.
$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from $\mathbf{Z}^N$ and values from $\mathbf{R}$.
$u(p) = u(p_1, \dots, p_N)$	The value of the function u for the argument $(p_1, \dots, p_N)$.
$w = u * v$	Function w is the convolution of the functions u, v .
$w = u \bullet v$	Function w is the correlation of the functions u, v .

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1, \dots, N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1, \dots, N$
- series $r = \sup\{p, q\}$ is defines as $r^n = \max\{p^n, q^n\}$ for every $n=1, \dots, N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1, \dots, N$
- inequality $p \leq q$ means that $p^n \leq q^n$ for every $n=1, \dots, N$.

A function $u(p)$ is called a finite function if there exist series $p^{\min}, p^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$p^{\min} \leq p \leq p^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series $p^{\min}, p^{\max}, q^{\min}, q^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0 \text{ implies } p^{\min} \leq p \leq p^{\max}.$$

$v(q) \neq 0$ implies $Q^{\min} \leq q \leq Q^{\max}$.

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u * v$ is the convolution of u and v , then:

$w(r) \neq 0$ implies $R^{\min} \leq r \leq R^{\max}$,

where $R^{\min} = P^{\min} + Q^{\min}$ and $R^{\max} = P^{\max} + Q^{\max}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r-t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{\min} \leq t \leq T^{\max}$,

where $T^{\min} = \sup\{P^{\min}, r - Q^{\max}\}$ and $T^{\max} = \inf\{P^{\max}, r - Q^{\min}\}$.

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v , then:

$w(r) \neq 0$ implies $R^{\min} \leq r \leq R^{\max}$,

where $R^{\min} = Q^{\min} - P^{\max}$ and $R^{\max} = Q^{\max} - P^{\min}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r+t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{\min} \leq t \leq T^{\max}$,

where $T^{\min} = \sup\{P^{\min}, Q^{\min} - r\}$ and $T^{\max} = \inf\{P^{\max}, Q^{\max} - r\}$.

Representation of the functions u , v , w as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u , v , w introduced in the section [Mathematical Notation and Definitions](#);

- multi-dimensional input and output data vectors representing the functions u , v , w ;
- arrays u , v , w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x , y , z
- Shape arrays $xshape$, $yshape$, $zshape$
- Strides within arrays $xstride$, $ystride$, $zstride$
- Parameters $start$, $decimation$

Finite Functions and Data Vectors

The finite functions $u(p)$, $v(q)$, and $w(r)$ introduced above are represented as multi-dimensional vectors of input and output data:

`inputu(i1, ..., idims) for u(p1, ..., pN)`

`inputv(j1, ..., jdims) for v(q1, ..., qN)`

`output(k1, ..., kdims) for w(r1, ..., rN)`.

Parameter *dims* represents the number of dimensions and is equal to N .

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

`inputu(i1, ..., idims)` is defined if $1 \leq i_n \leq xshape(n)$ for every $n=1, \dots, dims$

`inputv(j1, ..., jdims)` is defined if $1 \leq j_n \leq yshape(n)$ for every $n=1, \dots, dims$

`output(k1, ..., kdims)` is defined if $1 \leq k_n \leq zshape(n)$ for every $n=1, \dots, dims$.

Relation between the input vectors and the functions u and v is defined by the following formulas:

`inputu(i1, ..., idims) = u(p1, ..., pN)`, where $p_n = p_n^{\min} + (i_n - 1)$ for every n

`inputv(j1, ..., jdims) = v(q1, ..., qN)`, where $q_n = q_n^{\min} + (j_n - 1)$ for every n .

Relation between the output vector and the function $w(r)$ is similar (but only in the case when parameters *start* and *decimation* are not defined):

`output(k1, ..., kdims) = w(r1, ..., rN)`, where $r_n = r_n^{\min} + (k_n - 1)$ for every n .

If the parameter *start* is defined, it must belong to the interval $R_n^{\min} \leq start(n) \leq R_n^{\max}$.

If defined, the *start* parameter replaces $R^{\min}$ in the formula:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = \text{start}(n) + (k_n - 1)$

If the parameter *decimation* is defined, it changes the relation according to the following formula:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = R_n^{\min} + (k_n - 1) \cdot \text{decimation}(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

$\text{output}(k_1, \dots, k_{\text{dims}}) = w(r_1, \dots, r_N)$, where $r_n = \text{start}(n) + (k_n - 1) \cdot \text{decimation}(n)$

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If r_n exceeds $R_n^{\max}$ for some $k_n, n=1, \dots, \text{dims}$, an error is raised.

Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

$\text{inputu}(i_1, \dots, i_{\text{dims}})$ is allocated at $x(e)$

$\text{inputv}(j_1, \dots, j_{\text{dims}})$ is allocated at $y(f)$

$\text{output}(k_1, \dots, k_{\text{dims}})$ is allocated at $z(g)$.

The indices *e*, *f*, and *g* are defined as follows:

$e = 1 + \sum x_{\text{stride}}(n) \cdot dx(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$f = 1 + \sum y_{\text{stride}}(n) \cdot dy(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$g = 1 + \sum z_{\text{stride}}(n) \cdot dz(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

The distances $dx(n)$, $dy(n)$, and $dz(n)$ depend on the signum of the stride:

$dx(n) = i_n - 1$ if $x_{\text{stride}}(n) > 0$, or $dx(n) = i_n - x_{\text{shape}}(n)$ if $x_{\text{stride}}(n) < 0$

$dy(n) = j_n - 1$ if $y_{\text{stride}}(n) > 0$, or $dy(n) = j_n - y_{\text{shape}}(n)$ if $y_{\text{stride}}(n) < 0$

$dz(n) = k_n - 1$ if $zstride(n) > 0$, or $dz(n) = k_n - zshape(n)$ if $zstride(n) < 0$

The definitions of indices e , f , and g assume that indexes for arrays x , y , and z are started from unity:

$x(e)$ is defined for $e=1, \dots, \text{length}(x)$

$y(f)$ is defined for $f=1, \dots, \text{length}(y)$

$z(g)$ is defined for $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array z for one-dimensional and two-dimensional cases.

One-dimensional case. If $dims=1$, then $zshape$ is the number of the output values to be stored in the array z . The actual length of array z may be greater than $zshape$ elements.

If $zstride > 1$, output values are stored with the stride: $\text{output}(1)$ is stored to $z(1)$, $\text{output}(2)$ is stored to $z(1+zstride)$, and so on. Hence, the actual length of z must be at least $1+zstride*(zshape-1)$ elements or more.

If $zstride < 0$, it still defines the stride between elements of array z . However, the order of the used elements is the opposite. For the k -th output value, $\text{output}(k)$ is stored in $z(1+|zstride|*(zshape-k))$, where $|zstride|$ is the absolute value of $zstride$. The actual length of the array z must be at least $1+|zstride|*(zshape - 1)$ elements.

Two-dimensional case. If $dims=2$, the output data is a two-dimensional matrix. The value $zstride(1)$ defines the stride inside matrix columns, that is, the stride between the $\text{output}(k_1, k_2)$ and $\text{output}(k_1+1, k_2)$ for every pair of indices k_1, k_2 . On the other hand, $zstride(2)$ defines the stride between columns, that is, the stride between $\text{output}(k_1, k_2)$ and $\text{output}(k_1, k_2+1)$.

If $zstride(2)$ is greater than $zshape(1)$, this causes sparse allocation of columns. If the value of $zstride(2)$ is smaller than $zshape(1)$, this may result in the transposition of the output matrix. For example, if $zshape = (2, 3)$, you can define $zstride = (3, 1)$ to allocate output values like transposed matrix of the shape 3×2 .

Whether $zstride$ assumes this kind of transformations or not, you need to ensure that different elements $\text{output}(k_1, \dots, k_{dims})$ will be stored in different locations $z(g)$.

Fourier Transform Functions

This chapter describes the following implementations of the fast Fourier transform functions available in Intel® MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#) below)
- [Cluster FFT functions](#) for distributed-memory architectures (available with Intel® MKL for the Linux* and Windows* OSs only).

The general form of the discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \pm 1, \pm 2, \dots$, where σ is an arbitrary real-valued scale factor and $\delta = \pm 1$. The forward transform is defined by $\sigma = 1$ and $\delta = -1$. In most common situations, the domain of the forward transform, that is, the set where the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs, can be either the set of complex-valued sequences, real-valued sequences, and complex-valued conjugate even sequences.

Both groups of FFT functions above present a uniform and easy-to-use applications programmer interface providing fast computation of discrete Fourier transform via the fast Fourier transform algorithm.

The FFT functions support arbitrary lengths. See the *Intel MKL User's Guide* for the specific radices supported.

NOTE. The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide an efficient tool for conversion to and from the polar representation (see [Example C-30a in Appendix C](#) and [Example C-30b in Appendix C](#)).

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

Table 11-1 lists FFT functions implemented in Intel MKL:

Table 11-1 FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
<code>DftiCreateDescriptor</code>	Allocates memory for the descriptor data structure and preliminarily initializes it.
<code>DftiCommitDescriptor</code>	Performs all initialization for the actual FFT computation.
<code>DftiCopyDescriptor</code>	Copies an existing descriptor.
<code>DftiFreeDescriptor</code>	Frees memory allocated for a descriptor.
FFT Computation Functions	
<code>DftiComputeForward</code>	Computes the forward FFT.
<code>DftiComputeBackward</code>	Computes the backward FFT.
Descriptor Configuration Functions	
<code>DftiSetValue</code>	Sets one particular configuration parameter with the specified configuration value.
<code>DftiGetValue</code>	Gets the value of one particular configuration parameter.
Status Checking Functions	
<code>DftiErrorClass</code>	Checks if the status reflects an error of a predefined class.
<code>DftiErrorMessage</code>	Generates an error message.

Description of the FFT functions is followed by discussion of configuration settings (see [Configuration Settings](#)) and various configuration parameters used.

Computing FFT

The FFT functions described later in this chapter are provided with the Fortran and C interfaces. Fortran stands for Fortran 95. The FFT interface relies critically on many modern features offered in Fortran 95 that have no counterpart in FORTRAN 77

NOTE. Following the explicit function interface in Fortran, data array must be defined as one-dimensional for any transformation type.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

You can find code examples that use FFT interface functions to compute transform results in [Fourier Transform Functions Code Examples](#) section in the Appendix C.

For most common situations, an FFT computation can be effected by four function calls. The approach adopted in Intel MKL for FFT computation uses one single data structure, the descriptor, to record flexible configuration whose parameters can be changed independently. This results in enhanced functionality and ease of use.

The record of type `DFTI_DESCRIPTOR`, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of rather a large number of configuration parameters. The default settings for all of these parameters include, for example, the following:

- the FFT to be computed does not have a scale factor;
- there is only one set of data to be transformed;
- the data is stored contiguously in memory;
- the computed result overwrites (in place) the input data; etc.

Should any one of these many default settings be inappropriate, they can be changed one-at-a-time through the function `DftiSetValue` as illustrated in the [Example C-20](#) and [Example C-21](#).

FFT Interface

To use the FFT functions, you need to access the module `MKL_DFTI` through the "use" statement in Fortran; or access the header file `mkl_dfti.h` through "include" in C.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR`, a macro definition

```
#define DFTI_DESCRIPTOR_HANDLE DFTI_DESCRIPTOR *
```

a number of named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`; and a number of functions, some of which accept different number of input arguments.

NOTE. Some of the FFT functions and/or functionality described in the subsequent sections of this chapter may not be supported by the currently available implementation of the library. You can find the complete list of the implementation-specific exceptions in the release notes to your version of the library.

There are four main categories of FFT functions in Intel MKL:

- 1. Descriptor Manipulation.** There are four functions in this category. The first one, [DftiCreateDescriptor](#), creates an FFT descriptor whose storage is allocated dynamically. This function configures the descriptor with default settings corresponding to a few input values supplied by the user.

The second, [DftiCommitDescriptor](#), "commits" the descriptor to all its setting. In practice, this usually means that all the necessary precomputation will be performed. This may include factorization of the input length and computation of all the required twiddle factors. The third function, [DftiCopyDescriptor](#), makes an extra copy of a descriptor, and the fourth function, [DftiFreeDescriptor](#), frees up all the memory allocated for the descriptor information.
- 2. FFT Computation.** There are two functions in this category. The first, [DftiComputeForward](#), performs the forward FFT computation, and the second function, [DftiComputeBackward](#), performs a backward FFT computation.
- 3. Descriptor configuration.** There are two functions in this category. One function, [DftiSetValue](#), sets one specific value to one of the many configuration parameters that are changeable (a few are not); the other, [DftiGetValue](#), gets the current value of any one of these configuration parameters (all are readable). These parameters, though many, are handled one-at-a-time.
- 4. Status Checking.** The functions described in the three categories above return an integer value denoting the status of the operation. In particular, a non-zero return value always indicates a problem of some sort. Envisioned to be further enhanced in later releases of Intel MKL, FFT interface at present provides for one logical status class function, [DftiErrorClass](#), and a simple status message generation function, [DftiErrorMessage](#).

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. Two functions serve to check the status. The first function is a logical function that checks if the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

ErrorClass

Checks if the status reflects an error of a predefined class.

Syntax

Fortran:

```
Predicate = DftiErrorClass( Status, Error_Class )
```

C:

```
predicate = DftiErrorClass( status, error_class );
```

Description

The FFT interface in Intel MKL provides a set of predefined error class listed in [Table 11-2](#). These are named constants and have the type `INTEGER` in Fortran and `long` in C.

Table 11-2 Predefined Error Class

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)

Named Constants	Comments
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent
DFTI_MKL_INTERNAL_ERROR	Internal library error
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).

Note that the correct usage is to check if the status returns `.TRUE.` or `.FALSE.` through the use of `DftiErrorClass` with a specific error class. Direct comparison of a status with the predefined class is an incorrect usage. see [Example C-22](#) on a correct use of the status checking functions.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
  FUNCTION some_actual_function_8( Status, Error_Class )
    LOGICAL some_actual_function_8
    INTEGER, INTENT(IN) :: Status, Error_Class
  END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass
```

```
/* C prototype */  
long DftiErrorClass( long , long );
```

ErrorMessage

Generates an error message.

Syntax

Fortran:

```
ERROR_MESSAGE = DftiErrorMessage( Status )
```

C:

```
error_message = DftiErrorMessage( status );
```

Description

The error message function generates an error message character string. The maximum length of the string in Fortran is given by the named constant `DFTI_MAX_MESSAGE_LENGTH`. The actual error message is implementation dependent. In Fortran, the user needs to use a character string of length `DFTI_MAX_MESSAGE_LENGTH` as the target. In C, the function returns a pointer to a character string, that is, a character array with the delimiter '0'.

[Example C-22](#) shows how this function can be implemented.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_9( Status, Error_Class )
CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
INTEGER, INTENT(IN) :: Status
END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage

/* C prototype */
char *DftiErrorMessage( long );
```

Descriptor Manipulation Functions

There are four functions in this category: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

CreateDescriptor

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptor( Desc_Handle, &
Precision, &
Forward_Domain, &
Dimension, &
Length )
```

C:

```
status = DftiCreateDescriptor( &desc_handle, precision, forward_domain,
dimension, length );
```

Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. Since memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function in more traditional software packages or libraries used for computing FFT. This function does not perform any significant computation work such as twiddle factors computation. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all needed parameters.

The precision and (forward) domain are specified through named constants provided in the FFT interface for the configuration values. The choices for precision are `DFTI_SINGLE` and `DFTI_DOUBLE`; and the choices for (forward) domain are `DFTI_COMPLEX` and `DFTI_REAL`. See [Table 11-5](#) for the complete table of named constants for configuration values.

Dimension is a simple positive integer indicating the dimension of the transform. Length is either a simple positive integer for one-dimensional transform, or an integer array (pointer in C) containing the positive integers corresponding to the lengths dimensions for multi-dimensional transform.

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
!Fortran interface.
INTERFACE DftiCreateDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the keyword INTERFACE
  FUNCTION some_actual_function_1D( Desc_Handle, Prec, Dom, Dim, Length )
    INTEGER :: some_actual_function_1D

    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    INTEGER, INTENT(IN) :: Prec, Dom
    INTEGER, INTENT(IN) :: Dim, Length
  END FUNCTION some_actual_function_1D

  FUNCTION some_actual_function_HIGHD( Desc_Handle, Prec, Dom, Dim, Length )
    INTEGER :: some_actual_function_HIGHD
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    INTEGER, INTENT(IN) :: Prec, Dom
    INTEGER, INTENT(IN) :: Dim, Length(*)
  END FUNCTION some_actual_function_HIGHD
END INTERFACE DftiCreateDescriptor
```

Note that the function is overloaded as the actual argument for `Length` can be a scalar or a rank-one array.

```
/* C prototype */  
long DftiCreateDescriptor( DFTI_DESCRIPTOR_HANDLE *,  
    DFTI_CONFIG_PARAM ,  
    DFTI_CONFIG_PARAM ,  
    long , ... );
```

The variable arguments facility is used to cope with the argument for lengths that can be a scalar (`long`), or an array (`long *`).

CommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptor( Desc_Handle )
```

C:

```
status = DftiCommitDescriptor( desc_handle );
```

Description

The interface requires a function that commits a previously created descriptor be invoked before the descriptor can be used for FFT computations. Typically, this committal performs all initialization that facilitates the actual FFT computation. For a modern implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function call is immediately followed by a computation function call (see [FFT Computation](#)).

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
    FUNCTION some_actual function_1 ( Desc_Handle )
    INTEGER :: some_actual function_1
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    END FUNCTION some_actual function_1
END INTERFACE DftiCommitDescriptor

/* C prototype */
long DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

CopyDescriptor

Copies an existing descriptor.

Syntax

Fortran:

```
Status = DftiCopyDescriptor( Desc_Handle_Original, Desc_Handle_Copy )
```

C:

```
status = DftiCopyDescriptor( desc_handle_original, &desc_handle_copy );
```

Description

This function makes a copy of an existing descriptor and provides a pointer to it. The purpose is that all information of the original descriptor will be maintained even if the original is destroyed via the free descriptor function `DftiFreeDescriptor`.

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
! argument list and types of dummy arguments. The interface
! does not guarantee what the actual function names are.
! Users can only rely on the function name following the
! keyword INTERFACE
    FUNCTION some_actual_function_2( Desc_Handle_Original,
    Desc_Handle_Copy )
    INTEGER :: some_actual_function_2
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Original, Desc_Handle_Copy
    END FUNCTION some_actual_function_2
END INTERFACE DftiCopyDescriptor

/* C prototype */
long DftiCopyDescriptor( DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE * );
```

FreeDescriptor

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptor( Desc_Handle )
```

C:

```
status = DftiFreeDescriptor( &desc_handle );
```

Description

This function frees up all memory space allocated for a descriptor.

NOTE. Memory allocation/deallocation inside Intel MKL is managed by Intel MKL Memory Manager. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the Memory Manager sometimes does not return the memory space to the OS but considers the space free and can reuse it for future memory allocation. See [Example “MKL_FreeBuffers Usage with FFT Functions”](#) in the description of the service function `FreeBuffers` on how to use Intel MKL Memory Manager and actually release memory.

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
    FUNCTION some_actual_function_3( Desc_Handle )
    INTEGER :: some_actual_function_3
    TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
    END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor

/* C prototype */
long DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

FFT Computation Functions

There are two functions in this category: compute the forward transform, and compute the backward transform.

ComputeForward

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForward( Desc_Handle, X_inout )
Status = DftiComputeForward( Desc_Handle, X_in, X_out )
```

C:

```
status = DftiComputeForward( desc_handle, x_inout );
status = DftiComputeForward( desc_handle, x_in, x_out );
```

Description

As soon as a descriptor is configured and committed successfully, actual computation of the FFT can be performed. The `DftiComputeForward` function computes the forward FFT.

This is the transform using the factor $e^{-i2\pi/n}$. Because of the flexibility in configuration, input data can be represented in various ways as well as output result can be placed differently. Consequently, the number of input parameters as well as their type vary. This variation is accommodated by the generic function facility of Fortran 95. Data and result parameters are all declared as assumed-size rank-1 array `DIMENSION(0:*)`.

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
//Fortran interface.
INTERFACE DftiComputeFoward
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
// One argument single precision complex
FUNCTION some_actual_function_4_C( Desc_Handle, X )
INTEGER :: some_actual_function_4_C
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
COMPLEX, INTENT(INOUT) :: X(*)
END FUNCTION some_actual_function_4_C
// One argument double precision complex
FUNCTION some_actual_function_4_Z( Desc_Handle, X )
INTEGER :: some_actual_function_4_Z
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
COMPLEX (Kind((0D0,0D0))), INTENT(INOUT) :: X(*)
END FUNCTION some_actual_function_4_Z
// One argument single precision real
FUNCTION some_actual_function_4_R( Desc_Handle, X )
INTEGER :: some_actual_function_4_R
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
REAL, INTENT(INOUT) :: X(*)
END FUNCTION some_actual_function_4_R
// One argument double precision real
```

```

...
// Two argument single precision complex
...
...

FUNCTION some_actual_function_4_CC( Desc_Handle, X_In, Y_Out )
INTEGER :: some_actual_function_4_CC
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
COMPLEX, INTENT(IN) :: X_In(*)
COMPLEX, INTENT(OUT) :: Y_Out(*)
END FUNCTION some_actual_function_4_CC
END INTERFACE DftiComputeFoward

/* C prototype */
long DftiComputeForward( DFTI_DESCRIPTOR_HANDLE,
                        void *,
                        ... );

```

The implementations of the FFT interface expect the data be treated as data stored linearly in memory with a regular "stride" pattern (discussed more fully in [Strides](#), see also [3]). The function expects the starting address of the first element. Hence we use the assume-size declaration in Fortran.

The descriptor by itself contains sufficient information to determine exactly how many arguments and of what type should be present. The implementation could use this information to check against possible input inconsistency.

ComputeBackward

Computes the backward FFT.

Syntax

Fortran:

```
Status = DftiComputeBackward( Desc_Handle, X_inout )  
Status = DftiComputeBackward( Desc_Handle, X_in, X_out )
```

C:

```
status = DftiComputeBackward( desc_handle, x_inout );  
status = DftiComputeBackward( desc_handle, x_in, x_out );
```

Description

As soon as a descriptor is configured and committed successfully, actual computation of the FFT can be performed. The `DftiComputeBackward` function computes the backward FFT.

This is the transform using the factor $e^{i2\pi/n}$. Because of the flexibility in configuration, input data can be represented in various ways as well as output result can be placed differently. Consequently, the number of input parameters as well as their type vary. This variation is accommodated by the generic function facility of Fortran 95. Data and result parameters are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiComputeBackward
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
// One argument single precision complex
FUNCTION some_actual_function_5_C( Desc_Handle, X )
INTEGER :: some_actual_function_5_C
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
COMPLEX, INTENT(INOUT) :: X(*)
END FUNCTION some_actual_function_5_C
// One argument double precision complex
FUNCTION some_actual_function_5_Z( Desc_Handle, X )
INTEGER :: some_actual_function_5_Z
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
COMPLEX (Kind((0D0,0D0))), INTENT(INOUT) :: X(*)
END FUNCTION some_actual_function_5_Z
// One argument single precision real
FUNCTION some_actual_function_5_R( Desc_Handle, X )
INTEGER :: some_actual_function_5_R
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
REAL, INTENT(INOUT) :: X(*)
END FUNCTION some_actual_function_5_R
// One argument double precision real
```

```

...
// Two argument single precision complex
...
...

FUNCTION some_actual_function_5_CC( Desc_Handle, X_In, Y_Out )
INTEGER :: some_actual_function_5_CC
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
COMPLEX, INTENT(IN) :: X_In(*)
COMPLEX, INTENT(OUT) :: Y_Out(*)

END FUNCTION some_actual_function_5_CC
INTERFACE DftiComputeBackward END INTERFACE
DftiComputeBackward

/* C prototype */
long DftiComputeBackward( DFTI_DESCRIPTOR_HANDLE,
    void *,
    ... );

```

The implementations of the FFT interface expect the data be treated as data stored linearly in memory with a regular "stride" pattern (discussed more fully in [Strides](#), see also [3]). The function expects the starting address of the first element. Hence we use the assume-size declaration in Fortran.

The descriptor by itself contains sufficient information to determine exactly how many arguments and of what type should be present. The implementation could use this information to check against possible input inconsistency.

Descriptor Configuration Functions

There are two functions in this category: the value setting function [DftiSetValue](#) sets one particular configuration parameter to an appropriate value, and the value getting function [DftiGetValue](#) reads the value of one particular configuration parameter. While all configuration parameters are readable, a few of them cannot be set by user. Some of these contain fixed

information of a particular implementation such as version number, or dynamic information, but nevertheless are derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

SetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValue( Desc_Handle, &
Config_Param, &
Config_Val )
```

C:

```
status = DftiSetValue( desc_handle, config_param, config_val );
```

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in [Table 11-3](#), and the configuration value must have the corresponding type, which can be a named constant or a native type. See [Configuration Settings](#) for details of the meaning of the setting. Note that you can set configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS` only through the [DftiCreateDescriptor](#) function. The `DftiSetValue` function does not change these parameters.

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```

! Fortran interface
INTERFACE DftiSetValue
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_6_INTVAL( Desc_Handle, Config_Param, INTVAL )
INTEGER :: some_actual_function_6_INTVAL
Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
INTEGER, INTENT(IN) :: Config_Param
INTEGER, INTENT(IN) :: INTVAL
END FUNCTION some_actual_function_6_INTVAL

FUNCTION some_actual_function_6_SGLVAL( Desc_Handle, Config_Param, SGLVAL )
INTEGER :: some_actual_function_6_SGLVAL
Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
INTEGER, INTENT(IN) :: Config_Param
REAL, INTENT(IN) :: SGLVAL
END FUNCTION some_actual_function_6_SGLVAL

FUNCTION some_actual_function_6_DBLVAL( Desc_Handle, Config_Param, DBLVAL )
INTEGER :: some_actual_function_6_DBLVAL
Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
INTEGER, INTENT(IN) :: Config_Param
REAL (KIND(OD0)), INTENT(IN) :: DBLVAL
END FUNCTION some_actual_function_6_DBLVAL

```

```

FUNCTION some_actual_function_6_INTVEC( Desc_Handle, Config_Param, INTVEC )
INTEGER :: some_actual_function_6_INTVEC
Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
INTEGER, INTENT(IN) :: Config_Param
INTEGER, INTENT(IN) :: INTVEC(*)
END FUNCTION some_actual_function_6_INTVEC

```

```

FUNCTION some_actual_function_6_CHARS( Desc_Handle, Config_Param, CHARS )
INTEGER :: some_actual_function_6_CHARS
Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
INTEGER, INTENT(IN) :: Config_Param
CHARACTER(*), INTENT(IN) :: CHARS
END FUNCTION some_actual_function_6_CHARS
END INTERFACE DftiSetValue

```

```

/* C prototype */
long DftiSetValue( DFTI_DESCRIPTOR_HANDLE, DFTI_CONFIG_PARAM , ... );

```

GetValue

Gets the configuration value of one particular configuration parameter.

Syntax

Fortran:

```

Status = DftiGetValue( Desc_Handle, &
Config_Param, &
Config_Val )

```

C:

```
status = DftiGetValue( desc_handle, config_param, &config_val );
```

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in [Table 11-3](#) and [Table 11-4](#), and the configuration value is the corresponding appropriate type, which can be a named constant or a native type.

The function returns `DFTI_NO_ERROR` when completes successfully. See [Status Checking Functions](#) for more information on returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiGetValue
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_7_INTVAL( Desc_Handle, Config_Param, INTVAL )

```

```
FUNCTION some_actual_function_7_INTPNT( Desc_Handle, Config_Param, INTPNT )
INTEGER :: some_actual_function_7_INTPNT
Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
INTEGER, INTENT(IN) :: Config_Param
INTEGER, DIMENSION(*), POINTER :: INTPNT
END FUNCTION some_actual_function_7_INTPNT
```

```
FUNCTION some_actual_function_7_CHARS( Desc_Handle, Config_Param, CHARS )
  INTEGER :: some_actual_function_7_CHARS
  Type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
  INTEGER, INTENT(IN) :: Config_Param
  CHARACTER(*), INTENT(OUT):: CHARS
END FUNCTION some_actual_function_7_CHARS
END INTERFACE DftiGetValue
```

```
/* C prototype */
long DftiGetValue( DFTI_DESCRIPTOR_HANDLE,
                  DFTI_CONFIG_PARAM ,
                  ... );
```

Configuration Settings

Each of the configuration parameters is identified by a named constant in the MKL_DFTI module. In C, these named constants have the enumeration type DFTI_CONFIG_PARAM. The list of configuration parameters whose values can be set by user is given in Table 11-3; the list of configuration parameters that are read-only is given in Table 11-4. All parameters are readable. Most of these parameters are self-explanatory, while some others are discussed more fully in the description of the relevant functions.

Table 11-3 Settable Configuration Parameters

Named Constants	Value Type	Comments
Most common configurations, no default, must be set explicitly		
DFTI_FORWARD_DOMAIN	Named constant	Domain for the forward transform, settable by DftiCreateDescriptor only
DFTI_PRECISION	Named constant	Precision of computation, settable by DftiCreateDescriptor only

Named Constants	Value Type	Comments
DFTI_DIMENSION	Integer scalar	Dimension of the transform, settable by DftiCreateDescriptor only
DFTI_LENGTHS	Integer scalar/array	Lengths of each dimension, settable by DftiCreateDescriptor only
<i>Common configurations including multiple transform and data representation</i>		
DFTI_NUMBER_OF_TRANSFORMS	Integer scalar	For multiple number of transforms
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor for forward transform
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor for backward transform
DFTI_PLACEMENT	Named constant	Placement of the computation result
DFTI_COMPLEX_STORAGE	Named constant	Storage method, complex domain data
DFTI_REAL_STORAGE	Named constant	Storage method, real domain data
DFTI_CONJUGATE_EVEN_STORAGE	Named constant	Storage method, conjugate even domain data
DFTI_DESCRIPTOR_NAME	Character string	No longer than DFTI_MAX_NAME_LENGTH
DFTI_PACKED_FORMAT	Named constant	Packed format, real domain data
DFTI_NUMBER_OF_USER_THREADS	Integer scalar	Number of user threads employing the same descriptor for FFT computation

Configurations regarding stride of data

Named Constants	Value Type	Comments
DFTI_INPUT_DISTANCE	Integer scalar	Multiple transforms, distance of first elements
DFTI_OUTPUT_DISTANCE	Integer scalar	Multiple transforms, distance of first elements
DFTI_INPUT_STRIDES	Integer array	Stride information of input data
DFTI_OUTPUT_STRIDES	Integer array	Stride information of output data

Advanced configuration

DFTI_ORDERING	Named constant	Scrambling of data order
DFTI_TRANSPOSE	Named constant	Scrambling of dimension

Table 11-4 Read-Only Configuration Parameters

Named Constants	Value Type	Comments
DFTI_COMMIT_STATUS	Name constant	Whether descriptor has been committed
DFTI_VERSION	String	Intel MKL library version number

The configuration parameters are set by various values. Some of these values are specified by native data types such as an integer value (for example, number of simultaneous transforms requested), or a single-precision number (for example, the scale factor one would like to apply on a forward transform).

Other configuration values are discrete in nature (for example, the domain of the forward transform) and are thus provided in the DFTI module as named constants. In C, these named constants have the enumeration type `DFTI_CONFIG_VALUE`. The complete list of named constants used for this kind of configuration values is given in [Table 11-5](#).

Table 11-5 Named Constant Configuration Values

Named Constant	Comments
DFTI_SINGLE	Single precision
DFTI_DOUBLE	Double precision
DFTI_COMPLEX	Complex domain

Named Constant	Comments
DFTI_REAL	Real domain
DFTI_INPLACE	Output overwrites input
DFTI_NOT_INPLACE	Output does not overwrite input
DFTI_COMPLEX_COMPLEX	Storage method (see Storage schemes)
DFTI_REAL_REAL	Storage method (see Storage schemes)
DFTI_COMPLEX_REAL	Storage method (see Storage schemes)
DFTI_REAL_COMPLEX	Storage method (see Storage schemes)
DFTI_COMMITTED	Committal status of a descriptor
DFTI_UNCOMMITTED	Committal status of a descriptor
DFTI_ORDERED	Data ordered in both forward and backward domains
DFTI_BACKWARD_SCRAMBLED	Data scrambled in backward domain (by forward transform)
DFTI_NONE	Used to specify no transposition
DFTI_CCS_FORMAT	Packed format, real data (see Packed formats)
DFTI_PACK_FORMAT	Packed format, real data (see Packed formats)
DFTI_PERM_FORMAT	Packed format, real data (see Packed formats)
DFTI_CCE_FORMAT	Packed format, real data (see Packed formats)
DFTI_VERSION_LENGTH	Number of characters for library version length
DFTI_MAX_NAME_LENGTH	Maximum descriptor name length
DFTI_MAX_MESSAGE_LENGTH	Maximum status message length

Table 11-6 lists the possible values for those configuration parameters that are discrete in nature.

Table 11-6 Settings for Discrete Configuration Parameters

Named Constant	Possible Values
DFTI_PRECISION	DFTI_SINGLE, or DFTI_DOUBLE (no default)
DFTI_FORWARD_DOMAIN	DFTI_COMPLEX, or DFTI_REAL
DFTI_PLACEMENT	DFTI_INPLACE (default), or DFTI_NOT_INPLACE
DFTI_COMPLEX_STORAGE	DFTI_COMPLEX_COMPLEX (default)
DFTI_REAL_STORAGE	DFTI_REAL_REAL (default), or DFTI_REAL_COMPLEX
DFTI_CONJUGATE_EVEN_STORAGE	DFTI_COMPLEX_COMPLEX, or DFTI_COMPLEX_REAL (default)
DFTI_PACKED_FORMAT	DFTI_CCS_FORMAT (default), or DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT, or DFTI_CCE_FORMAT
DFTI_ORDERING	DFTI_ORDERED (default), or DFTI_BACKWARD_SCRAMBLED

Table 11-7 lists the default values of the settable configuration parameters.

Table 11-7 Default Configuration Values of Settable Parameters

Named Constants	Default Value
DFTI_NUMBER_OF_TRANSFORMS	1
DFTI_NUMBER_OF_USER_THREADS	1
DFTI_FORWARD_SCALE	1.0

Named Constants	Default Value
DFTI_BACKWARD_SCALE	1.0
DFTI_PLACEMENT	DFTI_INPLACE
DFTI_COMPLEX_STORAGE	DFTI_COMPLEX_COMPLEX
DFTI_REAL_STORAGE	DFTI_REAL_REAL
DFTI_CONJUGATE_EVEN_STORAGE	DFTI_COMPLEX_REAL
DFTI_PACKED_FORMAT	DFTI_CCS_FORMAT
DFTI_DESCRIPTOR_NAME	no name, string of zero length
DFTI_INPUT_DISTANCE	0
DFTI_OUTPUT_DISTANCE	0
DFTI_INPUT_STRIDES	Tightly packed according to dimension and FFT lengths
DFTI_OUTPUT_STRIDES	Same as above. see Strides for details
DFTI_ORDERING	DFTI_ORDERED
DFTI_TRANSPOSE	DFTI_NONE

Precision of transform

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data is meant to be presented in this precision; the computation will be carried out in this precision; and the result will be delivered in this precision. This is one of the four settable configuration parameters that do not have default values. The user must set them explicitly, most conveniently at the call to descriptor creation function [DftiCreateDescriptor](#).

Forward domain of transform

As already mentioned in the introduction to the Fourier Transform Functions chapter, the general form of the discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \pm 1, \pm 2, \dots$, where σ is an arbitrary real-valued scale factor and $\delta = \pm 1$. The forward transform is defined by $\sigma = 1$ and $\delta = -1$. In most common situations, the domain of the forward transform, that is, the set where the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs, can be either the set of complex-valued sequences, real-valued sequences, and complex-valued conjugate even sequences. The configuration parameter `DFTI_FORWARD_DOMAIN` indicates the domain for the forward transform. Note that this implicitly specifies the domain for the backward transform because of mathematical property of the FFT. See [Table 11-8](#) for details.

Table 11-8 Correspondence of Forward and Backward Domain

Forward Domain		Implied Backward Domain
Complex	(<code>DFTI_COMPLEX</code>)	Complex
Real	(<code>DFTI_REAL</code>)	Conjugate Even

On transforms in the real domain, some software packages only offer one "real-to-complex" transform. This in essence omits the conjugate even domain for the forward transform. The forward domain configuration parameter `DFTI_FORWARD_DOMAIN` is the second of four configuration parameters without default value.

Transform dimension and lengths

The dimension of the transform is a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For multi-dimensional (≥ 2) transform, the lengths of each of the dimension is supplied in an integer array (`Integer` data type in Fortran and `MKL_LONG` data type in C). `DFTI_DIMENSION` and `DFTI_LENGTHS` are the remaining two of four configuration parameters without default.

As mentioned, these four configuration parameters do not have default value. They are most conveniently set at the descriptor creation function. They can only be set in the descriptor creation function, and not by the function `DftiSetValue`.

Number of transforms

In some situations, the user may need to perform a number of FFTs of the same dimension and lengths. The most common situation would be to transform a number of one-dimensional data of the same length. This parameter has the default value of 1, and can be set to positive integer value by an `Integer` data type in Fortran and `MKL_LONG` data type in C. Data sets have no common elements. The distance parameter is obligatory if multiple number is more than one.

Scale

The forward transform and backward transform are each associated with a scale factor σ of its own with default value of 1. The user can set one or both of them via the two configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n , one can use the default scale of 1 for the forward transform while setting the scale factor for backward transform to be $1/n$, making the backward transform the inverse of the forward transform.

The scale factor configuration parameter should be set by a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

Placement of result

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. The user can change that by setting it to `DFTI_NOT_INPLACE`. Data sets have no common elements.

Packed formats

The result of the forward transform (i.e. in the frequency-domain) of real data is represented in several possible packed formats: **Pack**, **Perm**, **CCS**, or **CCE**. The data can be packed due to the symmetry property of the FFT of a real data.

The **CCE** format stores the values of the first half of the output complex conjugate-even signal resulted from the forward FFT. Note that the one-dimensional signal stored in **CCE** format is one complex element longer. For multi-dimensional real transform, $n_1 * n_2 * n_3 * \dots * n_k$ the size of complex matrix in **CCE** format is $(n_1/2+1) * n_2 * n_3 * \dots * n_k$ for Fortran and $n_1 * n_2 * \dots * (n_k/2+1)$ for C.

The **CCS** format looks like the **CCE** format. It is the same format as **CCE** for one-dimensional transform. The **CCS** format is slightly different for multi-dimensional real transform. In **CCS** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-10](#) for two-dimensional FFT.

The **Pack** format is a compact representation of a complex conjugate-symmetric sequence. The disadvantage of this format is that it is not the natural format used by the real FFT algorithms ("natural" in the sense that array is natural for complex FFTs). In **Pack** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-11](#) for two-dimensional FFT.

The **Perm** format is an arbitrary permutation of the **Pack** format for even lengths and one is the same as the **Pack** format for odd lengths. In **Perm** format, the output samples of the FFT are arranged as shown in [Table 11-9](#) for one-dimensional FFT and in [Table 11-12](#) for two-dimensional FFT.

Table 11-9 Packed Format Output Samples

For $n = s*2$

FFT Real	0	1	2	3	...	n-2	n-1	n	n+1
CCS	R_0	0	R_1	I_1	...	$R_{n/2-1}$	$I_{n/2-1}$	$R_{n/2}$	0
Pack	R_0	R_1	I_1	R_2	...	$I_{n/2-1}$	$R_{n/2}$		
Perm	R_0	$R_{n/2}$	R_1	I_1	...	$R_{n/2-1}$	$I_{n/2-1}$		

For $n = s*2 + 1$

FFT Real	0	1	2	3	...	n-4	n-3	n-2	n-1	n	n+1
CCS	R_0	0	R_1	I_1	...	I_{s-2}	R_{s-1}	I_{s-1}	R_s	I_s	
Pack	R_0	R_1	I_1	R_2	...	R_{s-1}	I_{s-1}	R_s	I_s		
Perm	R_0	R_1	I_1	R_2	...	R_{s-1}	I_{s-1}	R_s	I_s		

Note that [Table 11-9](#) uses the following notation for complex data entries:

$$R_j = \text{Re } z_j$$

$$I_j = \text{Im } z_j$$

See also [Table 11-13](#) and [Table 11-14](#).

Table 11-10 CCS Format Output Samples (Two-Dimensional Matrix $(m+2)$ -by- $(n+2)$)

For m = s*2+1

z(1,1)	z(1,k+1)	REz(1,2)	IMz(1,2)	...	REz(1,k)	IMz(1,k)

For $m = s*2+1$

REz(2,1)	REz(2,2)	REz(2,3)	REz(2,4)	...	REz(2,n-1)	REz(2,n)
IMz(2,1)	IMz(2,2)	IMz(2,3)	IMz(2,4)	...	IMz(2,n-1)	IMz(2,n)
...	...	...	...	...	...	...
REz(s,1)	REz(s,2)	REz(s,3)	REz(s,4)	...	REz(s,n-1)	REz(s,n)
IMz(s,1)	IMz(s,2)	IMz(s,3)	IMz(s,4)	...	IMz(s,n-1)	IMz(s,n)

Note that in the [Table 11-11](#) and [Table 11-12](#), for even number of columns $n = k*2$, while for odd number of columns $n = k*2+1$ and the first row is

$z(1,1)$ REz(1,2) IMz(1,2) ... REz(1,k) IMz(1,k)

If m is even, the last row in Pack format and the second row in Perm format is

$z(m/2+1,1)$ REz(m/2+1,2) IMz(m/2+1,2) ... REz(m/2+1,k) IMz(m/2+1,k)

The tables for two-dimensional FFT use Fortran-interface conventions. For C-interface specifics in storing packed data, see [Storage schemes](#) section below. See also [Table 11-15](#) and [Table 11-16](#) for examples of Fortran-interface and C-interface formats.

Storage schemes

Each value of the domain, that is, DFTI_COMPLEX, DFTI_REAL, and DFTI_CONJUGATE_EVEN (for the forward as well as the backward transform), determines a subset of the four values for storage schemes: DFTI_COMPLEX_COMPLEX, DFTI_COMPLEX_REAL, DFTI_REAL_COMPLEX, and DFTI_REAL_REAL. In [Table 11-6](#), these subsets correspond to DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, and DFTI_CONJUGATE_EVEN_STORAGE in the first-column, respectively. Specific examples are presented below to illustrate the storage schemes that are admissible for each domain. See document [3] for the rationale behind this definition of the storage schemes.

NOTE. The data is stored in the Fortran style only, that is, the real and imaginary parts are stored side by side.

Storage scheme for complex domain. This setting is recorded in the configuration parameter DFTI_COMPLEX_STORAGE. The only value that can be set is DFTI_COMPLEX_COMPLEX. Consider a one-dimensional n -length transform of the form

$$Z_k = \sum_{j=0}^{n-1} w_j e^{-i2\pi jk/n}, \quad w_j, Z_k \in \mathbb{C}.$$

Assume the stride has default value (unit stride) and `DFTI_PLACEMENT` has the default in-place setting.

DFTI_COMPLEX_COMPLEX storage scheme (by default). A typical usage will be as follows.

```
COMPLEX :: X(0:n-1)
...some other code...
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$$X(j) = w_j, \quad j = 0, 1, \dots, n-1.$$

On output,

$$X(k) = z_k, \quad k = 0, 1, \dots, n-1.$$

Storage scheme for the real and conjugate even domains. This setting for the storage schemes for these domains is recorded in the configuration parameters `DFTI_REAL_STORAGE` and `DFTI_CONJUGATE_EVEN_STORAGE`. Since a forward real domain corresponds to a conjugate even backward domain, they are considered together. The example uses [one-](#), [two-](#) and [three-dimensional](#) real to conjugate even transforms. In-place computation is assumed whenever possible (that is, when the input data type matches the output data type).

One-Dimensional Transform

Consider a one-dimensional n -length transform of the form

$$Z_k = \sum_{j=0}^{n-1} w_j e^{-i2\pi jk/n}, \quad w_j \in \mathbb{R}, Z_k \in \mathbb{C}.$$

There is a symmetry:

For even n : $z(n/2+i) = \text{conjg}(z(n/2-i))$, $1 \leq i \leq n/2-1$, and moreover $z(0)$ and $z(n/2)$ are real values.

For odd n : $z(m+i) = \text{conj}(z(m-i+1))$, $1 \leq i \leq m$, and moreover $z(0)$ is real value.
 $m = \text{floor}(n/2)$.

Table 11-13 Comparison of the Storage Effects of Complex-to-Complex and Real-to-Complex FFTs for Forward Transform

N=8

Assume that the stride has the default value (unit stride).

This complex conjugate-symmetric vector can be stored in the complex array of size $m+1$ or in the real array of size $2m+2$ or $2m$ depending on packed format.

Two-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a two-dimensional real matrix according to the mathematical equation

$$z_{i,j} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} t_{k,l} * W_m^{-i*k} * W_n^{-j*l},$$

$$0 \leq i \leq m-1, 0 \leq j \leq n-1$$

$t_{k,l} = \text{cmplx}(r_{k,l}, 0)$, where $r_{k,l}$ is a real input matrix, $0 \leq k \leq m-1, 0 \leq l \leq n-1$. The mathematical result $z_{i,j}, 0 \leq i \leq m-1, 0 \leq j \leq n-1$, is the complex matrix of size (m, n) . Each column is the complex conjugate-symmetric vector as follows:

For even m :

for $0 \leq j \leq n-1$,

$$z(m/2+i, j) = \text{conjg}(z(m/2-i, j)), 1 \leq i \leq m/2-1.$$

Moreover, $z(0, j)$ and $z(m/2, j)$ are real values for $j=0$ and $j=n/2$.

For odd m :

for $0 \leq j \leq n-1$,

$z(s+i,j) = \text{conjg}(z(s-i,j)), 1 \leq i \leq s-1,$

where $s = \text{floor}(m/2)$.

Moreover, $z(0,j)$ are real values for $j=0$ and $j=n/2$.

This mathematical result can be stored in the real two-dimensional array of size:

- $(m+2,n+2)$ (CCS format), or
- (m,n) (Pack or Perm formats), or
- $(2*(m/1+1), n)$ (CCE format, Fortran-interface),
- $((m, 2*(n/2+1)))$ (CCE format, C-interface)

or in the complex two-dimensional array of size:

- $(m/2+1, n)$ (CCE format, Fortran-interface),
- $(m, n/2+1)$ (CCE format, C-interface)

Since the multidimensional array data are arranged differently in Fortran and C (see [Strides](#)), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

The following tables give examples of output data layout in `Pack` format for a forward two-dimensional real-to-complex FFT of a 6-by-4 real matrix. Note that the same layout is used for the input data of the corresponding backward complex-to-real FFT.

Table 11-15 Fortran-interface Data Layout for a 6-by-4 Matrix

$z(1,1)$	$\text{Re } z(1,2)$	$\text{Im } z(1,2)$	$z(1,3)$
$\text{Re } z(2,1)$	$\text{Re } z(2,2)$	$\text{Re } z(2,3)$	$\text{Re } z(2,4)$
$\text{Im } z(2,1)$	$\text{Im } z(2,2)$	$\text{Im } z(2,3)$	$\text{Im } z(2,4)$
$\text{Re } z(3,1)$	$\text{Re } z(3,2)$	$\text{Re } z(3,3)$	$\text{Re } z(3,4)$
$\text{Im } z(3,1)$	$\text{Im } z(3,2)$	$\text{Im } z(3,3)$	$\text{Im } z(3,4)$
$z(4,1)$	$\text{Re } z(4,2)$	$\text{Im } z(4,2)$	$z(4,3)$

For the above example, the stride array is taken to be (0, 1, 6).

Table 11-16 C-interface Data Layout for a 6-by-4 Matrix

$z(1,1)$	$\text{Re } z(1,2)$	$\text{Im } z(1,2)$	$z(1,3)$
$\text{Re } z(2,1)$	$\text{Re } z(2,2)$	$\text{Im } z(2,2)$	$\text{Re } z(2,3)$
$\text{Im } z(2,1)$	$\text{Re } z(3,2)$	$\text{Im } z(3,2)$	$\text{Im } z(2,3)$
$\text{Re } z(3,1)$	$\text{Re } z(4,2)$	$\text{Im } z(4,2)$	$\text{Re } z(3,3)$
$\text{Im } z(3,1)$	$\text{Re } z(5,2)$	$\text{Im } z(5,2)$	$\text{Im } z(3,3)$
$z(4,1)$	$\text{Re } z(6,2)$	$\text{Im } z(6,2)$	$z(4,3)$

For the second example, the stride array is taken to be (0, 4, 1).

See also [Packed formats](#).

Three-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a three-dimensional real matrix according to the mathematical equation

$$Z_{i,j,q} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} \sum_{s=0}^{k-1} t_{p,l,s} * W_m^{-i*p} * W_n^{-j*l} * W_k^{-q*s},$$

$$0 \leq i \leq m-1, 0 \leq j \leq n-1, 0 \leq s \leq k-1$$

$t_{p,l,s} = \text{cmplx}(r_{p,l,s}, 0)$, where $r_{p,l,s}$ is a real input matrix, $0 \leq k \leq m-1$, $0 \leq l \leq n-1$, $0 \leq s \leq k-1$. The mathematical result $z_{i,j,q}$, $0 \leq i \leq m-1$, $0 \leq j \leq n-1$, $0 \leq q \leq k-1$ is the complex matrix of size (m, n, k) , which is a complex conjugate-symmetric, or conjugate even, matrix as follows:

$z_{m1,n1,k1} = \text{conjg}(z_{m-m1,n-n1,k-k1})$, where each dimension is periodic.

This mathematical result can be stored in the real three-dimensional array of size:

$(m/2+1, n, k)$ (CCE format, Fortran-interface),

$(m, n, k/2+1)$ (CCE format, C-interface).

Since the multidimensional array data are arranged differently in Fortran and C (see [Strides](#)), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

NOTE. There is one packed format for 3D REAL FFT - CCE format. In both in-place and out-of-place REAL FFT, for real data, the stride and distance parameters are in `REAL` units and for complex data, they are in `COMPLEX` units. So, elements of input and output data can be placed in different elements of input-output array of the in-place FFT.

1. `DFTI_REAL_REAL` for real domain, **`DFTI_COMPLEX_REAL`** for conjugate even domain (by default). It is used for 1D and 2D REAL FFT.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:2*m+1)
...some other code...
...assuming inplace transform...
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see [Packed formats](#)).

CCS format: $X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k), k = 0, 1, \dots, m.$

Pack format:

even n: $X(0) = \text{Re}(z_0), X(2*k-1) = \text{Re}(z_k), X(2*k) = \text{Im}(z_k), k = 1, \dots, m-1,$
and $X(n-1) = \text{Re}(z_m)$

odd n: $X(0) = \text{Re}(z_0), X(2*k-1) = \text{Re}(z_k), X(2*k) = \text{Im}(z_k), k = 1, \dots, m$

Perm format:

even n: $X(0) = \text{Re}(z_0), X(1) = \text{Re}(z_m), X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k),$
 $k = 1, \dots, m-1,$

odd n: $X(0) = \text{Re}(z_0), X(2*k-1) = \text{Re}(z_k), X(2*k) = \text{Im}(z_k), k = 1, \dots, m.$

See [Example C-16](#), [Example C-17](#), [Example C-18](#), and [Example C-19](#).

Input and output data exchange the roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
REAL :: Y(0:2*m+1)
...some other code...
...assuming out-of-place transform...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input, $X(j) = w_j$, $j = 0, 1, \dots, n-1$.

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see [Packed formats](#)).

CCS format: $Y(2*k) = \text{Re}(z_k)$, $Y(2*k+1) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$.

Pack format:

even n: $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m-1$,
and $Y(n-1) = \text{Re}(z_m)$

odd n: $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$

Perm format:

even n: $Y(0) = \text{Re}(z_0)$, $Y(1) = \text{Re}(z_m)$, $Y(2*k) = \text{Re}(z_k)$, $Y(2*k+1) = \text{Im}(z_k)$,
 $k = 1, \dots, m-1$,

odd n: $Y(0) = \text{Re}(z_0)$, $Y(2*k-1) = \text{Re}(z_k)$, $Y(2*k) = \text{Im}(z_k)$, $k = 1, \dots, m$.

Notice that if the stride of the output array is not set to the default value unit stride, the real and imaginary parts of one complex element will be placed with this stride.

For example:

CCS format: $Y(2*k*s) = \text{Re}(z_k)$, $Y((2*k+1)*s) = \text{Im}(z_k)$, $k = 0, 1, \dots, m$, s - stride.

See [Example C-16a](#) and [Example C-17a](#).

Input and output data exchange the roles in the backward transform.

2. DFTI_REAL_REAL for real domain, **DFTI_COMPLEX_COMPLEX** for conjugate even domain. It is used for 1D, 2D and 3D REAL FFT. The CCE format is set by default. You must explicitly set the storage scheme in this case, because its value is not the default one.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )

REAL :: X(0:m*2)

...some other code...

...assuming in-place transform...

Status = DftiSetValue( Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)

...

Status = DftiComputeForward( Desc_Handle, X)
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

$X(2*k) = \text{Re}(z_k), X(2*k+1) = \text{Im}(z_k), k = 0, 1, \dots, m.$

See [Example C-24](#).

Input and output data exchange the roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )

REAL :: X(0:n-1)

COMPLEX :: Y(0:m)

...some other code...

...assuming out-of-place transform...

Status = DftiSetValue( Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)

...

Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input,

$X(j) = w_j, j = 0, 1, \dots, n-1.$

On output,

$$Y(k) = z_k, \quad k = 0, 1, \dots, m.$$

See [Example C-24a](#) and [Example C-25](#)

Input and output data exchange the roles in the backward transform.

- 3. DFTI_REAL_COMPLEX** for real domain, **DFTI_COMPLEX_COMPLEX** for conjugate even domain. It is not used in the current version. See [Note in the “FFT Interface” section](#) for details. A typical usage is as follows:

```
// m = floor( n/2 )  
COMPLEX :: X(0:m)  
...some other code...  
...inplace transform...  
Status = DftiComputeForward( Desc_Handle, X )
```

On input,

$$X(j) = w_j, \quad j = 0, 1, \dots, n-1.$$

That is, the imaginary parts of $X(j)$ are zero.

On output,

$$Y(k) = z_k, \quad k = 0, 1, \dots, m,$$

where m is `floor( n/2 )`.

Number of user threads

Customer application can be parallelized by using the following techniques:

- a.** You do not create threads in your application but specify the parallel mode within the FFT module of Intel MKL. See *Intel MKL User's Guide* for more information on how to do this. See also [Example C-26 in Appendix C](#).
- b.** You create threads in the application yourself and have each thread perform all stages of FFT implementation, including descriptor initialization, FFT computation, and descriptor deallocation. In this case, each descriptor is used only within its corresponding thread. It is recommended to set single-threaded mode for Intel MKL. See [Example C-27 in Appendix C](#).
- c.** You create threads in the application yourself after initializing all FFT descriptors. This implies that threading is employed for parallel FFT computation only, and the descriptors are released upon return from the parallel region. In this case, each descriptor is used only within its corresponding thread. It is obligatory to explicitly set the single-threaded mode for Intel

MKL, otherwise, the actual number of threads may differ from one, because the `DftiCommitDescriptor` function is not in a parallel region. See [Example C-27a in Appendix C](#).

- d. You create threads in the application yourself after initializing the only FFT descriptor. This implies that threading is employed for parallel FFT computation only, and the descriptor is released upon return from the parallel region. In this case, each thread uses the same descriptor. See [Example C-28 in Appendix C](#).

In cases "a", "b", and "c", listed above, set the parameter `DFTI_NUMBER_OF_USER_THREADS` to 1 (its default value), since each particular descriptor instance is used only in a single thread.

In case "d", you must use the `DftiSetValue()` function to set the `DFTI_NUMBER_OF_USER_THREADS` to the actual number of FFT computation threads, because multiple threads will be using the same descriptor. If this setting is not done, your program will work incorrectly or fail, since the descriptor contains individual data for each thread.

WARNING.

- It is not recommended to simultaneously parallelize your program and employ the Intel MKL internal threading because this will slow down the performance. Note that in case "d" above, FFT computation is automatically initiated in a single-threading mode.
- You must not change the number of threads after the `DftiCommitDescriptor()` function completed FFT initialization.

Input and output distances

FFT interface in Intel MKL allows the computation of multiple number of transforms. Consequently, the user needs to be able to specify the data distribution of these multiple sets of data. This is accomplished by the distance between the first data element of the consecutive data sets. This parameter is obligatory if multiple number is more than one. The parameter is a value of `Integer` data type in Fortran and `MKL_LONG` data type in C. Data sets don't have any common elements. The following example illustrates the specification. Consider computing the forward FFT on three 32-length complex sequences stored in `X(0:31, 1)`, `X(0:31, 2)`, and `X(0:31, 3)`. Suppose the results are to be stored in the locations `Y(0:31, k)`, $k = 1, 2, 3$, of the array `Y(0:63, 3)`. Thus the input distance is 32, while the output distance is 64. Notice that the data and result parameters in computation functions are all declared as

assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran. Here is the code fragment:

```
Complex :: X_2D(0:31,3), Y_2D(0:63, 3)

Complex :: X(96), Y(192)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
.....
Status = DftiCreateDescriptor(Desc_Handle, DFTI_SINGLE,

    DFTI_COMPLEX, 1, 32)
Status = DftiSetValue(Desc_Handle, DFTI_NUMBER_OF_TRANSFORMS, 3)
Status = DftiSetValue(Desc_Handle, DFTI_INPUT_DISTANCE, 32)
Status = DftiSetValue(Desc_Handle, DFTI_OUTPUT_DISTANCE, 64)
Status = DftiSetValue(Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(Desc_Handle)
Status = DftiComputeForward(Desc_Handle, X, Y)
Status = DftiFreeDescriptor(Desc_Handle)
```

Strides

In addition to supporting transforms of multiple number of datasets, FFT interface supports non-unit stride distribution of data within each data set. The parameter is an array of values of `Integer` data type in Fortran and `MKL_LONG` data type in C. Consider the following situation where a 32-length FFT is to be computed on the sequence x_j , $0 \leq j < 32$. The actual location of these values are in $X(5)$, $X(7)$, ..., $X(67)$ of an array $X(1:68)$. The stride accommodated by FFT interface consists of a displacement from the first element of the data array $L0$, (4 in this case), and a constant distance of consecutive elements $L1$ (2 in this case). Thus for the Fortran array X

$$x_j = X(1 + L0 + L1 * j) = X(5 + L1 * j).$$

This stride vector (4,2) is provided by a length-2 rank-1 integer array:

```
COMPLEX :: X(68)
INTEGER :: Stride(2)
.....
Status = DftiCreateDescriptor(Desc_Handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32)
Stride = (/ 4, 2 /)
Status = DftiSetValue(Desc_Handle, DFTI_INPUT_STRIDES, Stride)
Status = DftiSetValue(Desc_Handle, DFTI_OUTPUT_STRIDES, Stride)
Status = DftiCommitDescriptor(Desc_Handle)
Status = DftiComputeForward(Desc_Handle, X)
Status = DftiFreeDescriptor(Desc_Handle)
```

In general, for a d -dimensional transform, the stride is provided by a $d+1$ -length integer vector ($L0, L1, L2, \dots, Ld$) with the meaning:

$L0$ = displacement from the first array element
 $L1$ = distance between consecutive data elements in the first dimension
 $L2$ = distance between consecutive data elements in the second dimension
 $\dots = \dots$
 Ld = distance between consecutive data elements in the d -th dimension.

A d -dimensional data sequence

$X_{j_1, j_2, \dots, j_d}, 0 \leq j_i \leq J_i, 1 \leq i \leq d$

will be stored in the rank-1 array X by the mapping

$X_{j_1, j_2, \dots, j_d} = X(\text{first index} + L0 + j_1 L1 + j_2 L2 + \dots + j_d Ld).$

For multiple transforms, the value $L0$ applies to the first data sequence, and $Lj, j = 1, 2, \dots, d$ apply to all the data sequences.

In the case of a single one-dimensional sequence, $L1$ is simply the usual stride. The default setting of strides in the general multi-dimensional situation corresponds to the case where the sequences are distributed tightly into the array:

$$L1 = 1, L2 = J_1, L3 = J_1 J_2, \dots, Ld = \prod_{i=1}^{d-1} J_i$$

Both the input data and output data have a stride associated with it. The default is set in accordance with the data to be stored contiguously in memory in a way that is natural to the language.

Note that in case of a real FFT, where different formats are available, the default value is not the one that seems most natural for certain formats. For example, with the *CCE* format, strides are set by default to $L1 = 1$, $L2 = J1$ for a real transform regardless. However, for a complex matrix, slightly over half of the matrix is actually stored, and you should set strides to $L1 = 1$, $L2 = J1/2 + 1$. In case of an *in-place* transform with the *CCE* data format, even for a real array, you should set strides explicitly: $L1 = 1$, $L2 = (J1/2 + 1) * 2$.

See [Example C-23](#) as an illustration of how to use the configuration parameters discussed above. See [Storage schemes](#) and [Packed formats](#) on how to define arrays for different formats.

Ordering

It is well known that a number of FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus permission of scrambled order is attractive if it leads to higher performance. The following options are available in Intel MKL:

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLLED`: Forward transform data ordered, backward transform data scrambled.

[Table 11-17](#) tabulates the effect on this configuration setting.

Table 11-17 Scrambled Order Transform

	<code>DftiComputeForward</code>	<code>DftiComputeBackward</code>
<code>DFTI_ORDERING</code>	Input → Output	Input → Output
<code>DFTI_ORDERED</code>	ordered → ordered	ordered → ordered

	DftiComputeForward	DftiComputeBackward
DFTI_BACKWARD_SCRAMBLED	ordered → scrambled	scrambled → ordered

Note that meaning of the latter two options are "allow scrambled order if practical." There are situations where in fact allowing out of order data gives no performance advantage, and thus an implementation may choose to ignore the suggestion. Strictly speaking, the normal order is also a scrambled order, the trivial one.

Transposition

This is an option that allows for the result of a high-dimensional transform to be presented in a transposed manner. The default setting is `DFTI_NONE` and can be set to `DFTI_ALLOW`. Similar to that of scrambled order, sometimes in higher dimension transform, performance can be gained if the result is delivered in a transposed manner. FFT interface offers an option for the output be returned in a transposed form if performance gain is possible. Since the generic stride specification is naturally suited for representation of transposition, this option allows the strides for the output to be possibly different from those originally specified by the user. Consider an example where a two-dimensional result

$$Y_{j_1, j_2}, \quad 0 \leq j_i < n_i,$$

is expected. Originally the user specified that the result be distributed in the (flat) array Y with generic strides $L_1 = 1$ and $L_2 = n_1$. With the transposition option, the computation may actually return the result into Y with stride $L_1 = n_2$ and $L_2 = 1$. These strides can be obtained from an appropriate inquiry function. Note also that in dimension 3 and above, transposition means an arbitrary permutation of the dimension.

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE. These functions are available only for the Linux* and Windows* operating systems.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic knowledge of and skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

[Table 11-18](#) lists cluster FFT functions implemented in Intel MKL:

Table 11-18 Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by [DftiComputeForwardDM](#) and [DftiComputeBackwardDM](#) functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes is created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of complex values. A cluster FFT computation function operates local part of the input data, i.e. some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions is typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` in C/C++ or `MPI_INIT` in Fortran (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling [DftiCreateDescriptorDM](#).
3. Specify a value(s) of configuration parameters by a call(s) to [DftiSetValueDM](#).
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling [DftiGetValueDM](#).
5. Initialize the descriptor for the FFT computation by calling [DftiCommitDescriptorDM](#).
6. Create arrays for local parts of input and output data and fill the local part of input data with values (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling [DftiComputeForwardDM](#) or [DftiComputeBackwardDM](#).
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling [DftiFreeDescriptorDM](#).
10. Finalize communication through MPI by calling `MPI_Finalize` in C/C++ or `MPI_FINALIZE` in Fortran (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the “[Examples for Cluster FFT Functions](#)” section in Appendix C illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order in C/C++ and in the column-major order in Fortran. For example, a two-dimensional matrix A of size (m, n) is stored in a vector B of size $m*n$ so that

- $B[i*n+j]=A[i][j]$ in C/C++ ($i=0, \dots, m-1, j=0, \dots, n-1$)
- $B(j*m+i)=A(i, j)$ in Fortran ($i=1, \dots, m, j=1, \dots, n$).

NOTE. Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with `Lengths=(m,n,l)` can be computed over an array `Ar[m][n][l]` in C/C++ or `AR(m,n,l)` in Fortran.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able to do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last one in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term “rows” will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size $(11,15,12)$, the processes may store local arrays of sizes $(6,15,12)$ and $(5,15,12)$, respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (m, n, l) , in C, each MPI process works with local data array of size (m_q, n, l) , where $\sum_{q=0}^{p-1} m_q = m$, $q=0, \dots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain

from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If `A` is a global array and `L` is the appropriate local array, then
 - `L[i][j][k]=A[i+cdft_local_start_x][j][k]`, where $i=0, \dots, m_q-1$, $j=0, \dots, n-1$, $k=0, \dots, l-1$ for C/C++
 - `L(i,j,k)=A(i,j,k+cdft_local_start_x-1)`, where $i=1, \dots, m_q$, $j=1, \dots, n$, $k=1, \dots, l$ for Fortran.

Example C-29 in Appendix C shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in Table 11-19:

Table 11-19 Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	CDFT_LOCAL_NX	CDFT_LOCAL_OUT_NX
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX

Meaning of the Parameter	Forward Transform	Backward Transform
Elements shift in output array	<code>CDFT_LOCAL_OUT_START_X</code>	<code>CDFT_LOCAL_START_X</code>

Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements are complex values, consisting of a real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table 11-20](#)), it must have the same size as the local arrays. [Example C-30](#) in Appendix C illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation effected with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory:
`examples/cdftc/examples_support.c` for C/C++ and
`examples/cdftf/examples_support.f90` for Fortran.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions in C/C++ or of the last two dimensions in Fortran must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

NOTE. The best performance of a one-dimensional FFT is reached when the transform length L is a square of an integer number: $L=N^2$.

Cluster FFT Interface

NOTE. The cluster FFT interface implemented in Intel MKL 9.0 is incompatible with previous versions. For details, refer to *Intel MKL Release Notes*.

To use the cluster FFT functions, you need to access the module `MKL_CDFT` through the "use" statement in Fortran; or access the header file `mkl_cdfti.h` through "include" in C/C++.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR_DM`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

```
INCLUDE "mpif.h"
```

(for some MPI versions, "mpif90.h" header may be used instead).

- C/C++:

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

1. **Descriptor Manipulation.** There are three functions in this category. The `DftiCreateDescriptorDM` function creates an FFT descriptor whose storage is allocated dynamically. The `DftiCommitDescriptorDM` function "commits" the descriptor to all its settings. The `DftiFreeDescriptorDM` function frees up the memory allocated for the descriptor.
2. **FFT Computation.** There are two functions in this category. The `DftiComputeForwardDM` function performs the forward FFT computation, and the `DftiComputeBackwardDM` function performs the backward FFT computation.
3. **Descriptor Configuration.** There are two functions in this category. The `DftiSetValueDM` function sets one specific configuration value to one of the many configuration parameters. The `DftiGetValueDM` function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

CreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

C/C++:

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size );
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes );
```

Input Parameters

<i>comm</i>	MPI communicator, e.g. <code>MPI_COMM_WORLD</code> .
<i>v1</i>	Precision of the transform.

<i>v2</i>	Type of the forward domain. Must be <code>DFTI_COMPLEX</code> for the current version.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

Output Parameters

<i>handle</i>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.

Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function `DftiCommitDescriptorDM` in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function `DftiSetValueDM`.

The value of the parameter *v1* is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

In C/C++, for one-dimensional transforms, length is a single integer value of the parameter *size* having type `long`; for multi-dimensional transforms, length is supplied with the parameter *sizes*, which is an array of integers having type `long`. In Fortran, length is an integer or an array of integers.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in *handle*. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
long DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
    enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,long,...);
```

CommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptorDM(handle)
```

C/C++:

```
status = DftiCommitDescriptorDM(handle);
```

Input Parameters

handle

The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Description

The cluster FFT interface requires a function that commits a previously created descriptor be invoked before the descriptor can be used for FFT computations in a particular MPI process. The [DftiCommitDescriptorDM](#) function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation](#)).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCommitDescriptorDM
    INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
    END FUNCTION
END INTERFACE
```

```
/* C/C++ prototype */
```

```
long DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

FreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptorDM(handle)
```

C/C++:

```
status = DftiFreeDescriptorDM(&handle);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .

Output Parameters

<i>handle</i>	The descriptor handle. Memory allocated for the handle is released on output.

Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiFreeDescriptorDM
  INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
    TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
  END FUNCTION
END INTERFACE

/* C/C++ prototype */

long DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

ComputeForwardDM

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForwardDM(handle, in_X, out_X)
Status = DftiComputeForwardDM(handle, in_out_X)
```

C/C++:

```
status = DftiComputeForwardDM(handle, in_X, out_X);
status = DftiComputeForwardDM(handle, in_out_X);
```

Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.

Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION. Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE. You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiComputeForwardDM
    INTEGER(4) FUNCTION DftiComputeForwardDM(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeForwardDM
    INTEGER(4) FUNCTION DftiComputeForwardDMi(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMi
    INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeForwardDMs
    INTEGER(4) FUNCTION DftiComputeForwardDMis(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMis
END INTERFACE

/* C/C++ prototype */
long DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

ComputeBackwardDM

Computes the backward FFT.

Syntax

Fortran:

```
Status = DftiComputeBackwardDM(handle, in_X, out_X)
```

```
Status = DftiComputeBackwardDM(handle, in_out_X)
```

C/C++:

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
```

```
status = DftiComputeBackwardDM(handle, in_out_X);
```

Input Parameters

handle

The descriptor handle.

in_X, in_out_X

Local part of input data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X

Local part of output data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate the array.

Description

The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION. Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE. You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

! Fortran Interface

```

        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeBackwardDM
    INTEGER(4) FUNCTION DftiComputeBackwardDMi(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(8), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeBackwardDMi
    INTEGER(4) FUNCTION DftiComputeBackwardDMs(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_x, out_X
    END FUNCTION DftiComputeBackwardDMs
    INTEGER(4) FUNCTION DftiComputeBackwardDMis(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeBackwardDMis
END INTERFACE

```

/* C/C++ prototype */

```

long DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

Descriptor Configuration Functions

There are two functions in this category: the value setting function `DftiSetValueDM` sets one particular configuration parameter to an appropriate value, the value getting function `DftiGetValueDM` reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the “FFT Functions” section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `long` in C/C++ and `INTEGER(4)` in Fortran. The exact type of the configuration parameters being floating-point scalars is `float` or `double` in C/C++ and `REAL(4)` or `REAL(8)` in Fortran. The configuration parameters whose values are named constants have the `enum` type in C/C++ and `INTEGER` in Fortran. They are defined in the `mk1_cdft.h` header file in C/C++ and `MKL_CDFT` module in Fortran.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

SetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValueDM (handle, param, value)
```

C/C++:

```
status = DftiSetValueDM (handle, param, value);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to <code>DftiCreateDescriptorDM</code> .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See Table 11-20 for the list of available parameters.
<i>value</i>	Value of the parameter.

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of the setting. See [Table 11-6](#) for possible values of the parameters that are named constants.

Table 11-20 Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.	1.0
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.	1.0
DFTI_PLACEMENT	Named constant	Placement of the computation result.	DFTI_INPLACE
DFTI_ORDERING	Named constant	Scrambling of data order.	DFTI_ORDERED
DFTI_WORKSPACE	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiSetValueDM
    INTEGER(4) FUNCTION DftiSetValueDM(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v
    END FUNCTION
    INTEGER(4) FUNCTION DftiSetValueDMd(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p
        REAL(8) :: v
    END FUNCTION
    INTEGER(4) FUNCTION DftiSetValueDMs(h, p, v)

    END FUNCTION
```

```
END INTERFACE
```

```
/* C/C++ prototype */
```

```
long DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

GetValueDM

Gets the value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValueDM(handle, param, value)
```

C/C++:

```
status = DftiGetValueDM(handle, param, &value);
```

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be retrieved from the descriptor. See Table 11-21 for the list of available parameters.

Output Parameters

<i>value</i>	Value of the parameter.

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table 11-6](#).

Table 11-21 Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms (In the current implementation of the cluster FFT interface, the value is always DFTI_COMPLEX.).
DFTI_ORDERING	Named constant	Scrambling of data order.
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes .

Parameter Name	Data Type	Description
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes .
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes .
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiGetValueDM
    INTEGER(4) FUNCTION DftiGetValueDM(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMar(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMd(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p
        REAL(8) :: v
    END FUNCTION
    INTEGER(4) FUNCTION DftiGetValueDMs(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p
        REAL(4) :: v
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
long DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix “`CDFT`” in names. [Table 11-22](#) lists error codes that the cluster FFT functions may return.

Table 11-22 Error Codes that Cluster FFT Functions Return

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error.
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation.
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters.
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters.
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
<code>DFTI_MULTITHREADED_ERROR</code>	Usually associated with a value that OMP routines return in case of errors.
<code>DFTI_BAD_DESCRIPTOR</code>	Descriptor is unusable for computation.
<code>DFTI_UNIMPLEMENTED</code>	Unimplemented legitimate settings; implementation dependent.
<code>DFTI_MKL_INTERNAL_ERROR</code>	Internal library error.
<code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).
<code>CDFT_SPREAD_ERROR</code>	Data cannot be distributed (For more information, see Distributing Data among Processes .)
<code>CDFT_MPI_ERROR</code>	MPI error. Occurs when calling MPI.

Interval Linear Solvers

Intel® MKL Interval Linear solver routines can be used for:

- solving systems of interval linear equations $Ax = b$ with an interval matrix $A = (a_{ij})$ and interval right-hand side vector $b = (b_i)$;
- checking properties of interval matrices.

For more information on key concepts of interval linear systems, see [Appendix A, “Linear Solvers Basics”](#).

Routines described below are subdivided according to the problems they solve into the following groups:

[Routines for Fast Solution of Interval Systems](#)

[Routines for Sharp Solution of Interval Systems](#)

[Routines for Inverting Interval Matrices](#)

[Routines for Checking Properties of Interval Matrices](#)

[Auxiliary and Utility Routines](#)

Table 12-1 contains the full list of Intel MKL routines for solving interval linear systems.

Table 12-1 Intel MKL Interval Linear Solver Routines

Routine Name	Description
?trtrs	Solves a triangular system of interval linear equations by backward substitution procedure.
?gegas	Solves a system of interval linear equations by interval Gauss method.
?gehss	Solves a system of interval linear equations by interval Householder method.
?gekws	Solves a system of interval linear equations by Krawczyk iteration method.
?gegss	Solves a system of interval linear equations by interval Gauss-Seidel iteration.
?gehbs	Solves a system of interval linear equations by Hansen-Bliek-Rohn procedure.
?gepps	Solves a system of interval linear equations by a parameter partitioning method.
?gepss	Solves a system of interval linear equations by a solution partitioning method.
?trtri	Computes inverse interval matrix to a triangular interval matrix.
?geszi	Computes inverse interval matrix by Schulz interval iterative procedure.
?gerbr	Tests regularity of an interval matrix by Ris-Beeck and Rex-Rohn criteria
?gesvr	Tests regularity/singularity of an interval matrix by Rump and Rex-Rohn singular value criteria.
?gemip	Performs midpoint-inverse preconditioning of an interval linear system.

Routine Naming Conventions

For the routines introduced below, the LAPACK-like naming conventions are used. Specifically, all the routine names have the structure `xyyzzz`, where the first letters `xx` indicate the data types:

<code>si</code>	real interval, single precision
<code>di</code>	real interval, double precision
<code>cr</code>	complex rectangular interval, single precision
<code>zr</code>	complex rectangular interval, double precision
<code>cc</code>	complex circular interval, single precision
<code>zc</code>	complex circular interval, double precision

The third and fourth letters `yy` indicate the matrix type:

<code>ge</code>	general
<code>tr</code>	triangular

The last three letters `zzz` indicate the computational procedure performed by the routine:

<code>trs</code>	backward substitution solver for triangular interval linear systems
<code>gas</code>	interval Gauss solver for interval linear systems
<code>hss</code>	interval Householder solver for interval linear systems
<code>kws</code>	iterative Krawczyk solver for interval linear systems
<code>gss</code>	interval Gauss-Seidel iteration solver for interval linear systems
<code>hbs</code>	Hansen-Bliek-Rohn solver for interval linear systems
<code>pps</code>	parameter partitioning method-based solver for interval linear systems
<code>pss</code>	solution partitioning method-based solver for interval linear systems
<code>tri</code>	inverting triangular interval matrix based on backward substitution
<code>szi</code>	inverting general interval matrix by Schulz iterative method
<code>rbr</code>	testing regularity/singularity of interval matrix by Ris-Beeck criterion
<code>svr</code>	testing regularity/singularity of interval matrix by Rump and Rex-Rohn singular value criteria
<code>mip</code>	midpoint-inverse preconditioning of interval linear system

The question mark in the routine group name corresponds to different character codes indicating the data type (`si`, `di`, `cr`, `zr`, `cc`, or `zc`). For example, `?trtri` denotes the group name for either of the routines `sitrtri`, `ditrtri`, `crttrtri`, `zrttrtri`, `cctrtri`, or `zcctrtri`.

Routines for Fast Solution of Interval Systems

?trtrs

Solves a triangular system of interval linear equations by backward substitution procedure.

Syntax

```
call sitrtrs(uplo, trans, diag, n, nrhs, a, lda, b, ldb, info)
call ditrtrs(uplo, trans, diag, n, nrhs, a, lda, b, ldb, info)
call crtrtrs(uplo, trans, diag, n, nrhs, a, lda, b, ldb, info)
call zrtrtrs(uplo, trans, diag, n, nrhs, a, lda, b, ldb, info)
call cctrtrs(uplo, trans, diag, n, nrhs, a, lda, b, ldb, info)
call zctrtrs(uplo, trans, diag, n, nrhs, a, lda, b, ldb, info)
```

Description

The routine ?trtrs solves for X the following systems of interval linear equations with a triangular matrix A and multiple right-hand sides stored in B :

$$A^*X = B, \text{ if } trans = 'N'$$

$$A^T * X = B, \text{ if } trans = 'T'$$

$$A^H * X = B, \text{ if } trans = 'C' \text{ (for complex matrices only).}$$

The routine implements backward substitution algorithm and produces optimal enclosures of the solution sets to interval linear systems, which is due to the simple structure of the matrix A .

Input Parameters

<i>uplo</i>	CHARACTER(1). Must be one of 'U', 'L', 'u', or 'l'. Indicates whether A is upper or lower triangular. If <i>uplo</i> = 'U' or 'u', then A is upper triangular. If <i>uplo</i> = 'L' or 'l', then A is lower triangular.
<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. If <i>trans</i> = 'N' or 'n', then $A^*X = B$ is solved for X .

	If $trans = 'T'$ or $'t'$, then $A^T * X = B$ is solved for X. If $trans = 'C'$ or $'c'$, then $A^H * X = B$ is solved for X.
<i>diag</i>	CHARACTER(1). Must be one of 'N', 'U', 'n', or 'u'. If $diag = 'N'$ or $'n'$, then A is not a unit triangular matrix. If $diag = 'U'$ or $'u'$, then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a.
<i>n</i>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a, b</i>	S_INTERVAL for sitrtrs. D_INTERVAL for ditrtrs. CR_INTERVAL for crrtrs. ZR_INTERVAL for zrrtrs. CC_INTERVAL for cctrtrs. ZC_INTERVAL for zcctrtrs. Arrays: $a(la, *)$, $b(lb, *)$. The array a contains the matrix A. The array b contains the matrix B, whose columns are the right-hand sides for the systems of equations. The second dimension of a must be at least $\max(1, n)$ and the second dimension of b must be at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The first dimension of a , $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of b , $ldb \geq \max(1, nrhs)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info \geq 1$, the execution is not successful. If $info = -i$, the i-th parameter has an illegal value.

?gegas

Solves a system of interval linear equations by interval Gauss method.

Syntax

```
call sigegas(trans, n, nrhs, a, lda, b, ldb, info)
call digegas(trans, n, nrhs, a, lda, b, ldb, info)
call crgegas(trans, n, nrhs, a, lda, b, ldb, info)
call zrgegas(trans, n, nrhs, a, lda, b, ldb, info)
call ccgegas(trans, n, nrhs, a, lda, b, ldb, info)
call zcgegas(trans, n, nrhs, a, lda, b, ldb, info)
```

Description

The routine ?gegas uses the interval Gauss method to compute an enclosure of the solution set to the following interval linear system of equations:

$A^*X = B$, if $trans = 'N'$

$A^T * X = B$, if $trans = 'T'$

$A^H * X = B$, if $trans = 'C'$ (for complex matrices only).

Input Parameters

<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If $trans = 'N'$ or 'n', then $A^*X = B$ is solved for X . If $trans = 'T'$ or 't', then $A^T * X = B$ is solved for X . If $trans = 'C'$ or 'c', then $A^H * X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a, b</i>	REAL for sigegas. DOUBLE PRECISION for digegas. Arrays: a ($lda, *$), b ($ldb, *$). The array a contains the matrix A .

The array b contains the matrix B , whose columns are the right-hand sides for the systems of equations.

The second dimension of a must be at least $\max(1, n)$ and the second dimension of b must be at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of a , $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of b , $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix x .

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info \geq 0$, the execution is not successful.

If $info = -i$, the i -th parameter has an illegal value.

Example 12-1 Fortran 90 Code for Interval Gauss Method

The following piece of Fortran code presents an example of using the routine `digegas` to compute, by an interval Gauss method, an enclosure of the solution set to the interval linear system of equations:

$$\begin{pmatrix} [2, 3] & [0, 1] \\ [1, 2] & [2, 3] \end{pmatrix} x = \begin{pmatrix} [0, 120] \\ [60, 240] \end{pmatrix}$$

```

-----
. . . . .
USE INTERVAL_ARITHMETIC
. . . . .
TYPE(D_INTERVAL)          :: A(2,2), B(2)
INTEGER                   :: N, INFO
CHARACTER(1)              :: TRANS = 'n'
. . . . .
N = 2
A(1,1) = DINTERVAL(2.,3.);   A(1,2) = DINTERVAL(0.,1.)
A(2,1) = DINTERVAL(1.,2.);   A(2,2) = DINTERVAL(2.,3.)
B(1,1) = DINTERVAL(0.,120.); B(2,1) = DINTERVAL(60.,240.)
. . . . .
CALL DIGEGAS( TRANS, N, 1, A, 2, B, 2, INFO )
-----

```

Note that assigning double-precision intervals to the entries of the matrix *A* and right-hand side vector *B* is carried out by `DINTERVAL` function supplied by `INTERVAL_ARITHMETIC` module.

?gehss

Solves a system of interval linear equations by interval Householder method.

Syntax

```

call sigehss(trans, n, nrhs, a, lda, b, ldb, info)
call digehss(trans, n, nrhs, a, lda, b, ldb, info)

```

Description

The routine `?gehss` uses the interval Householder method to compute an enclosure of the solution set to the following interval linear system of equations:

$$A * X = B, \text{ if } trans = 'N',$$

$A^T * X = B$, if *trans* = 'T' or 'C'.

Input Parameters

<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If <i>trans</i> = 'N' or 'n', then $A * X = B$ is solved for X . If <i>trans</i> = 'T' or 'C' or 't' or 'c', then $A^T * X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a</i> , <i>b</i>	REAL for <i>sgehss</i> . DOUBLE PRECISION for <i>dgehss</i> . Arrays: <i>a</i> (<i>lda</i> , *), <i>b</i> (<i>ldb</i> , *). The array <i>a</i> contains the matrix A . The array <i>b</i> contains the matrix B , whose columns are the right-hand sides for the systems of equations. The second dimension of <i>a</i> must be at least $\max(1, n)$ and the second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> , $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> , $ldb \geq \max(1, nrhs)$.

Output Parameters

<i>b</i>	Overwritten by an enclosure of the solution matrix X .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> ≥ 1 , the execution is not successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter has an illegal value.

?gekws

Solves a system of interval linear equations by Krawczyk iteration method.

Syntax

```
call sigekws(trans, n, nrhs, a, lda, b, ldb, epsilon, info)
call digekws(trans, n, nrhs, a, lda, b, ldb, epsilon, info)
call crgekws(trans, n, nrhs, a, lda, b, ldb, epsilon, info)
call zrgekws(trans, n, nrhs, a, lda, b, ldb, epsilon, info)
call ccgekws(trans, n, nrhs, a, lda, b, ldb, epsilon, info)
call zcgekws(trans, n, nrhs, a, lda, b, ldb, epsilon, info)
```

Description

The routine ?gekws uses the Krawczyk interval iteration to compute an enclosure of the solution set to the following interval linear system of equations:

$A^*X = B$, if $trans = 'N'$

$A^T * X = B$, if $trans = 'T'$

$A^H * X = B$, if $trans = 'C'$ (for complex matrices only).

Input Parameters

<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If $trans = 'N'$ or 'n', then $A^*X = B$ is solved for X . If $trans = 'T'$ or 't', then $A^T * X = B$ is solved for X . If $trans = 'C'$ or 'c', then $A^H * X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a, b</i>	S_INTERVAL for sigekws. D_INTERVAL for digekws. CR_INTERVAL for crgekws. ZR_INTERVAL for zrgekws.

CC_INTERVAL for ccgekws.

ZC_INTERVAL for zcgekws.

Arrays: a ($lda, *$), b ($ldb, *$).

The array a contains the matrix A .

The array b contains the matrix B , whose columns are the right-hand sides for the systems of equations.

lda INTEGER. The first dimension of a , $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of b , $ldb \geq \max(1, n)$.

$epsilon$ REAL for sigekws, crgekws, and ccgekws.
DOUBLE PRECISION for digekws, zrgekws, and zcgekws.
The prescribed accuracy of the estimate.

Output Parameters

b Overwritten by an enclosure of the solution matrix x .

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info \geq 0$, the execution is not successful.
If $info = -i$, the i -th parameter has an illegal value.

Application Notes

Krawczyk interval iteration already incorporates midpoint inverse preconditioning, so that additional application of ?gemip routines is not necessary and does not improve the overall efficiency.

?gegss

Solves a system of interval linear equations by interval Gauss-Seidel iteration.

Syntax

```
call sigegss(trans, n, nrhs, a, lda, b, ldb, encl, epsilon, nits, info)
call digegss(trans, n, nrhs, a, lda, b, ldb, encl, epsilon, nits, info)
call crgegss(trans, n, nrhs, a, lda, b, ldb, encl, epsilon, nits, info)
call zrgegss(trans, n, nrhs, a, lda, b, ldb, encl, epsilon, nits, info)
call ccgegss(trans, n, nrhs, a, lda, b, ldb, encl, epsilon, nits, info)
call zcgegss(trans, n, nrhs, a, lda, b, ldb, encl, epsilon, nits, info)
```

Description

The routine ?gegss uses the interval Gauss-Seidel iteration to compute an enclosure of a portion of the solution set to the following interval linear system of equations:

$A^*X = B$, if $trans = 'N'$

$A^T * X = B$, if $trans = 'T'$

$A^H * X = B$, if $trans = 'C'$ (for complex matrices only).

See in Appendix C of this manual for example code on using this routine.

Input Parameters

<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If $trans = 'N'$ or 'n', then $A^*X = B$ is solved for X . If $trans = 'T'$ or 't', then $A^T * X = B$ is solved for X . If $trans = 'C'$ or 'c', then $A^H * X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a, b</i>	S_INTERVAL for sigegss. D_INTERVAL for digegss. CR_INTERVAL for crgegss.

	ZR_INTERVAL for zrgegss. CC_INTERVAL for ccgegss. ZC_INTERVAL for zcgegss. Arrays: <i>a</i> (<i>lda</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>a</i> contains the matrix <i>A</i> . The array <i>b</i> contains the matrix <i>B</i> , whose columns are the right-hand sides for the systems of equations.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> , $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> , $ldb \geq \max(1, n)$.
<i>encl</i>	S_INTERVAL for sigegss. D_INTERVAL for digegss. CR_INTERVAL for crgegss. ZR_INTERVAL for zrgegss. CC_INTERVAL for ccgegss. ZC_INTERVAL for zcgegss. Array: <i>encl</i> (<i>ldb</i> ,*). The array <i>encl</i> defines the interval box bounding the portion of the solution set that the routine estimates.
<i>epsilon</i>	REAL for sigegss, crgegss, and ccgegss. DOUBLE PRECISION for digegss, zrgegss, and zcgegss. The prescribed accuracy of the estimate.
<i>nits</i>	INTEGER. The number of Gauss-Seidel iterations, $nits \geq 0$.

Output Parameters

<i>b</i>	Overwritten by an enclosure of the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i> ≥ 0, then the diagonal element <i>a</i> (<i>i</i> , <i>i</i>) of the matrix contains zero. The execution of the routine did not fail, but it is recommended to interchange the rows and/or columns of the matrix so as to exclude zero-containing elements from its main diagonal. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter has an illegal value.

Application Notes

Interval Gauss-Seidel iteration is a *local solver* of interval linear systems, which means that it is mainly intended for computing enclosures of portions of the solution set bounded by a given interval box in the space R^n .

If the goal is to compute, by `?gegs`, an enclosure of the entire solution set to an interval linear system of equations, then its initial (crude) enclosure should be provided through `encl` argument.

?gehbs

Solves a system of interval linear equations by Hansen-Bliek-Rohn procedure.

Syntax

```
call sigehts(trans, n, a, lda, b, ldb, info)
call digehts(trans, n, a, lda, b, ldb, info)
```

Description

The routine `?gehts` uses the Hansen-Bliek-Rohn procedure to compute an enclosure of the solution set to the following interval linear system of equations:

$A^*X = B$, if `trans = 'N'`,

$A^T * X = B$, if `trans = 'T' or 'C'`.

See in Appendix C of this manual for example code on using this routine.

Input Parameters

<code>trans</code>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If <code>trans = 'N'</code> or 'n', then $A^*X = B$ is solved for X . If <code>trans = 'T'</code> or 'C' or 't' or 'c', then $A^T * X = B$ is solved for X .
<code>n</code>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<code>a, b</code>	REAL for <code>sigehts</code> . DOUBLE PRECISION for <code>digehts</code> . Arrays: <code>a (lda,*)</code> , <code>b (ldb,*)</code> . The array <code>a</code> contains the matrix A .

The array *b* contains the matrix *B*, whose columns are the right-hand sides for the systems of equations.

lda INTEGER. The first dimension of *a*, $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*, $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix *x*.

info INTEGER.

If *info* = 0, the execution is successful.

If *info* ≥ 0, the execution is not successful.

If *info* = -*i*, the *i*-th parameter has an illegal value.

Application Notes

If the middle matrix of *A* is not close to a diagonal matrix, then the midpoint inverse preconditioning by ?gemip routine may be necessary to correct the interval linear system and yield better results.

Routines for Sharp Solution of Interval Systems

?gepps

Solves a system of interval linear equations by a parameter partitioning method.

Syntax

call sigepps(*trans*, *n*, *a*, *lda*, *b*, *ldb*, *cmpt*, *mode*, *estm*, *epsilon*, *nits*, *info*)

call digepps(*trans*, *n*, *a*, *lda*, *b*, *ldb*, *cmpt*, *mode*, *estm*, *epsilon*, *nits*, *info*)

Description

The routine ?gepps uses the parameter partitioning (PPS) method to compute some (or all) of the sharp outer component-wise estimates of the solution set to the following interval linear system of equations:

$A * X = B$, if *trans* = 'N',

$A^T * X = B$, if $trans = 'T' \text{ or } 'C'$.

Input Parameters

<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If $trans = 'N' \text{ or } 'n'$, then $A * X = B$ is solved for X. If $trans = 'T' \text{ or } 'C' \text{ or } 't' \text{ or } 'c'$, then $A^T * X = B$ is solved for X.
<i>n</i>	INTEGER. The order of A, the number of rows in B ($n \geq 0$).
<i>a, b</i>	REAL for sigepps. DOUBLE PRECISION for digepps. Arrays: $a(lda, *)$, $b(l db)$. The array a contains the matrix A. The array b contains the vector B of the right-hand sides for the system of equations.
<i>lda</i>	INTEGER. The first dimension of a, $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of b, $ldb \geq \max(1, n)$.
<i>cmpt</i>	INTEGER. The number of the component of the solution set to be estimated.
<i>mode</i>	CHARACTER(1). Must be either 'L' or 'U' (or the corresponding lowercase letters). Indicates how to estimate the solution set along the coordinate direction specified by the parameter <i>cmpt</i>: if $mode = 'L' \text{ or } 'l'$, then the routine computes the lower estimate of the solution set over the <i>cmpt</i>-th coordinate; if $mode = 'U' \text{ or } 'u'$, then the routine computes the upper estimate of the solution set over the <i>cmpt</i>-th coordinate.
<i>epsilon</i>	REAL for sigepps. DOUBLE PRECISION for digepps. The prescribed accuracy of the estimate.
<i>nits</i>	INTEGER. The number of iterations of the PPS algorithm, $nits \geq 0$.

Output Parameters

<i>estm</i>	REAL for sigepps.

	DOUBLE PRECISION for <code>digepps</code> .
	Estimate of the solution set along the coordinate axis with the number <code>cmpt</code> . if <code>mode = 'L'</code> , then <code>estm</code> represents the lower estimate of the solution set. if <code>mode = 'U'</code> , then <code>estm</code> is equal to the upper estimate of the solution set.
<code>epsilon</code>	The actual precision of the estimate.
<code>nits</code>	The number of iterations that the algorithm actually executed.
<code>info</code>	INTEGER. If <code>info = 0</code> , the execution is successful. If <code>info = i ≥ 0</code> , the execution is not successful. If <code>info = -i</code> , the <i>i</i> -th parameter has an illegal value.

Application Notes

Routines `?gepps` and `?gepss` implement two mutually dual algorithms for computing optimal estimates of the solution sets to interval linear systems, which use adaptive partitioning of either parameter set or solution set of the system. The choice of either of these methods should be based on the specific features of the problem under solution such as the number of essentially interval parameters, the shape of the solution set, and so on.

For example, if the interval system has few interval parameters, then PPS-method is preferable, while PSS-method works better for systems that have simple shape of the solution set.

Computing optimal (or sharp) enclosures of the solution sets to interval linear systems, as well as enclosures that are guaranteed to be sharp within a prescribed accuracy, is known to be an NP-hard problem.

Therefore, a good choice of the parameters `epsilon` and `nits` becomes crucial for effective work of `?gepps` and `?gepss` routines and for producing desired results.

With this in mind, the recommendation is to organize the whole solution process with `?gepps` or `?gepss` interactively as a sequence of routine calls, starting from a moderate `nits` and a rough `epsilon` and then increasing `nits` and reducing `epsilon` until `?gepps` or `?gepss` still complete their execution.

?gepss

Solves a system of interval linear equations by a solution partitioning method.

Syntax

```
call sigepss( trans, n, a, lda, b, ldb, cmpt, mode, estm, epsilon, nits, info)
call digepss( trans, n, a, lda, b, ldb, cmpt, mode, estm, epsilon, nits, info)
```

Description

The routine ?gepss uses the (PSS) method to compute a sharp outer component-wise estimate, along a prescribed coordinate axis, of the solution set to the following interval linear system of equations:

$A * X = B$, if $trans = 'N'$,

$A^T * X = B$, if $trans = 'T'$ or $'C'$.

Input Parameters

<i>trans</i>	CHARACTER(1). Must be one of 'N', 'T', 'C', 'n', 't', or 'c'. Indicates the form of the equations system: If $trans = 'N'$ or $'n'$, then $A * X = B$ is solved for X . If $trans = 'T'$ or $'C'$ or $'t'$ or $'c'$, then $A^T * X = B$ is solved for X .
<i>n</i>	INTEGER. The order of A , the number of rows in B ($n \geq 0$).
<i>a, b</i>	REAL for sigepss. DOUBLE PRECISION for digepss. Arrays: $a(lda, *)$, $b(ldb)$. The array a contains the matrix A . The array b contains the vector B of the right-hand sides for the system of equations to be solved.
<i>lda</i>	INTEGER. The first dimension of a , $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of b , $ldb \geq \max(1, n)$.
<i>cmpt</i>	INTEGER. The number of the component of the solution set to be estimated.
<i>mode</i>	CHARACTER(1). Must be either 'L' or 'U' (or the corresponding lowercase letters).

Indicates how to estimate the solution set along the coordinate direction specified by the parameter *cmpt*:
 if *mode* = 'L' or 'l', then the routine computes the lower estimate of the solution set over the *cmpt*-th coordinate;
 if *mode* = 'U' or 'u', then the routine computes the upper estimate of the solution set over the *cmpt*-th coordinate.

epsilon REAL for *sigepps*.
 DOUBLE PRECISION for *digepps*.
 The prescribed accuracy of the estimate for the solution set.

nits INTEGER. The number of iterations of the PSS algorithm, *nits* ≥ 0.

Output Parameters

estm REAL for *sigepps*.
 DOUBLE PRECISION for *digepps*.
 Estimate of the solution set along the coordinate axis with the number *cmpt*. if *mode* = 'L', then *estm* represents the lower estimate of the solution set. if *mode* = 'U', then *estm* is equal to the upper estimate of the solution set.

epsilon The actual precision of the estimate *estm*.

nits INTEGER. The number of iterations that the algorithm actually executed.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = *i* ≥ 0, the execution is not successful.
 If *info* = -*i*, the *i*-th parameter has an illegal value and the routine outputs the corresponding message.

Application Notes

Routines *?gepps* and *?gepps* implement two mutually dual algorithms for computing optimal estimates of the solution sets to interval linear systems, which use adaptive partitioning of either parameter set or solution set of the system. The choice of either of these methods should be based on the specific features of the problem under solution such as the number of essentially interval parameters, the shape of the solution set, and so on.

For example, if the interval system has few interval parameters, then PPS-method is preferable, while PSS-method works better for systems that have simple shape of the solution set.

Computing optimal (or sharp) enclosures of the solution sets to interval linear systems, as well as enclosures that are guaranteed to be sharp within a prescribed accuracy, is known to be an NP-hard problem.

Therefore, a good choice of the parameters *epsilon* and *nits* becomes crucial for effective work of ?gepps and ?gepss routines and for producing desired results.

With this in mind, the recommendation is to organize the whole solution process with ?gepps or ?gepss interactively as a sequence of routine calls, starting from a moderate *nits* and a rough *epsilon* and then increasing *nits* and reducing *epsilon* until ?gepps or ?gepss still complete their execution.

Example 12-2 Fortran 90 Code for Parameter Partitioning (PPS) Method

Consider a sample problem that requires computing a sharp lower estimate (to within the accuracy of, say, $1.E-4$), along the first coordinate direction, of the solution set to the interval linear system

$$\begin{pmatrix} 3.5 & [0, 2] & [0, 2] \\ [0, 2] & 3.5 & [0, 2] \\ [0, 2] & [0, 2] & 3.5 \end{pmatrix} x = \begin{pmatrix} [-1, 1] \\ [-1, 1] \\ [-1, 1] \end{pmatrix}$$

The problem can be solved by the following Fortran code that implements parameter partitioning method (PPS-method) and uses `sigepps` routine:

```

-----
. . . . .
USE INTERVAL_ARITHMETIC
. . . . .
INTEGER, PARAMETER          :: LDA = 3, LDB = 3
INTEGER                      :: NITS, CMPT, INFO, I, J
CHARACTER(1)                 :: MODE = 'L'
REAL(4)                      :: EPS, ESTM
TYPE(S_INTERVAL)             :: A(3,3), B(3)
. . . . .
DO I = 1, 3
    DO J = 1, 3
        IF( I/=J ) THEN
            A(I,J) = SINTERVAL(0.,2.)
        ELSE
            A(I,J) = SINTERVAL(3.5)
        END IF
        B(I) = SINTERVAL(-1.,1.)
    END DO
END DO

CMPT = 1
NITS = 100
EPS= 1.E-4
. . . . .
CALL SIGEPPS( 'n', 3, A, LDA, B, LDB, CMPT, MODE, ESTM, EPS, NITS, INFO )
-----

```

To guarantee the completion of the algorithm, the value of the parameter `NITS` is set equal to 100 (iterations), which is enough for the above specific example. Note that assigning single-precision intervals to the entries of the matrix `A` and right-hand side vector `B` is carried out by `SINTERVAL` function supplied by `INTERVAL_ARITHMETIC` module.

Routines for Inverting Interval Matrices

?trtri

Computes inverse interval matrix to a triangular interval matrix.

Syntax

```
call sitrtri(uplo, diag, n, a, lda, info)
call ditrtri(uplo, diag, n, a, lda, info)
call crtrtri(uplo, diag, n, a, lda, info)
call ztrtrtri(uplo, diag, n, a, lda, info)
call cctrtri(uplo, diag, n, a, lda, info)
call zctrtri(uplo, diag, n, a, lda, info)
```

Description

The routine `?trtri` computes an interval enclosure of the inverse $\text{inv}(A)$ of an interval triangular matrix `A`.

This routine implements a backward substitution algorithm and produces optimal enclosures of the inverse interval matrix, which is due to the simple structure of the matrix to be inverted.

Input Parameters

<code>uplo</code>	CHARACTER(1). Must be one of 'U', 'L', 'u', or 'l'. Indicates whether <code>A</code> is upper or lower triangular. If <code>uplo</code> = 'U' or 'u', then <code>A</code> is upper triangular. If <code>uplo</code> = 'L' or 'l', then <code>A</code> is lower triangular.
<code>diag</code>	CHARACTER(1). Must be one of 'N', 'U', 'n', or 'u'. If <code>diag</code> = 'N' or 'n', then <code>A</code> is not a unit triangular matrix.

If *diag* = 'U' or 'u', then *A* is unit triangular: diagonal elements of *A* are assumed to be 1 and not referenced in the array *a*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

a S_INTERVAL for sitrtri.
D_INTERVAL for ditrtri.
CR_INTERVAL for cctrtri.
ZR_INTERVAL for ztrtri.
CC_INTERVAL for cctrtri.
ZC_INTERVAL for zctrtri.
Array: DIMENSION (*lda*, *).
Contains the matrix *A*.
The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*, $lda \geq \max(1, n)$.

Output Parameters

a Overwritten by an interval *n*-by-*n* matrix that encloses the inverse matrix $\text{inv}(A)$.

info INTEGER.
If *info* = 0, the execution was successful.
If *info* = -*i*, the *i*-th parameter has an illegal value.
If *info* = *i*, the *i*-th diagonal element of *A* contains zero, *A* is singular, and its inversion could not be completed.

?geszi

Computes inverse interval matrix by Schulz iterative method.

Syntax

```
call sigeszi(n, a, lda, info)
call digeszi(n, a, lda, info)
```

Description

For a general interval square matrix *A*, the routine ?geszi computes an enclosure of the inverse interval matrix $\text{inv}(A)$ by the Schulz iterative method.

See in Appendix C of this manual for example code on using this routine.

Input Parameters

n INTEGER. The order of the matrix *A* ($n \geq 0$).

a REAL for *sigeszi*.
DOUBLE PRECISION for *digeszi*.
Array: DIMENSION (*lda*,*).
Contains the matrix *A*.
The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*, $lda \geq \max(1, n)$.

Output Parameters

a Overwritten by an enclosure of the inverse interval matrix $\text{inv}(A)$.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = *i* ≥ 0 , the execution is not successful.
If *info* = -*i*, the *i*-th parameter has an illegal value.

Application Notes

Schulz iteration implemented in *?geszi* routine converges only provided that the interval matrix *A* is not "too wide". Otherwise, when Schulz iteration diverges, the result is set equal to the interval matrix with the elements $[-\text{infty}, +\text{infty}]$, where *infty* is computer infinity of the corresponding kind.

Routines for Checking Properties of Interval Matrices

?gerbr

Tests regularity of an interval matrix by Ris-Beeck and Rex-Rohn criteria.

Syntax

```
call sigerbr( n, a, lda, sr, reg, info )
call digerbr( n, a, lda, sr, reg, info )
```

Description

The routine `?gerbr` checks whether a general interval square matrix A is regular or singular by using a combination of Ris-Beeck spectral criterion and Rex-Rohn test.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a</i>	REAL for <code>sigerbr</code> . DOUBLE PRECISION for <code>digerbr</code> . Array: DIMENSION (<i>lda</i> ,*). Contains the matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> , $lda \geq \max(1, n)$.

Output Parameters

<i>sr</i>	REAL for <code>sigerbr</code> . DOUBLE PRECISION for <code>digerbr</code> . An upper estimate of the spectral radius of the matrix $(\text{inv}(\text{mid } A) \cdot \text{rad } A)$. This is an additional information about the matrix A , which is crucial for the so-called strong regularity of A .
<i>reg</i>	INTEGER. Displays the results of the singularity test. If $reg \geq 0$, then A is regular. If $reg < 0$, then A is singular. If $reg = 0$, then the result is undetermined, that is, the test was not sufficiently sensitive to detect whether the matrix A is regular or singular.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = i \geq 0$, the execution is not successful. If $info = -i$, the i -th parameter has an illegal value.

Application Notes

The test implemented in the routine `?gerbr` is rather crude, and in critical cases further investigation of the matrix A is recommended. However, the routine may help to determine (by comparing the value of sr with 1) whether an interval matrix is strongly regular or not.

?gesvr

*Tests regularity/singularity of an interval matrix
by Rump and Rex-Rohn singular value criteria.*

Syntax

```
call sigesvr(n, a, lda, msr, rsr, reg, info)
call digesvr(n, a, lda, msr, rsr, reg, info)
```

Description

The routine `?gesvr` checks whether a general interval square matrix A is regular or singular by using Rump and Rex-Rohn singular value criteria.

Input Parameters

n INTEGER. The order of the matrix A ($n \geq 0$).

a REAL for `sigesvr`.
DOUBLE PRECISION for `digesvr`.
Array: DIMENSION (*lda*, *).
Contains the matrix A .
The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*, $lda \geq \max(1, n)$.

Output Parameters

msr, rsr S_INTERVAL for `sigesvr`.
D_INTERVAL for `digesvr`.
Additional information about the matrix A .
The intervals represent the ranges of the singular spectra of the midpoint matrix and radius matrix, respectively.

reg INTEGER. Displays results of the singularity test.

If $reg \geq 0$, then A is regular.

If $reg < 0$, then A is singular.

If $reg = 0$, then the result is undetermined, that is, the test was not sufficiently sensitive to detect whether the matrix A is regular or singular.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = i \geq 0$, the execution is not successful.

If $info = -i$, the i -th parameter has an illegal value.

Application Notes

The routine `?gesvr` implements a test that is only a sufficient condition for a matrix to be either regular or singular. This means that in some boundary cases the test may prove not sensitive enough to determine whether a given matrix is regular or singular, and the routine returns $reg = 0$ on output.

Example 12-3 Fortran 90 Code for Testing Regularity of Interval Matrix by Singular Value Criteria

To test regularity of the interval matrix

$$\begin{pmatrix} [2, 4] & [-1, 2] \\ [-2, 1] & [2, 4] \end{pmatrix}$$

by singular value criteria, the following piece of Fortran 90 code may be helpful:

```

-----
. . . . .
USE INTERVAL_ARITHMETIC

. . . . .
INTEGER, PARAMETER      :: LDA = 2, N = 2
TYPE(D_INTERVAL)        :: A(LDA,N), MSR, RSR
INTEGER                  :: REG, INFO

. . . . .
A(1,1) = DINTERVAL(2.,4.); A(1,2) = DINTERVAL(-2.,1.)
A(2,1) = DINTERVAL(-1.,2.); A(2,2) = DINTERVAL(2.,4.)

. . . . .
CALL DIGESVR( N, A, LDA, MSR, RSR, REG, INFO )
-----

```

Mutual disposition of the intervals `MSR` and `RSR` on the real axis can serve to some extent as a measure of how large the regularity margin is (in case of $MSR \geq RSR$), or how far the matrix is from the regular ones (in case of $MSR < RSR$).

Auxiliary and Utility Routines

?gemip

Performs midpoint-inverse preconditioning of an interval linear system.

Syntax

```
call sigemip(n, nrhs, a, lda, b, ldb, info)
call digemip(n, nrhs, a, lda, b, ldb, info)
call crgemip(n, nrhs, a, lda, b, ldb, info)
call zrgemip(n, nrhs, a, lda, b, ldb, info)
call ccgemip(n, nrhs, a, lda, b, ldb, info)
call zcgemip(n, nrhs, a, lda, b, ldb, info)
```

Description

The routine ?gemip performs midpoint-inverse preconditioning of the interval linear system $A \cdot X = B$. This is done through multiplying both matrices A and B by the midpoint-inverse matrix $\text{inv}(\text{mid } A)$ in computer (rounded) interval arithmetic.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A .
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a, b</i>	S_INTERVAL for sigemip. D_INTERVAL for digemip. CR_INTERVAL for crgemip. ZR_INTERVAL for zrgemip. CC_INTERVAL for ccgemip. ZC_INTERVAL for zcgemip. Arrays: <i>a</i> (<i>lda</i>, *), <i>b</i> (<i>ldb</i>, *). The array <i>a</i> contains the matrix A. The array <i>b</i> contains the matrix B, whose columns are the right-hand sides for the systems of equations.

The second dimension of a must be at least $\max(1, n)$ and the second dimension of b must be at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of a , $lda \geq \max(1, n)$.
 ldb INTEGER. The first dimension of b , $ldb \geq \max(1, n)$.

Output Parameters

a Overwritten by the preconditioned matrix A .
 b Overwritten by the preconditioned matrix B .
 $info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info \geq 1$, the execution is not successful.
 If $info = -i$, the i -th parameter has an illegal value.

Application Notes

Preconditioning may sometimes extend applicability of the algorithms for the solution of interval linear systems and/or improve the quality of the results produced by these algorithms.

In particular, interval Gauss method, interval Householder method and interval Gauss-Seidel iteration applied to interval linear systems with "wide" matrices that are not diagonally dominant should be preceded by preconditioning to yield better results. For Hansen-Bliek-Rohn procedure, the midpoint-inverse preconditioning is recommended if the middle matrix of the system is far from diagonal.

Example 12-4 Fortran 90 Code for Preconditioning Interval Linear System

The following piece of Fortran code presents an example of how you can perform preconditioning of the interval linear system

$$\begin{pmatrix} [2, 4] & [-2, 1] \\ [-1, 2] & [2, 4] \end{pmatrix} x = \begin{pmatrix} [0, 2] & [-2, 2] \\ [0, 2] & [-2, 2] \end{pmatrix}$$

and then solve it by using the interval Gauss method:

```

-----
. . . . .
USE INTERVAL_ARITHMETIC

. . . . .
TYPE(D_INTERVAL)           :: A(2,2), B(2,2)
INTEGER                    :: N = 2, NRHS = 2, LDA = 2, LDB = 2, INFO
CHARACTER(1)               :: TRANS = 'n'

. . . . .
A(1,1) = DINTERVAL(2.,4.);   A(1,2) = DINTERVAL(-2.,1.)
A(2,1) = DINTERVAL(-1.,2.);  A(2,2) = DINTERVAL(2.,4.)
B(1,1) = DINTERVAL(0.,2.);   B(2,1) = DINTERVAL(0.,2.)
B(1,2) = DINTERVAL(-2.,2.);  B(2,2) = DINTERVAL(-2.,2.)

. . . . .
CALL DIGEMIP( N, NRHS, A, LDA, B, LDB, INFO )
CALL DIGEGAS( TRANS, N, NRHS, A, LDA, B, LDB, INFO )
-----

```

For more code examples on using this routine, see in Appendix C of this manual .

Partial Differential Equations Support

13

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Library (see [Poisson Library Routines](#)).

Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the one that the Poisson Library provides. As it may be hard enough to modify the original code so as to make it work with Poisson Library, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Library routines can be called from C and Fortran 90, although the interfaces description uses C convention. Fortran 90 users can find routine calls specifics in the “[Calling PDE Support Routines from Fortran 90](#)” section.

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter “[Fast Fourier Transforms](#)”, Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel MKL TT interface, the C convention is used. Fortran users should refer to [Calling PDE Support Routines from Fortran 90](#).

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to *FFTW to Intel® MKL Wrappers Technical User Notes for FFTW 3.x* for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why

you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} \left[f(0) + f(n) \cos k\pi \right] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, \quad k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} \left[F(0) + F(n) \cos i\pi \right] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, \quad i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, \quad k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

NOTE. The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table 13-1](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

Table 13-1 TT Interface Routines

Routine	Description
<code>?_init_trig_transform</code>	Initializes basic data structures of Trigonometric Transforms.
<code>?_commit_trig_transform</code>	Checks consistency and correctness of user-defined data as well as creates a data structure to be used by Intel MKL FFT interface ¹ .
<code>?_forward_trig_transform</code> <code>?_backward_trig_transform</code>	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
<code>free_trig_transform</code>	Cleans the memory used by a data structure needed for calling FFT interface ¹ .

¹TT routines call Intel MKL FFT interface for better performance.

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table 13-1](#).

NOTE. Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure 13-1](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Figure 13-1 Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```

...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f ! If you want to preserve the data
stored in f,
save them before this place in your code */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...

```

You can find examples of Fortran 90 and C code that use TT interface routines to solve one-dimensional Helmholtz problem in the “[Trigonometric Transform Code Examples](#)” section in Appendix C.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the “[Trigonometric Transform Code Examples](#)” section in Appendix C).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING. To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE. If you need a copy of your input data arrays, save them yourself.

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform (int *n, int *tt_type, int ipar[], double dpar[],
int *stat);
```

```
void s_init_trig_transform (int *n, int *tt_type, int ipar[], float spar[],
int *stat);
```

Input Parameters

<i>n</i>	int*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size <i>n</i> +1 for all but staggered2 transforms. Staggered2 transforms require the vector of size <i>n</i> .
<i>tt_type</i>	int*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.

<code>dpar</code>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<code>spar</code>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.
<code>stat</code>	int*. Contains the routine completion status, which is also written to <code>ipar[6]</code> . The status should be 0 to proceed to other TT routines.

Description

The routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of `ipar` and `dpar` (`spar`) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array `ipar`. In the `dpar` or `spar` array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. You can skip calling the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

Return Values

<code>stat= 0</code>	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <code>stat</code> value.
<code>stat= -99999</code>	The routine failed to complete the task.

?_commit_trig_transform

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);

void s_commit_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle, int
ipar[], float spar[], int *stat);
```

Input Parameters

<i>f</i>	double for <code>d_commit_trig_transform</code>, float for <code>s_commit_trig_transform</code>, array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • $f[0]$ and $f[n]$ for sine transforms • $f[n]$ for staggered cosine transforms • $f[0]$ for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.

<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, the `?_commit_trig_transform` routine is mandatory, and you cannot skip calling it in your code.

Return Values

<i>stat</i> = 11	The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <i>ipar[6]</i> =0 if you are sure that the parameters are correct.
<i>stat</i> = 10	The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <i>ipar[6]</i> =0 if you are sure that the parameters are correct.
<i>stat</i> = 1	The routine produced some warnings. You may proceed with computations by assigning <i>ipar[6]</i> =0 if you are sure that the parameters are correct.
<i>stat</i> = 0	The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.

NOTE. Although positive values of *stat* usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve *stat*=0.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);
```

```
void s_forward_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], float spar[], int *stat);
```

Input Parameters

f

double for `d_forward_trig_transform`,
float for `s_forward_trig_transform`,
array of size *n* for staggered2 transforms and of size *n*+1
for all other transforms, where *n* is the size of the problem.
On input, contains data vector to be transformed. Note that
the following values should be 0.0 up to rounding errors:

- *f*[0] and *f*[*n*] for sine transforms

- $f[n]$ for staggered cosine transforms
- $f[0]$ for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the [Poisson Library Routines](#) section), which the TT interface is primarily designed for.

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”).
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine computes the forward Trigonometric Transform of type defined in the [?_init_trig_transform](#) routine and passed to [?_forward_trig_transform](#) with the *ipar* array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called [?_init_trig_transform](#) routine. The other data that facilitates the computation is created by [?_commit_trig_transform](#) and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the [?_commit_trig_transform](#) routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE. If you need a copy of the data vector f to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

Return Values

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because its commit step failed to complete or the parameter `ipar[0]` was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform (double f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], double dpar[], int *stat);
```

```
void s_backward_trig_transform (float f[], DFTI_DESCRIPTOR_HANDLE *handle,
int ipar[], float spar[], int *stat);
```

Input Parameters

f

double for `d_backward_trig_transform`,
float for `s_backward_trig_transform`,
array of size n for staggered2 transforms and of size $n+1$
for all other transforms, where n is the size of the problem.
On input, contains data vector to be transformed. Note that
the following values should be 0.0 up to rounding errors:

- $f[0]$ and $f[n]$ for sine transforms
- $f[n]$ for staggered cosine transforms
- $f[0]$ for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the [Poisson Library Routines](#) section), which the TT interface is primarily designed for.

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”).
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine computes the backward Trigonometric Transform of type defined in the [?_init_trig_transform](#) routine and passed to [?_backward_trig_transform](#) with the *ipar* array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called [?_init_trig_transform](#) routine. The other data that facilitates the computation is created by [?_commit_trig_transform](#) and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the

`?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector f with the transformed vector.

NOTE. If you need a copy of the data vector f to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

Return Values

`stat= 0`

The routine completed the task normally.

`stat= -100`

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.
- Data in `ipar`, `dpar` or `spar` parameters became incorrect and/or inconsistent as a result of modifications.

`stat= -1000`

The routine stopped because of an FFT interface error.

`stat= -10000`

The routine stopped because its commit step failed to complete or the parameter `ipar[0]` was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform (DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], int *stat);
```

Input Parameters

`ipar`

`int` array of size 128. Contains integer data needed for Trigonometric Transform computations.

handle DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”).

Output Parameters

handle The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.

ipar Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.

stat int*. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE. Initial values are assigned to the array parameters by the appropriate [?_init_trig_transform](#) and [?_commit_trig_transform](#) routines.

ipar int array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in [Table 13-2](#):

Table 13-2 Elements of the *ipar* Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <code>ipar[0]=n</code> , and all subsequently called TT routines use <code>ipar[0]</code> as the size of the transform.
1	Contains error messaging options: • <code>ipar[1]=-1</code> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <code>ipar[1]=0</code> indicates that no error messages will be printed. • <code>ipar[1]=1</code> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). In case of errors, each TT routine assigns a non-zero value to <code>stat</code> regardless of the <code>ipar[1]</code> setting.
2	Contains warning messaging options: • <code>ipar[2]=-1</code> indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <code>ipar[2]=0</code> indicates that no warning messages will be printed. • <code>ipar[2]=1</code> (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). In case of warnings, the <code>stat</code> parameter will acquire a non-zero value regardless of the <code>ipar[2]</code> setting.
3 through 4	Reserved for future use.
5	Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <code>ipar[5]=tt_type</code> , and all subsequently called TT routines use <code>ipar[5]</code> as the type of the transform.
6	Contains the <code>stat</code> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <code>stat=0</code> .

Index	Description
7	Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <code>dpar</code> (<code>spar</code>) and <code>handle</code>. <code>ipar[7]=0</code> indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1. The possibility to check correctness and consistency of input data without initializing data structures <code>dpar</code>, <code>spar</code> and <code>handle</code> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <code>ipar[7]</code> gives only if you are sure to have supplied proper tolerance value in the <code>dpar</code> or <code>spar</code> array. Otherwise, avoid tuning this parameter.
8	Contains message style options for TT routines. If <code>ipar[8]=0</code> then TT routines print all error and warning messages in Fortran-style notations. Otherwise, TT routines print the messages in C-style notations. The default value is 1. When selecting between these notations, mind that by default, numbering of elements in C arrays starts from 0 and in Fortran, it starts from 1. For example, for a C-style message "<i>parameter ipar[0]=3 should be an even integer</i>", the corresponding Fortran-style message will be "<i>parameter ipar(1)=3 should be an even integer</i>". The use of <code>ipar[8]</code> enables you to view messages in a more convenient style.
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Poisson Library. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications.
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in <i>FFTW to Intel® MKL Wrappers Technical User Notes for FFTW 3.x</i>. See also Caveat on Parameter Modifications.
11 through 127	Reserved for future use.

NOTE. You may declare the `ipar` array in your code as `int ipar[11]`. However, for compatibility with later versions of Intel MKL TT interface, which may require more `ipar` values, it is highly recommended to declare `ipar` as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	double array of size $5n/2+2$, holds data needed for double-precision routines to perform TT computations. This array is initialized in the <code>d_init_trig_transform</code> and <code>d_commit_trig_transform</code> routines.
<i>spar</i>	float array of size $5n/2+2$, holds data needed for single-precision routines to perform TT computations. This array is initialized in the <code>s_init_trig_transform</code> and <code>s_commit_trig_transform</code> routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table 13-3:

Table 13-3 Elements of the *dpar* and *spar* Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate <code>?_commit_trig_transform</code> routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The <code>?_commit_trig_transform</code> routine checks whether absolute values of these parameters are below $dpar[0]*n$ or $spar[0]*n$, depending on the routine precision. To suppress warnings resulting from tolerance checks, set $dpar[0]$ or $spar[0]$ to a sufficiently large number.
1	Reserved for future use.
2 through $5n/2+1$	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <i>tt_type</i>, set up in the <code>?_commit_trig_transform</code> routine: • If <i>tt_type</i>=MKL_SINE_TRANSFORM, the transform uses only the first $n/2$ array elements, which contain tabulated sine values. • If <i>tt_type</i>=MKL_STAGGERED_SINE_TRANSFORM, the transform uses only the first $3n/2$ array elements, which contain tabulated sine and cosine values. • If <i>tt_type</i>=MKL_STAGGERED2_SINE_TRANSFORM, the transform uses all the $5n/2$ array elements, which contain tabulated sine and cosine values. • If <i>tt_type</i>=MKL_COSINE_TRANSFORM, the transform uses only the first n array elements, which contain tabulated cosine values. • If <i>tt_type</i>=MKL_STAGGERED_COSINE_TRANSFORM, the transform uses only the first $3n/2$ elements, which contain tabulated sine and cosine values.

Index	Description
	If <code>tt_type=MKL_STAGGERED2_COSINE_TRANSFORM</code>, the transform uses all the $5n/2$ elements, which contain tabulated sine and cosine values.

NOTE. To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip calling the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of `ipar`, `dpar` and `spar` arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE. To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the `ipar`, `spar` and `dpar` arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/> .

WARNING. The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of `ipar`, `dpar` and `spar` arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the TT language-specific header files to include in their code. Currently, the following of them are available:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_trig_transforms.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE. Use of the Intel MKL TT software without including one of the above header files is not supported.

C-specific Header File

The C-specific header file defines the following function prototypes:

```
void d_init_trig_transform(int *, int *, int *, double *, int *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);

void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);

void s_init_trig_transform(int *, int *, int *, float *, int *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, int *, int *);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes:

```

SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_INIT_TRIG_TRANSFORM

SUBROUTINE D_COMMIT_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_COMMIT_TRIG_TRANSFORM

SUBROUTINE D_FORWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_FORWARD_TRIG_TRANSFORM

Fortran 90 specifics of the TT routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Poisson Library Routines

In addition to Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel® MKL supports the Poisson Library interface, referred to as PL interface. The interface implements a group of routines (PL routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems being solved are defined more exactly in the [Poisson Library Implemented](#) subsection. The PL interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The interface can adjust style of error and warning messages to C or Fortran notations by setting up a dedicated parameter. This adds convenience to debugging, because users can read information in the way that is natural for their code. The Intel MKL PL interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

To describe the Intel MKL PL interface, the C convention is used. Fortran usage specifics can be found in the [Calling PDE Support Routines from Fortran 90](#) section.

NOTE. Fortran users should mind that respective array indices in Fortran increase by 1.

Poisson Library Implemented

PL routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure 13-2](#) shows the general structure of the Poisson Library.

Figure 13-2 Structure of the Poisson Library

Sections below provide details of the problems that can be solved using Intel MKL PL.

Two-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x, a_y < y < b_y$ on a Cartesian plane:

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y\}, bd\_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y\}, bd\_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y , so that bd_+ denotes any of the above boundaries.

The PL interface description uses the following notation for boundaries of a rectangular domain $a_\phi < \phi < b_\phi, a_\theta < \theta < b_\theta$ on a sphere $0 \leq \phi \leq 2\pi, 0 \leq \theta \leq \pi$:

$$bd\_a_\phi = \{\phi = a_\phi, a_\theta \leq \theta \leq b_\theta\}, bd\_b_\phi = \{\phi = b_\phi, a_\theta \leq \theta \leq b_\theta\}$$

$$bd\_a_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = a_\theta\}, bd\_b_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols $a_\phi, b_\phi, a_\theta, b_\theta$, so that $bd\_~$ denotes any of the above boundaries.

Two-dimensional (2D) Helmholtz problem on a Cartesian plane

The 2D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), q = \text{const} \geq 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x, a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$n = -x$ on bd_a_x , $n = x$ on bd_b_x ,

$n = -y$ on bd_a_y , $n = y$ on bd_b_y .

Two-dimensional (2D) Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y)=0$. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary $bd_{\sim}$.

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = const \geq 0,$$
$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle that is, a domain bounded by angles $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$, with boundary conditions for particular domains listed in Table 13-4.

Table 13-4 Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\phi - a_\phi < 2 \pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary $bd_{\sim}$	<i>non-periodic</i>
Where $a_\phi = 0, b_\phi = 2 \pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries bd_{a_θ} and bd_{b_θ}	<i>periodic</i>
Entire sphere, that is, $a_\phi = 0, b_\phi = 2 \pi, a_\theta = 0$, and $b_\theta = \pi$	Boundary condition	<i>periodic</i>

$$\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\substack{\theta \rightarrow 0 \\ \theta \rightarrow \pi}} = 0$$

at the poles.

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$ in cases listed in [Table 13-4](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, a uniform mesh is built in the rectangular domain:

$$\left\{ x_i = a_x + ih_x, y_j = a_y + jh_y \right\},$$

$$i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

in the Cartesian case and

$$\left\{ \varphi_i = a_\varphi + ih_\varphi, \theta_j = a_\theta + jh_\theta \right\},$$

$$i = 0, \dots, n_\varphi, j = 0, \dots, n_\theta, h_\varphi = \frac{b_\varphi - a_\varphi}{n_\varphi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}$$

in the spherical case.

Poisson Library uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i, y_j) provided that the user knows the values of the right-hand side $f(x, y)$ in these points and the values of the appropriate boundary functions $G(x, y)$ and/or $g(x, y)$ in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (ϕ_i, θ_j) provided that the user knows the values of the right-hand side $f(\phi, \theta)$ in these points.

NOTE. The number of mesh intervals n_ϕ in the ϕ direction of a spherical mesh must be even in the periodic case. The current implementation of the Poisson Library does not support meshes with the number of intervals that does not meet this condition.

Three-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$:

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd\_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd\_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\}$$

$$bd\_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, bd\_b_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The wildcard "+" may stand for any of the symbols $a_x, b_x, a_y, b_y, a_z, b_z$, so that bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), q = \text{const} \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y, z) = G(x, y, z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd\_a_x, n = x \text{ on } bd\_b_x,$$

$$n = -y \text{ on } bd\_a_y, n = y \text{ on } bd\_b_y,$$

$$n = -z \text{ on } bd\_a_z, n = z \text{ on } bd\_b_z.$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with Dirichlet or Neumann boundary condition on each boundary $bd_{\pm}$.

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet or Neumann boundary condition on each boundary $bd_{\pm}$.

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh is built in the parallelepiped domain

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\}$$

where

$$i = 0, \dots, n_x, j = 0, \dots, n_y, k = 0, \dots, n_z$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}$$

The Poisson Library uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k) , provided that the user knows the values of the right-hand side $f(x, y, z)$ in these points and the values of the appropriate boundary functions $G(x, y, z)$ and/or $g(x, y, z)$ in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking PL Routines

NOTE. This description always considers the solution process for the Helmholtz problem, because Fast Poisson Solver and Fast Laplace Solver are special cases of Fast Helmholtz Solver (see [Poisson Library Implemented](#)).

Computation of a solution of the Helmholtz problem using the PL interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table 13-5](#) lists the routines and briefly describes their purpose.

Most PL routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names. The routines for Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "2D" and "3D". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "p" and "np"

Table 13-5 PL Interface Routines

Routine	Description
<code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np</code>	Initializes basic data structures of Poisson Library for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
<code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np</code>	Checks consistency and correctness of user's data, creates and initializes data structures to be used by the Intel MKL FFT interface ¹ , as well as other data structures needed for the solver.

Routine	Description
<code>?_Helmholtz_2D/?_Helmholtz_3D/ ?_sph_p/?_sph_np</code>	Computes an approximate solution of 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Library Implemented) specified by the parameters.
<code>free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/free_sph_np</code>	Cleans the memory used by the data structures needed for calling the Intel MKL FFT interface ¹ .

¹ PL routines call the Intel MKL FFT interface for better performance.

To find an approximate solution of Helmholtz problem only once, the Intel MKL PL interface routines are normally invoked in the order in which they are listed in [Table 13-5](#).

NOTE. Though the order of invoking PL routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure 13-3](#) indicates the typical order in which PL routines can be invoked in a general case.

Figure 13-3 Typical Order of Invoking PL Routines

A general scheme of using PL routines for double-precision computations in a 3D Cartesian case is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a 2D Cartesian case differs from the one below in the set of routine parameters and the ending of routine names: "2D" instead of "3D".

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, Bctype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to keep the
data stored in f,
save it before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar,
dpar, &stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using PL routines for double-precision computations in a spherical periodic case is shown below. Similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a spherical non-periodic case differs from the one below in the set of routine parameters and the ending of routine names: "np" instead of "p".

```
...
d_init_sph_p(&ap, &bp, &at, &bt, &np, &nt, &q, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to
keep the data stored in f, save it before the function call below */
d_commit_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
d_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
free_sph_p(&handle_s, &handle_c, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of Fortran 90 and C code that use PL routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the “[Poisson Library Code Examples](#)” section in Appendix C.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the “[Poisson Library Code Examples](#)” section in Appendix C).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All PL routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING. To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

PL routines take arrays of user data as input. For example, user arrays are passed to the routine `d_Helmholtz_3D` to compute an approximate solution to 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL PL routines do not make copies of user input arrays.

NOTE. If you need a copy of your input data arrays, save them yourself.

PL Routines for the Cartesian Solver

The section gives detailed description of Cartesian PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, 2D and 3D, are described together.

NOTE. Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

PL routines call the Intel MKL FFT interface (described in section “[FFT Functions](#)” in chapter “Fast Fourier Transforms”), which enhances performance of the routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D(double* ax, double* bx, double* ay, double* by,
int* nx, int* ny, char* BCtype, double* q, int* ipar, double* dpar, int*
stat);

void s_init_Helmholtz_2D(float* ax, float* bx, float* ay, float* by, int*
nx, int* ny, char* BCtype, float* q, int* ipar, float* spar, int* stat);

void d_init_Helmholtz_3D(double* ax, double* bx, double* ay, double* by,
double* az, double* bz, int* nx, int* ny, int* nz, char* BCtype, double* q,
int* ipar, double* dpar, int* stat);

void s_init_Helmholtz_3D(float* ax, float* bx, float* ay, float* by, float*
az, float* bz, int* nx, int* ny, int* nz, char* BCtype, float* q, int* ipar,
float* spar, int* stat);
```

Input Parameters

<code>ax</code>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along x-axis.

<i>bx</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along x-axis.
<i>ay</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along y-axis.
<i>by</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along y-axis.
<i>az</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>bz</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>nx</i>	int*. The number of mesh intervals along x-axis.
<i>ny</i>	int*. The number of mesh intervals along y-axis.
<i>nz</i>	int*. The number of mesh intervals along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>BCtype</i>	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition) or 'D' (Dirichlet boundary

condition). Types of boundary conditions for the boundaries should be specified in the following order: *bd_ax*, *bd_bx*, *bd_ay*, *bd_by*, *bd_az*, *bd_bz*. Boundary condition types for the last two boundaries should be specified only in the 3D case.

q double* for
 d_init_Helmholtz_2D/d_init_Helmholtz_3D,
 float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D

.
 The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of *q* to 0.

Output Parameters

ipar int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

dpar double array of size $5 \cdot n_x / 2 + 7$ in the 2D case or $5 \cdot (n_x + n_y) / 2 + 9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

spar float array of size $5 \cdot n_x / 2 + 7$ in the 2D case or $5 \cdot (n_x + n_y) / 2 + 9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to [Common Parameters](#)).

stat int*. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The routines `?_init_Helmholtz_2D/?_init_Helmholtz_3D` are called to initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING. Data structures initialized and created by 2D/3D flavors of the routine cannot be used by 3D/2D flavors of any PL routines, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

`stat= 0`

The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this `stat` value.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

?_commit_Helmholtz_2D/?_commit_Helmholtz_3D

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double*
bd_ay, double* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, double* dpar, int*
stat);
```

```
void s_commit_Helmholtz_2D (float* f, float* bd_ax, float* bd_bx, float*
bd_ay, float* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, float* spar, int*
stat);
```

```
void d_commit_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double*
bd_ay, double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_commit_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float*
bd_ay, float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, float* spar, int* stat);
```

Input Parameters

<i>f</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains the right-hand side of the problem packed in a single vector. The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, the value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$. The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$. Note that to solve the Laplace problem, you should set all the elements of the array <i>f</i> to 0. Note also that the array <i>f</i> may be altered by the routine. To preserve the vector, save it in another memory location.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>bd_ax</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along <i>x</i>-axis.

For `?_commit_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_ax[j]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[0]` is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[0]` is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_ax[j+k*(ny+1)]`.

`bd_bx`

`double* for`
`d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for`
`s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`
 Contains values of the boundary condition on the rightmost boundary of the domain along x -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in `bd_bx[j]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[1]` is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[1]` is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in `bd_bx[j+k*(ny+1)]`.

bd_ay

double* for
d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,
float* for
s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
Contains values of the boundary condition on the leftmost boundary of the domain along *y*-axis.
For ?_commit_Helmholtz_2D, the size of the array is *nx*+1. In case of the Dirichlet boundary condition (value of *BCtype*[2] is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of *BCtype*[2] is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index *i* is placed in *bd_ay*[*i*].
For ?_commit_Helmholtz_3D, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of *BCtype*[2] is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx, k=0, \dots, nz$. In case of the Neumann boundary condition (value of *BCtype*[2] is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (*i, k*) is placed in *bd_ay*[*i+k*(nx+1)*].

bd_by

double* for
d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,
float* for
s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
Contains values of the boundary condition on the rightmost boundary of the domain along *y*-axis.
For ?_commit_Helmholtz_2D, the size of the array is *nx*+1. In case of the Dirichlet boundary condition (value of *BCtype*[3] is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of *BCtype*[3] is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index *i* is placed in *bd_by*[*i*].
For ?_commit_Helmholtz_3D, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of *BCtype*[3] is 'D'), it contains values of the function

$G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCType[3]` is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_by[i+k*(nx+1)]`.

`bd_az`

`double* for`
`d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for`
`s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`
 This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.
 The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCType[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCType[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i+j*(nx+1)]`.

`bd_bz`

`double* for`
`d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for`
`s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`
 This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis.
 The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCType[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCType[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i+j*(nx+1)]`.

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>xhandle, yhandle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>yhandle</i> is used only by <code>?_commit_Helmholtz_3D</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` check consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize data structures *xhandle, yhandle* as well as arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, the routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` are mandatory, and you cannot skip calling them in your code. Values of *ax, bx, ay, by, az, bz, nx, ny, nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

<code>stat= 1</code>	The routine completed without errors and produced some warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the user's data was found or the data in the <code>dpar</code> , <code>spar</code> or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

?_Helmholtz_2D/?_Helmholtz_3D

Computes the solution of 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, double* dpar, int* stat);
void s_Helmholtz_2D (float* f, float* bd_ax, float* bd_bx, float* bd_ay,
float* bd_by, DFTI_DESCRIPTOR* xhandle, int* ipar, float* spar, int* stat);
void d_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, double* dpar, int* stat);
void s_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay,
float* bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR* xhandle,
DFTI_DESCRIPTOR* yhandle, int* ipar, float* spar, int* stat);
```

Input Parameters

<code>f</code>	double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate

[?_commit_Helmholtz_2D/?_commit_Helmholtz_3D](#) routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution.

The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$. The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$.

<i>xhandle, yhandle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>yhandle</i> is used only by ?_Helmholtz_3D .
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>bd_ax</i>	double* for d_Helmholtz_2D/d_Helmholtz_3D , float* for s_Helmholtz_2D/s_Helmholtz_3D . Contains values of the boundary condition on the leftmost boundary of the domain along x-axis. For ?_Helmholtz_2D , the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of BCtype[0] is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value

of $BCType[0]$ is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in $bd\_ax[j]$.

For $?\_Helmholtz\_3D$, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCType[0]$ is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCType[0]$ is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in $bd\_ax[j+k*(ny+1)]$.

bd_bx

double* for $d\_Helmholtz\_2D/d\_Helmholtz\_3D$,
float* for $s\_Helmholtz\_2D/s\_Helmholtz\_3D$.

Contains values of the boundary condition on the rightmost boundary of the domain along x -axis.

For $?\_Helmholtz\_2D$, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of $BCType[1]$ is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of $BCType[1]$ is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in $bd\_bx[j]$.

For $?\_Helmholtz\_3D$, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCType[1]$ is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCType[1]$ is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in $bd\_bx[j+k*(ny+1)]$.

bd_ay

double* for $d\_Helmholtz\_2D/d\_Helmholtz\_3D$,
float* for $s\_Helmholtz\_2D/s\_Helmholtz\_3D$.

Contains values of the boundary condition on the leftmost boundary of the domain along y -axis.

For `?_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCtype[2]` is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_ay[i]`.

For `?_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[2]` is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_ay[i+k*(nx+1)]`.

`bd_by`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`

Contains values of the boundary condition on the rightmost boundary of the domain along y -axis.

For `?_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[3]` is 'D'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCtype[3]` is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_by[i]`.

For `?_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[3]` is 'D'), it contains values of the function $G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[3]` is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_by[i+k*(nx+1)]`.

`bd_az`

`double* for d_Helmholtz_2D/d_Helmholtz_3D,`

`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 This parameter is needed only for `?_Helmholtz_3D`.
 Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.
 The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i+j*(nx+1)]`.

`bd_bz` `double* for d_Helmholtz_2D/d_Helmholtz_3D,`
`float* for s_Helmholtz_2D/s_Helmholtz_3D.`
 This parameter is needed only for `?_Helmholtz_3D`.
 Contains values of the boundary condition on the rightmost boundary of the domain along z -axis.
 The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i+j*(nx+1)]`.

NOTE. To avoid wrong computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

`f` On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.

`xhandle, yhandle` Data structures used by the Intel MKL FFT interface.

<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>stat</i>	<code>int*</code> . Routine completion status, which is also written to <i>ipar</i> [0]. The status should be 0 to proceed to other PL routines.

Description

The routines compute the approximate solution of Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *ax*, *bx*, *ay*, *by*, *az*, *bz*, *nx*, *ny*, *nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of the Intel MKL FFT or TT interface error.

`stat= -10000`

The routine stopped because the initialization failed to complete or the parameter `ipar[0]` was altered by mistake.

`stat= -99999`

The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR* xhandle, int* ipar, int* stat);
void free_Helmholtz_3D (DFTI_DESCRIPTOR* xhandle, DFTI_DESCRIPTOR* yhandle,
int* ipar, int* stat);
```

Input Parameters

<code>xhandle, yhandle</code>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). The structure <code>yhandle</code> is used only by <code>free_Helmholtz_3D</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

Output Parameters

<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Status of the routine call is written to <code>ipar[0]</code> .
<code>stat</code>	int*. Routine completion status, which is also written to <code>ipar[0]</code> .

Description

The routine cleans the memory used by the *xhandle* and *yhandle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

PL Routines for the Spherical Solver

The section gives detailed description of spherical PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, periodic (having names ending in "p") and non-periodic (having names ending in "np"), are described together.

These PL routines also call the Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the Fast periodic and non-periodic Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p(double* ap, double* at, double* bp, double* bt, int* np,
int* nt, double* q, int* ipar, double* dpar, int* stat);

void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int*
nt, float* q, int* ipar, float* spar, int* stat);

void d_init_sph_np(double* ap, double* at, double* bp, double* bt, int* np,
int* nt, double* q, int* ipar, double* dpar, int* stat);

void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int*
nt, float* q, int* ipar, float* spar, int* stat);
```

Input Parameters

<i>ap</i>	double* for <code>d_init_sph_p/d_init_sph_np</code> , float* for <code>s_init_sph_p/s_init_sph_np</code> . The coordinate (angle) of the leftmost boundary of the domain along ϕ -axis.
<i>bp</i>	double* for <code>d_init_sph_p/d_init_sph_np</code> , float* for <code>s_init_sph_p/s_init_sph_np</code> . The coordinate (angle) of the rightmost boundary of the domain along ϕ -axis.
<i>at</i>	double* for <code>d_init_sph_p/d_init_sph_np</code> , float* for <code>s_init_sph_p/s_init_sph_np</code> . The coordinate (angle) of the leftmost boundary of the domain along θ -axis.
<i>bt</i>	double* for <code>d_init_sph_p/d_init_sph_np</code> , float* for <code>s_init_sph_p/s_init_sph_np</code> . The coordinate (angle) of the rightmost boundary of the domain along θ -axis.
<i>np</i>	int*. The number of mesh intervals along ϕ -axis. Must be even in the periodic case.
<i>nt</i>	int*. The number of mesh intervals along θ -axis.
<i>q</i>	double* for <code>d_init_sph_p/d_init_sph_np</code> , float* for <code>s_init_sph_p/s_init_sph_np</code> . The constant Helmholtz coefficient. Note that to solve Poisson problem, you should set the value of <i>q</i> to 0.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

<i>spar</i>	float array of size $5 \cdot np/2 + nt + 10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines `?_init_sph_p/?_init_sph_np` are called to initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING. Data structures initialized and created by periodic/non-periodic flavors of the routine cannot be used by non-periodic/periodic flavors of any PL routines for Helmholtz Solver on a sphere, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

?_commit_sph_p/?_commit_sph_np

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR*
handle_c, int* ipar, double* dpar, int* stat);

void s_commit_sph_p(float* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR*
handle_c, int* ipar, float* spar, int* stat);

void d_commit_sph_np(double* f, DFTI_DESCRIPTOR* handle, int* ipar, double*
dpar, int* stat);

void s_commit_sph_np(float* f, DFTI_DESCRIPTOR* handle, int* ipar, float*
spar, int* stat);
```

Input Parameters

<i>f</i>	double* for d_commit_sph_p/d_commit_sph_np, float* for s_commit_sph_p/s_commit_sph_np. Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(n_p+1)*(n_t+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(n_p+1)]$. Note that the array <i>f</i> may be altered by the routine. Please save this vector in another memory location if you want to preserve it.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*n_p/2+n_t+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*n_p/2+n_t+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar</i> [0]. The status should be 0 to proceed to other PL routines.

Description

The routines `?_commit_sph_p/?_commit_sph_np` check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle_s* and *handle_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_sph_p/?_init_sph_np`, the routines `?_commit_sph_p/?_commit_sph_np` are mandatory, and you cannot skip calling them in your code. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

<code>stat= 1</code>	The routine completed without errors and produced some warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the user's data was found or the data in the <code>dpar</code> , <code>spar</code> or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

?_sph_p/?_sph_np

Computes the solution of a spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c,
int* ipar, double* dpar, int* stat);

void s_sph_p(float* f, DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c,
int* ipar, float* spar, int* stat);

void d_sph_np(double* f, DFTI_DESCRIPTOR* handle, int* ipar, double* dpar,
int* stat);

void s_sph_np(float* f, DFTI_DESCRIPTOR* handle, int* ipar, float* spar, int*
stat);
```

Input Parameters

`f` double* for `d_sph_p/d_sph_np`,
 float* for `s_sph_p/s_sph_np`.

Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_sph_p/?_commit_sph_np` routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$.

<i>handle_s, handle_c, handle</i>	DESCRIPTOR_HANDLE*. Data structures used by Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_sph_p</code> and <i>handle</i> is used only in <code>?_sph_np</code> .
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>f</i>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<i>handle_s, handle_c, handle</i>	Data structures used by the Intel MKL FFT interface.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .

<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>stat</i>	<code>int*</code> . Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -10000	The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR* handle_s, DFTI_DESCRIPTOR* handle_c, int*
ipar, int* stat);

void free_sph_np(DFTI_DESCRIPTOR* handle, int* ipar, int* stat);
```

Input Parameters

<i>handle_s, handle_c,</i> <i>handle</i>	DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section “ FFT Functions ” in chapter “Fast Fourier Transforms”). The structures <i>handle_s</i> and <i>handle_c</i> are used only in <i>free_sph_p</i> , and <i>handle</i> is used only in <i>free_sph_np</i> .
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>handle_s, handle_c,</i> <i>handle</i>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> .

Description

The routine cleans the memory used by the *handle_s*, *handle_c* or *handle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine successfully completed the task.

<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

Common Parameters

This section provides description of array parameters *ipar*, *dpar* and *spar*, which hold PL routine options in both Cartesian and spherical cases.

NOTE. Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

<i>ipar</i>	int array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table 13-6 :

Table 13-6 Elements of the ipar Array

Index	Description
0	Contains status value of the last called PL routine. In general, it should be 0 to proceed with Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see Figure 13-3). A non-zero value of <code>ipar[0]</code> with decimal representation

$$\overline{abc} = 100a + 10b + c$$

where each of *a*, *b*, and *c* is equal to 0 or 9, indicates that some parts of the Commit step should be omitted.

- If *c*=9, the routine omits checking of parameters and initialization of the data structures.

Index	Description
	• If $b=9$, then in the Cartesian case, the routine omits the adjustment of the right-hand side vector f to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function g) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function g). In this case, the routine also omits the adjustment of the right-hand side vector f to the particular boundary functions. For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the $dpar/spar$ array. • If $a=9$, then the routine omits the normalization of the right-hand side vector f. In the 2D Cartesian case, it is the multiplication by h_y^2, where h_y is the mesh size in the y direction (for details, see Poisson Library Implemented). In the 3D (Cartesian) case, it is the multiplication by h_z^2, where h_z is the mesh size in the z direction. For the Helmholtz solver on a sphere, it is the multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Library Implemented).

Using `ipar[0]` you can adjust the routine to your needs and gain efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious using this opportunity, because misunderstanding of the commit process may cause wrong results or program failure (see also [Caveat on Parameter Modifications](#)).

- 1 Contains error messaging options:
 - `ipar[1]=-1` indicates that all error messages will be printed to the file `MKL_Poisson_Library_log.txt` in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.
 - `ipar[1]=0` indicates that no error messages will be printed.
 - `ipar[1]=1` is the default value. It indicates that all error messages will be printed to the preconnected default output device (usually, screen).

In case of errors, the `stat` parameter will acquire a non-zero value regardless of the `ipar[1]` setting.

- 2 Contains warning messaging options:

Index	Description
	• <code>ipar[2]=-1</code> indicates that all warning messages will be printed to the file <code>MKL_Poisson_Library_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <code>ipar[2]=0</code> indicates that no warning messages will be printed. • <code>ipar[2]=1</code> is the default value. It indicates that all warning messages will be printed to the preconnected default output device (usually, screen). In case of warnings, the <code>stat</code> parameter will acquire a non-zero value regardless of the <code>ipar[2]</code> setting.
3	Contains the number of the combination of boundary conditions. In the Cartesian case, it corresponds to the value that the <code>BCtype</code> parameter holds: • In the 2D case, 0 corresponds to 'DDDD' 1 corresponds to 'DDDN' ... 15 corresponds to 'NNNN' • In the 3D case, 0 corresponds to 'DDDDDD' 1 corresponds to 'DDDDDN' ... 63 corresponds to 'NNNNNNN'. The Helmholtz solver on a sphere uses this parameter only in a periodic case. The <code>bp</code> and <code>bt</code> parameters of the <code>?_init_sph_p/?_init_sph_np</code> routine, which initializes <code>ipar[3]</code>, determine its value: • 0 corresponds to the problem without poles. • 1 corresponds to the problem on the entire sphere.
Parameters 4 through 9 are used only in Cartesian case.	
4	Takes the value of 1 if <code>BCtype[0]='N'</code> , 0 if <code>BCtype[0]='D'</code> , and -1 otherwise.
5	Takes the value of 1 if <code>BCtype[1]='N'</code> , 0 if <code>BCtype[1]='D'</code> , and -1 otherwise.

Index	Description
6	Takes the value of 1 if <i>BCTYPE</i> [2]='N', 0 if <i>BCTYPE</i> [2]='D', and -1 otherwise.
7	Takes the value of 1 if <i>BCTYPE</i> [3]='N', 0 if <i>BCTYPE</i> [3]='D', and -1 otherwise.
8	Takes the value of 1 if <i>BCTYPE</i> [4]='N', 0 if <i>BCTYPE</i> [4]='D', and -1 otherwise. This parameter is used only in the 3D case.
9	Takes the value of 1 if <i>BCTYPE</i> [5]='N', 0 if <i>BCTYPE</i> [5]='D', and -1 otherwise. This parameter is used only in the 3D case.
10	Takes the value of <i>nx</i>, that is, the number of intervals along <i>x</i>-axis, in the Cartesian case. <i>np</i>, that is, the number of intervals along ϕ-axis, in the spherical case.
11	Takes the value of <i>ny</i>, that is, the number of intervals along <i>y</i>-axis, in the Cartesian case <i>nt</i>, that is, the number of intervals along θ-axis, in the spherical case.
12	Takes the value of <i>nz</i> , the number of intervals along <i>z</i> -axis. This parameter is used only in the 3D case (Cartesian).
13	Takes the value of 6, which specifies the internal partitioning of the <i>dpar/spar</i> array.
14	Takes the value of <i>ipar</i> [13]+ <i>ipar</i> [10]+1, which specifies the internal partitioning of the <i>dpar/spar</i> array.

Subsequent values of *ipar* depend upon the dimension of the problem or upon whether the solver on a sphere is periodic.

	2D case	3D case	Periodic case	Non-periodic case
15	Unused	Takes the value of <i>ipar</i> [14]+1, which specifies the internal partitioning of the <i>dpar/spar</i> array.		
16	Unused	Takes the value of <i>ipar</i> [14]+ <i>ipar</i> [11]+1, which specifies the internal partitioning of the <i>dpar/spar</i> array.		

Index	Description			
17	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		
18	Takes the value of $ipar[14]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/4+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.
19	Unused	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.		Unused
20	Unused	Takes the value of $ipar[18]+3*ipar[11]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[18]+3*ipar[10]/4+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Unused

Subsequent values of *ipar* are assigned regardless.

21	Contains message style options: • $ipar[21]=0$ indicates that PL routines print all error and warning messages in Fortran-style notations. • $ipar[21]=1$ (default) indicates that PL routines print the messages in C-style notations.
22	Contains the number of threads to be used for computations in a multithreaded environment. The default value is 1.

Index	Description
23 through 39	Unused in the current implementation of the Poisson Library.
40 through 59	Contain the first twenty elements of the <i>ipar</i> array of the first Trigonometric Transform that the Solver uses. (For details, see Common Parameters in the “Trigonometric Transform Routines” chapter.)
60 through 79	Contain the first twenty elements of the <i>ipar</i> array of the second Trigonometric Transform that the 3D and periodic solvers use. (For details, see Common Parameters in the “Trigonometric Transform Routines” chapter.)

NOTE. You may declare the *ipar* array in your code as `int ipar[80]`. However, for compatibility with later versions of Intel MKL Poisson Library, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	Holds data needed for double-precision Fast Helmholtz Solver computations. - For the Cartesian solver, double array of size $5 \cdot n_x/2 + 7$ in the 2D case or $5 \cdot (n_x + n_y)/2 + 9$ in the 3D case; initialized in the <code>d_init_Helmholtz_2D/d_init_Helmholtz_3D</code> and <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> routines. - For the spherical solver, double array of size $5 \cdot n_p/2 + n_t + 10$; initialized in the <code>d_init_sph_p/d_init_sph_np</code> and <code>d_commit_sph_p/d_commit_sph_np</code> routines.
<i>spar</i>	Holds data needed for single-precision Fast Helmholtz Solver computations. - For the Cartesian solver, float array of size $5 \cdot n_x/2 + 7$ in the 2D case or $5 \cdot (n_x + n_y)/2 + 9$ in the 3D case; initialized in the <code>s_init_Helmholtz_2D/s_init_Helmholtz_3D</code> and <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> routines. - For the spherical solver, float array of size $5 \cdot n_p/2 + n_t + 10$; initialized in the <code>s_init_sph_p/s_init_sph_np</code> and <code>s_commit_sph_p/s_commit_sph_np</code> routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table 13-7:

Table 13-7 Elements of the *dpar* and *spar* Arrays

Index	Description
0	In the Cartesian case, contains the length of the interval along x-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_x in the x direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the spherical case, contains the length of the interval along ϕ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_ϕ in the ϕ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
1	In the Cartesian case, contains the length of the interval along y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_y in the y direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the spherical case, contains the length of the interval along θ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_θ in the θ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
2	In the Cartesian case, contains the length of the interval along z-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_z in the z direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case. In the spherical solver, contains the coordinate of the leftmost boundary along θ-axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.
3	Contains the value of the coefficient q after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.

Index	Description
4	Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine. - In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<code>BType="NNNN"</code> in the 2D case; <code>BType="NNNNNN"</code> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. Poisson Library verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, Poisson Library computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs the user that the solution may not exist in a classical sense (up to rounding errors). - In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the above described Cartesian case with pure Neumann boundary conditions. So, here Poisson Library computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.
<code>ipar[13]-1</code> through <code>ipar[14]-1</code>	In the Cartesian case, contain the spectrum of the 1D problem along x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the spherical case, contains the spectrum of the 1D problem along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
<code>ipar[15]-1</code> through <code>ipar[16]-1</code>	In the Cartesian case, contain the spectrum of the 1D problem along y-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case. In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.

Index	Description
<i>ipar</i> [17]-1 through <i>ipar</i> [18]-1	Take the values of the (staggered) sine/cosine in the mesh points: • along <i>x</i>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver • along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver.
<i>ipar</i> [19]-1 through <i>ipar</i> [20]-1	Take the values of the (staggered) sine/cosine in the mesh points: • along <i>y</i>-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver • along ϕ-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver. These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.

NOTE. You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the PL interface enables you to skip calling the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE. To supply correct and consistent parameters to PL routines, you should have considerable experience in using the PL interface and good understanding of the solution process as well as elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail in tuning parameters for the Fast Helmholtz Solver. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING. The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL PL interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the PL language-specific header files to include in their code. Currently, the following header files are available:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_poisson.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE. Use of the Intel MKL PL software without including one of the above header files is not supported.

The include files define function prototypes for appropriate languages.

C-specific Header File

The C-specific header file defines the following function prototypes for the Cartesian solver:

```
void d_init_Helmholtz_2D(double*, double*, double*, double*, int*, int*, char*, double*,
int*, double*, int*);

void d_commit_Helmholtz_2D(double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*,
int*, double*, int*);

void s_init_Helmholtz_2D(float*, float*, float*, float*, int*, int*, char*, float*, int*,
float*, int*);

void s_commit_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*,
int*, float*, int*);

void s_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*,
float*, int*);

void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_Helmholtz_3D(double*, double*, double*, double*, double*, double*, int*, int*,
int*, char*, double*, int*, double*, int*);

void d_commit_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_Helmholtz_3D(float*, float*, float*, float*, float*, float*, int*, int*, int*,
char*, float*, int*, float*, int*);

void s_commit_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void s_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

The C-specific header file defines the following function prototypes for the spherical solver:

```
void d_init_sph_p(double*, double*, double*, double*, int*, int*, double*, int*, double*,
int*);

void d_commit_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*,
int*);

void d_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*,
int*);
```

```
void s_init_sph_p(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);
void s_commit_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*,
int*);
void s_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);
void free_sph_p(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);
void d_init_sph_np(double*, double*, double*, double*, int*, int*, double*, int*, double*,
int*);
void d_commit_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);
void d_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);
void s_init_sph_np(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);
void s_commit_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);
void s_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);
void free_sph_np(DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes for the Cartesian solver:

```
SUBROUTINE D_INIT_HELMHOLTZ_2D (AX, BX, AY, BY, NX, NY, BCTYPE, Q, IPAR, DPAR, STAT)

Fortran 90 specifics of the PL routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Calling PDE Support Routines from Fortran 90

The calling interface for all the Intel MKL TT and PL routines is designed to be easily used in C. However, you can invoke each TT or PL routine directly from Fortran 90 if you are familiar with the inter-language calling conventions of your platform.

The TT or PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of the Intel MKL FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran 90 and how C external names are decorated on the platform.

To promote portability and relieve a user of dealing with the calling conventions specifics, Fortran 90 header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for PL routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran 90.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length `n`. C users access such a function as follows:

```
int n;

double *x;

...

foo(x, &n);
```

As noted above, to invoke `foo`, Fortran 90 users would need to know what Fortran 90 data types correspond to C types `int` and `double` (or `float` in case of single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran 90 header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran 90 program will look as follows:

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms

INTEGER n

DOUBLE PRECISION, ALLOCATABLE :: x

...

CALL FOO(x,n)
```

- For PL interface,

```
use mkl_dfti
use mkl_poisson

INTEGER n

DOUBLE PRECISION, ALLOCATABLE :: x

...

CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of PL or TT routines in Fortran 90, the general approach of providing Fortran 90 definitions of names is used throughout the libraries. Specifically, if a name from a PL or TT interface is documented as having the C-specific name `foo`, then the Fortran 90 header files provide an appropriate Fortran 90 language type definition `FOO`.

One of the key differences between Fortran 90 and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran 90 programs use pass-by-reference semantics. The Fortran 90 headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Optimization Solver Routines

Intel® Math Kernel Library provides tools for solving optimization problems. These tools are routines for solving nonlinear least squares problems through the Trust-Region (TR) algorithms.

Intel MKL provides the optimization solver routines that can be used for:

- solving nonlinear least squares problems without constraints
- solving nonlinear least squares problems with boundary constraints
- computing the Jacobi matrix by central differences for solving nonlinear least squares problem

The first two groups of routines are designed to find only one local minimum point. However problems can have multiple local minima and trying different initial points is recommended for better solutions.

For more information on terms and key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [Appendix F, “Optimization Solvers Basics”](#).

Routines described below are subdivided according to their purpose as follows:

[Nonlinear Least Squares Problem without Constraints](#)

[Nonlinear Least Squares Problem with Linear \(Boundary\) Constraints](#)

[Jacobi Matrix Calculation Routines](#).

Organization and Implementation

The TR solvers have RCI-based interfaces. The RCI TR interface implements a group of user-callable routines that are used in the step-by-step solving process for nonlinear least squares problem and follows the general RCI scheme described in [[Dong95](#)]. RCI means that the user is supposed to perform certain operations for the solver, for example, to provide values of the objective function

or a Jacobi matrix. When the solver needs the results of such operations, the user should pass them to the solver. This makes the solver independent of specific implementation of the operations. However, this approach requires some additional work by the user.

Figure 14-1 Typical order for invoking RCI solver routines

The Trust-Region solvers are implemented with OpenMP* support. To use the multiprocessing mode, set the number of threads in environment variable `OMP_NUM_THREADS`.

Memory Allocation and Handles

To make the routines easy to use, you are not required to allocate temporary working storage. Any required memory is allocated by the solver. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using an opaque data object called a *handle*. Each of the Intel RCI TR solver routine creates, uses or deletes a handle.

Handle declaration varies from language to language. This document declares it as to be of `_TRNSP_HANDLE_t` or `_TRNSPBC_HANDLE_t` type.

C and C++ programmers should declare a handle as:

```
#include "mkl_rci.h"

_TRNSP_HANDLE_t handle;

or

_TRNSPBC_HANDLE_t handle;
```

Fortran programmers using compilers that support eight byte integers should declare a handle as:

```
INCLUDE "mkl_rci.fi"

INTEGER*8 handle
```

In addition to the necessary definition, for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the error returns
- user options for the solver routines
- message severity.

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in R^n} F(x) = \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m > n,$$

where $F(x) : R^n \rightarrow R$ is a twice differentiable function in R^n . Solving of the nonlinear least squares problem is searching for the best approximation to vector y with model function $f_i(x)$, which has nonlinear dependence on variables x . The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the lowest possible.

Table 14-1 RCI TR Routines

Routine Name	Operation
dtrnlsp_init	Initializes the solver.

Routine Name	Operation
<code>dtrnlsp_solve</code>	Solves a nonlinear least squares problem on the basis of RCI using the Trust-Region algorithm.
<code>dtrnlsp_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>dtrnlsp_delete</code>	Removes data.

dtrnlsp_init

Initializes the solver of nonlinear least squares problem.

Syntax

Fortran:

```
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

C:

```
res = dtrnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
```

Description

The routine initializes the solver. After initialization all subsequent invocations of the `dtrnlsp_solve` routine should use the values of the handle returned by `dtrnlsp_init`.

The *eps* array contains the stopping tests:

eps(1): $\Delta_k < \text{eps}(1)$

eps(2): $\|F(x)\| < \text{eps}(2)$

eps(3): $\|A(x)_{ij}\| < \text{eps}(3)$

eps(4): $\|s\| < \text{eps}(4)$

eps(5): $\|F(x)\| - \|F(x) - A(x)s\| < \text{eps}(5)$

eps(6): the trial step precision. If *eps*(6) = 0, then *eps*(6) = 1.d-10,

where *A* is the Jacobi matrix, Δ_k is the trust region area, *F*(*x*) is the value of the functional, *s* is the trial step.

Input Parameters

<i>n</i>	INTEGER. Length of x .
<i>m</i>	INTEGER. Length of $F(x)$.
<i>x</i>	DOUBLE PRECISION. Array of size n . Initial guess.
<i>eps</i>	DOUBLE PRECISION. Array of size 6; contains stopping tests. See the values in Description.
<i>iter1</i>	INTEGER. Specifies the maximum number of iterations.
<i>iter2</i>	INTEGER. Specifies the maximum number of iterations of trial-step calculation.
<i>rs</i>	DOUBLE PRECISION. Positive input variable used in determining the initial step bound. In most cases the factor should lie within the interval (0.1, 100.0). The generally recommended value is 100.

Output Parameters

<i>handle</i>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> means the routine completed the task normally. <i>res</i> = <code>TR_INVALID_OPTION</code> means an error in the input parameters. <i>res</i> = <code>TR_OUT_OF_MEMORY</code> means a memory error.

dtrnlsp_solve

Solves a nonlinear least squares problem using the Trust-Region algorithm.

Syntax

Fortran:

```
res = dtrnlsp_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = dtrnlsp_solve(&handle, fvec, fjac, &RCI_Request);
```

Description

The `dtrnlsp_solve` routine, based on Reverse Communication Interface (RCI), uses the Trust-Region algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} F(x)^T F(x) = \frac{1}{2} \sum_{i=1}^m f_i(x)^2,$$

where $m \geq n$, $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $f_i(x)$ is the i -th component function of $F(x)$. From a current point, the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \|F(x_c) + J(x_c)(x_n - x_c)\| \quad \text{subject to} \quad \|x_n - x_c\|_2 \leq \Delta_c$$

to get the new point x_n as the solution to the following problem:

$$\min_{x \in \mathbb{R}^n} \|J^T(x)J(x) + J^T F(x)s\|_2,$$

where s is the trial step, and $\|s\|_2 \leq \Delta_c$,

then $x_n = x_c + s$.

The `RCI_Request` parameter informs about the task completion and may have the following values:

`RCI_Request`= 2 that indicates the requirement to calculate the Jacobian matrix and put the result into `fjac`.

`RCI_Request`= 1 that indicates the requirement to recalculate the function at vector `x` and put the result into `fvec`.

`RCI_Request`= 0 that indicates successful completion of the task

`RCI_Request`= -1 indicating that the algorithm has exceeded the maximal number of iterations.

$RCI\_Request = -2$ indicating that $\Delta_k < eps(1)$

$RCI\_Request = -3$ indicating that $\|F(x)\| < eps(2)$

$RCI\_Request = -4$ indicating that $\|A(x)_{ij}\| < eps(3)$

$RCI\_Request = -5$ indicating that $\|s\| < eps(4)$

$RCI\_Request = -6$ indicating that $\|F(x)\| - \|F(x) - A(x)s\| < eps(5)$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

<i>handle</i>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the function values at X , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	DOUBLE PRECISION. Array of size (m,n) . Contains the Jacobi matrix of the function.

Output Parameters

<i>fvec</i>	DOUBLE PRECISION. Array of size m . Contains the updated function values at x
<i>RCI_Request</i>	INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully. See Description for the other values of the parameter and their meaning.
<i>res</i>	INTEGER. Informs about the task completion. $res = TR\_SUCCESS$ means the routine completed the task normally.

dtrnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = dtrnlsp_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = dtrnlsp_get(&handle, &iter, &st_cr, &r1, &r2);
```

Description

The routine retrieves the current number of iterations, stop criterion, initial residual, and final residual.

The *st_cr* parameter contains the stop criterion:

st_cr = 1 indicates that the algorithm has exceeded the maximal number of iterations.

st_cr = 2 indicates that $\Delta_k < \text{eps}(1)$

st_cr = 3 indicates that $||F(x)|| < \text{eps}(2)$

st_cr = 4 indicates that $||A(x)_{ij}|| < \text{eps}(3)$

st_cr = 5 indicates that $||s|| < \text{eps}(4)$

st_cr = 6 indicates that $||F(x)|| - ||F(x) - A(x)s|| < \text{eps}(5)$,

where *A* is the Jacobi matrix, Δ_k is the trust region area, *F(x)* is the value of the functional, and *s* is the trial step.

Input Parameters

handle Data object of the `_TRNSP_HANDLE_t` type in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

iter INTEGER. Contains the current number of iterations.

st_cr INTEGER. Contains the stop criterion.

See Description for the parameter values and their meanings.

r1 DOUBLE PRECISION. Contains the initial residual, that is, the value of the functional $(||y - f(x)||)$ of the initial *x* set by the user.

r2 DOUBLE PRECISION. Contains the final residual, that is, the value of the functional $(||y - f(x)||)$ of the final *x* resulting from the algorithm operation.

res INTEGER. Informs about the task completion.

res = `TR_SUCCESS` means the routine completed the task normally.

dtrnlsp_delete

Removes the data object required by the TR solver.

Syntax

Fortran:

```
res = dtrnlsp_delete(handle)
```

C:

```
res = dtrnlsp_delete(&handle);
```

Description

The routine removes the data object needed for the RCI TR solver.

Input Parameters

<i>handle</i>	Data object of the <code>_TRNSP_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.

Output Parameters

<i>res</i>	<code>INTEGER</code> . Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> means the routine completed the task normally.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints can be described and solved in the same way as the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

Table 14-2 RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
<code>dtrnlspbc_init</code>	Initializes the solver.
<code>dtrnlspbc_solve</code>	Solves a nonlinear least squares problem on the basis of RCI using the Trust-Region algorithm.
<code>dtrnlspbc_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>dtrnlspbc_delete</code>	Removes data.

`dtrnlspbc_init`

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

Fortran:

```
res = dtrnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
```

C:

```
res = dtrnlspbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
```

Description

The routine initializes the solver. After initialization all invocations of the `dtrnlspbc_solve` routine should use the values of the handle returned by `dtrnlspbc_init`.

The *eps* array contains the stopping tests:

```
eps(1):  $\Delta_k < \text{eps}(1)$   
eps(2):  $\|F(x)\| < \text{eps}(2)$   
eps(3):  $\|A(x)_{ij}\| < \text{eps}(3)$   
eps(4):  $\|s\| < \text{eps}(4)$   
eps(5):  $\|F(x)\| - \|F(x) - A(x)s\| < \text{eps}(5)$ 
```

$eps(6)$: the trial step precision. If $eps(6) = 0$, then $eps(6) = 1.d-10$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

n	INTEGER. Length of x .
m	INTEGER. Length of $F(x)$.
x	DOUBLE PRECISION. Array of size n . Initial guess.
LW	DOUBLE PRECISION. Array of size n . Contains low bounds for x ($lw_i \leq x_i$).
UP	DOUBLE PRECISION. Array of size n . Contains upper bounds for x ($up_i \leq x_i$).
eps	DOUBLE PRECISION. Array of size 6; contains stopping tests. See the values in Description.
$iter1$	INTEGER. Specifies the maximum number of iterations.
$iter2$	INTEGER. Specifies the maximum number of iterations of trial-step calculation.
rs	DOUBLE PRECISION. Positive input variable used in determining the initial step bound. In most cases the factor should lie within the interval (0.1, 100.0). The generally recommended value is 100.

Output Parameters

$handle$	Data object of the <code>_TRNSPBC_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
res	INTEGER. Informs about the task completion. $res = TR\_SUCCESS$ indicates that the routine has completed the task normally. $res = TR\_INVALID\_OPTION$ indicates an error in the input parameters. $res = TR\_OUT\_OF\_MEMORY$ indicates a memory error.

dtrnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

Fortran:

```
res = dtrnlspbc_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = dtrnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
```

Description

The `dtrnlspbc_solve` routine, based on Reverse Communication Interface (RCI), uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} F(x)^T F(x) = \frac{1}{2} \sum_{i=1}^m f_i(x)^2, \text{ where } l_i \leq x_i \leq u_i \text{ } i = 1, \dots, n,$$

where $m \geq n$, $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $f_i(x)$ is the i -th component function of $F(x)$.

The `RCI_Request` parameter informs about the task completion and may have the following values:

`RCI_Request = 2` that indicates the requirement to calculate the Jacobian matrix and put the result into `fjac`.

`RCI_Request = 1` that indicates the requirement to recalculate the function at vector `x` and put the result into `fvec`.

`RCI_Request = 0` that indicates successful completion of the task

`RCI_Request = -1` indicating that the algorithm has exceeded the maximal number of iterations.

`RCI_Request = -2` indicating that $\Delta_k < \text{eps}(1)$

`RCI_Request = -3` indicating that $\|F(x)\| < \text{eps}(2)$

$RCI\_Request = -4$ indicating that $||A(x)_{ij}|| < eps(3)$

$RCI\_Request = -5$ indicating that $||s|| < eps(4)$

$RCI\_Request = -6$ indicating that $||F(x)|| - ||F(x) - A(x)s|| < eps(5)$,

where A is the Jacobi matrix, Δ_k is the trust region area, $F(x)$ is the value of the functional, s is the trial step.

Input Parameters

handle Data object of the `_TRNSPBC_HANDLE_t` type in C/C++ and `INTEGER*8` in FORTRAN.

fvec DOUBLE PRECISION. Array of size m . Contains the function values at X , where $fvec(i) = (y_i - f_i(x))$.

fjac DOUBLE PRECISION. Array of size m by n . Contains the Jacobi matrix of the function.

Output Parameters

fvec DOUBLE PRECISION. Array of size m . Contains the updated function values at X

RCI_Request INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully.
See Description for the other values of the parameter and their meaning.

res INTEGER. Informs about the task completion.
 $res = TR\_SUCCESS$ means the routine completed the task normally.

dtrnlspsc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = dtrnlspsc_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = dtrnlspsc_get(&handle, &iter, &st_cr, &r1, &r2);
```

Description

The routine retrieves the current number of iterations, stop criterion, initial residual, and final residual.

The *st_cr* parameter contains the stop criterion:

st_cr = 1 indicates that the algorithm has exceeded the maximal number of iterations.

st_cr = 2 indicates that $\Delta_k < \text{eps}(1)$

st_cr = 3 indicates that $\|F(x)\| < \text{eps}(2)$

st_cr = 4 indicates that $\|A(x)_{ij}\| < \text{eps}(3)$

st_cr = 5 indicates that $\|s\| < \text{eps}(4)$

st_cr = 6 indicates that $\|F(x)\| - \|F(x) - A(x)s\| < \text{eps}(5)$,

where *A* is the Jacobi matrix, Δ_k is the trust region area, *F*(*x*) is the value of the functional, *s* is the trial step.

Input Parameters

handle Data object of the `_TRNSPBC_HANDLE_t` type in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

<i>iter</i>	INTEGER. Contains the current number of iterations.
<i>st_cr</i>	INTEGER. Contains the stop criterion. See Description for the parameter values and their meanings.
<i>r1</i>	DOUBLE PRECISION. Contains the initial residual, that is, the value of the function $\ y - f(x)\ $ of the initial <i>x</i> set by the user.
<i>r2</i>	DOUBLE PRECISION. Contains the final residual, that is, the value of the function $\ y - f(x)\ $ of the final <i>x</i> resulting from the algorithm operation.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> means the routine completed the task normally.

dtrnlspbc_delete

Removes the data object required by the TR solver.

Syntax

Fortran:

```
res = dtrnlspbc_delete(handle)
```

C:

```
res = dtrnlspbc_delete(&handle);
```

Description

The routine removes the data object needed for the RCI TR solver.

Input Parameters

handle Data object of the `_TRNSPBC_HANDLE_t` type in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res INTEGER. Informs about the task completion.
res = `TR_SUCCESS` means the routine completed the task normally.

        f [4*i + 2] = (x [4*i + 1] - 2.0*x [4*i + 2])*(x [4*i + 1] - 2.0*x [4*i + 2]);
        f [4*i + 3] = 3.1622776601683793319988935444327*(x [4*i] - x [4*i + 3])*(x [4*i] - x [4*i
+ 3]);
    }
    return;
}
```

Jacobi Matrix Calculation Routines

This section describes routines that compute the Jacobi matrix using central differences. Jacobi matrix calculation is required to solve nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobi matrix have "Black-Box" interfaces, where users pass the objective function via parameters. Note that in this case the user's objective function must have fixed interface.

Table 14-3 Jacobi Matrix Calculation Routines

Routine Name	Operation
djacobi_init	Initializes the solver.
djacobi_solve	Computes the Jacobi matrix of the function on the basis of RCI using the central difference.
djacobi_delete	Removes data.
djacobi	Computes the Jacobi matrix of the fcn function using the central difference.

djacobi_init

Initializes the solver for Jacobian calculations.

Syntax

Fortran:

```
res = djacobi_init(handle, n, m, x, a, esp)
```

C:

```
res = djacobi_init(&handle, &n, &m, x, a, &eps);
```

Description

The routine initializes the solver.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Vector, at which the function is evaluated.
<i>eps</i>	DOUBLE PRECISION. Precision of the Jacobi matrix calculation.

Output Parameters

<i>handle</i>	Data object of the <code>_JACOBI_MATRIX_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>a</i>	DOUBLE PRECISION. Array of size (m, n) . Contains the Jacobi matrix of the function.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> indicates that the routine completed the task normally. <i>res</i> = <code>TR_INVALID_OPTION</code> indicates an error in the input parameters. <i>res</i> = <code>TR_OUT_OF_MEMORY</code> indicates a memory error.

djacobi_solve

Computes the Jacobi matrix of the function on the basis of RCI using the central difference.

Syntax

Fortran:

```
res = djacobi_solve(handle, f1, f2, RCI_Request)
```

C:

```
res = djacobi_solve(&handle, f1, f2, &RCI_Request);
```

Description

The `djacobi_solve` routine computes the Jacobi matrix of the function on the basis of RCI using the central difference.

Input Parameters

handle Data object of the `_JACOBI_MATRIX_HANDLE_t` type in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

f1 DOUBLE PRECISION. Array of size *m*. Contains the updated function values at $X + \epsilon$.

f2 DOUBLE PRECISION. Array of size *m*. Contains the updated function values at $X - \epsilon$.

RCI_Request INTEGER. Informs about the task completion. When equal to 0, the task is completed successfully.
RCI_Request = 1 indicates the user should calculate the Jacobian matrix and put the result into *f1*.
RCI_Request = 2 indicates the user should calculate the Jacobian matrix and put the result into *f2*.

res INTEGER. Informs about the task completion.
res = `TR_SUCCESS` indicates that the routine has completed the task normally.
res = `TR_INVALID_OPTION` indicates an error in the input parameters.

djacobi_delete

Removes the data object required by the Jacobian calculation.

Syntax

Fortran:

```
res = djacobi_delete(handle)
```

C:

```
res = djacobi_delete(&handle);
```

Description

The routine removes the data object needed for the Jacobi matrix RCI solver.

Input Parameters

<i>handle</i>	Data object of the <code>_JACOBIMATRIX_HANDLE_t</code> type in C/C++ and <code>INTEGER*8</code> in FORTRAN.

Output Parameters

<i>res</i>	<code>INTEGER</code> . Informs about the task completion. <i>res</i> = <code>TR_SUCCESS</code> means the routine completed the task normally.

djacobi

Computes the Jacobi matrix of the user's objective function using the cenral difference.

Syntax

Fortran:

```
res = djacobi(fcn, n, m, fjac, x, jac_eps)
```

C:

```
res = djacobi(fcn, &n, &m, fjac, x, &jac_eps);
```

Description

The routine computes the Jacobi matrix for function *fcn* using the central difference. This routine has "Black-Box" interface, where the user inputs the objective function via parameters. Note that in this case the user's objective function must have a fixed interface.

Input Parameters

<i>fcn</i>	User-supplied subroutine to evaluate the function that defines the least squares problem. Call <i>fcn</i> (<i>m</i> , <i>n</i> , <i>x</i> , <i>f</i>) with the following parameters: <i>m</i> - INTEGER. Input parameter. Length of <i>f</i> <i>n</i> - INTEGER. Input parameter. Length of <i>x</i> . <i>x</i> - DOUBLE PRECISION. Input parameter. Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter. <i>f</i> - DOUBLE PRECISION. Output parameter. Array of size <i>m</i> ; contains the function values at <i>x</i> . Declare <i>fcn</i> as EXTERNAL in the calling program.
<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	DOUBLE PRECISION. Array of size <i>n</i> . Vector at which the function is evaluated.
<i>eps</i>	DOUBLE PRECISION. Precision of the Jacobi matrix calculation.

Output Parameters

<i>a</i>	DOUBLE PRECISION. Array of size (<i>m</i> , <i>n</i>). Contains the Jacobi matrix of the function.
<i>res</i>	INTEGER. Informs about the task completion. <i>res</i> = TR_SUCCESS indicates that the routine has completed the task normally. <i>res</i> = TR_INVALID_OPTION indicates an error in the input parameters. <i>res</i> = TR_OUT_OF_MEMORY indicates a memory error.

Examples of djacobi_solve Usage

Example 14-5. djacobi_solve Usage in Fortran

return;  
}
```

Support Functions

Intel® MKL support functions are used to:

- retrieve information about the current Intel MKL version
- additionally control the number of threads
- handle errors
- test characters and character strings for equality
- measure user time for a process and elapsed CPU time
- set and measure CPU frequency
- free memory allocated by Intel MKL memory management software

Functions described below are subdivided according to their purpose into the following groups:

[Version Information Functions](#)

[Threading Control Functions](#)

[Error Handling Functions](#)

[Equality Test Functions](#)

[Timing Functions](#)

[Memory Functions](#)

Table 15-1 contains the list of support functions common for Intel MKL.

Table 15-1 Intel MKL Support Functions

Function Name	Operation
Version Information Functions	
<code>MKLGetVersion</code>	Returns information about the active library version.
<code>MKLGetVersionString</code>	Returns information about the library version string.
Threading Control Functions	
<code>mkl_set_num_threads</code>	Suggests the number of threads to use.
<code>mkl_domain_set_num_threads</code>	Suggests the number of threads for a particular function domain.
<code>mkl_set_dynamic</code>	Enables Intel MKL to dynamically change the number of threads.

Function Name	Operation
<code>mkl_get_max_threads</code>	Inquires about the number of threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Inquires about the number of threads targeted for parallelism in different domains.
<code>mkl_get_dynamic</code>	Returns the current value of the <code>MKL_DYNAMIC</code> variable.
Error Handling Functions	
<code>xerbla</code>	Handles error conditions for the BLAS, LAPACK, VML routines.
<code>pxerbla</code>	Handles error conditions for the ScaLAPACK routines.
Equality Test Functions	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
Timing Functions	
<code>second/dsecnd</code>	Returns user time for a process.
<code>getcpuclocks</code>	Returns full precision elapsed CPU clocks.
<code>getcpufrequency</code>	Returns CPU frequency value in GHz.
<code>setcpufrequency</code>	Sets CPU frequency value in GHz.
Memory Functions	
<code>MKL_FreeBuffers</code>	Frees memory buffers.
<code>MKL_MemStat</code>	Reports an amount of memory utilized by MKL Memory Manager.
<code>MKL_malloc</code>	Allocates the aligned memory buffer.
<code>MKL_free</code>	Frees the aligned memory buffer allocated by <code>MKL_malloc</code> .

Version Information Functions

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the `MKLGetString` function
- using the `MKLGetVersion` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

MKLGetVersion

Returns information about the active library C version.

Syntax

```
void MKLGetVersion( MKLVersion* pVersion );
```

Output Parameters

`pVersion` Pointer to the `MKLVersion` structure.

Description

The `MKLGetVersion` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the `pVersion` address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

<code>MajorVersion</code>	is the major number of the current library version.
<code>MinorVersion</code>	is the minor number of the current library version.
<code>BuildNumber</code>	is the update number of the current library version.
<code>ProductStatus</code>	is the status of the current library version. Possible variants could be "Beta", "Product".
<code>Build</code>	is the string that contains the build date and the internal build number.

Processor is the processor optimization that is targeted for the specific processor. It is not the definition of the processor installed in the system, rather the MKL library detection that is optimal for the processor installed in the system.

MKLGetVersion Usage

```
#include <stdio.h>
#include <stdlib.h>
#include "mkl_blas.h"
#include "mkl_types.h"

int main(void)
{
    MKLVersion Version;
    MKLGetVersion(&Version);

    printf("Major version:          %d\n", Version.MajorVersion);
    printf("Minor version:            %d\n", Version.MinorVersion);
    printf("Update number:              %d\n", Version.BuildNumber);
    printf("Product status:             %s\n", Version.ProductStatus);
    printf("Build:                      %s\n", Version.Build);
    printf("Processor optimization:    %s\n", Version.Processor);
    printf("=====\n");
    printf("\n");
    return 0;
}
```

Output:

Major Version	9
Minor Version	0

Build number	0
Product status	Product
Build	061909.09
Processor optimization	Intel® Xeon® Processor with Intel® 64 architecture

MKLGetVersionString

Gets the library version string.

Syntax

Fortran:

```
call MKLGetVersionString( buf )
```

C:

```
MKLGetVersionString( char* buf, int len );
```

Output Parameters

Name	Type	Description
<i>buf</i>	FORTTRAN: CHARACTER*198 C: char*	Source string
<i>len</i>	FORTTRAN: INTEGER C: int	Length of the source string

Description

This function returns a string that contains the library version information.
See example below:

Examples

Fortran:

```
program getversionstring

character*198 buf

call mklgetversionstring(buf)
write(*,'(a)') buf

end
```

C:

```
#include <stdio.h>
#include "mkl_blas.h"

int main(void)
{
    int len=198;
    char buf[198];
    MKLGetVersionString(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

Threading Control Functions

Intel® MKL provides optional threading control via service functions that take precedence over setting new environment variables with the same purpose (see *Intel® MKL User's Guide* for details).

These functions enable you to specify the number of threads for Intel MKL independently of the OpenMP* settings and prevailing over OpenMP* equivalents. Although Intel MKL may actually use the number of threads that differs from the one suggested, the controls will also enable you to instruct the library to try using the suggested number in the event of undetectable threading behavior in the application calling the library.

See the following examples of Fortran and C usage:

Fortran Usage

```
call mkl_set_num_threads( foo )
ret = mkl_domain_set_num_threads( num, MKL_BLAS )
call mkl_set_dynamic ( 1 )
num = mkl_get_max_threads()
num = mkl_domain_get_max_threads( MKL_BLAS );
ret = mkl_get_dynamic()
```

C Usage

```
#include "mkl.h" // Mandatory to make these definitions work!
mkl_set_num_threads(num); // Equivalent to omp_set_num_threads( int )
return_code = mkl_domain_set_num_threads( num, MKL_FFT );
mkl_set_dynamic( 1 );
num = mkl_get_max_threads();
num = mkl_domain_get_max_threads( MKL_FFT );
return_code = mkl_get_dynamic();
```

NOTE. Always remember to add `#include "mkl.h"` to use the C usage syntax.

mkl_set_num_threads

Suggests the number of threads to use.

Syntax

Fortran:

```
call mkl_set_num_threads( number )
```

C:

```
void mkl_set_num_threads( int number );
```

Input Parameters

Name	Type	Description
<i>number</i>	FORTTRAN: INTEGER C: int	Number of threads suggested by user

Description

This function allows the user to request independently of OpenMP* how many threads MKL should use. This is just a hint, and it is not guaranteed that this number of threads will be used. The user must enter a positive integer. This routine takes precedence over the `MKL_NUM_THREADS` environment variable .

See *Intel MKL User's Guide* for implementation details.

mkl_domain_set_num_threads

Suggests the number of threads for a particular function domain.

Syntax

Fortran:

```
call integer mkl_domain_set_num_threads( num, mask )
```

C:

```
int mkl_domain_set_num_threads( int num, int mask );
```

Input Parameters

Name	Type	Description
<i>num</i>	FORTRAN: INTEGER C: int	Number of threads suggested by user
<i>mask</i>	FORTRAN: INTEGER C: int	Name of the targeted domain

Description

This function allows the user to request different domains of Intel MKL to use different numbers of threads. The currently supported domains are:

- MKL_BLAS - BLAS domain
- MKL_FFT - FFT domain (excluding cluster FFT)
- MKL_VML - vector math library
- MKL_ALL - another way to do what `mkl_set_num_threads` does

This is just a hint, and it is not guaranteed that this number of threads will be used. The user must enter a valid domain and a positive integer for the number of threads. This routine has precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

See *Intel MKL User’s Guide* for implementation details.

Return Values

1 (true)	Indicates no error, execution is successful.
0 (false)	Indicates failure, possibly because the inputs were invalid.

mkl_set_dynamic

Enables Intel MKL to dynamically change the number of threads.

Syntax

Fortran:

```
call mkl_set_dynamic( boolean_var )
```

C:

```
void mkl_set_dynamic( int  boolean_var );
```

Input Parameters

Name	Type	Description
<i>boolean_var</i>	FORTRAN: INTEGER C: int	The parameter that determines whether dynamic adjustment of the number of threads is enabled or disabled.

Description

This function indicates whether or not Intel MKL can dynamically change the number of threads. The default for this is `true`, regardless of how the `OMP_DYNAMIC` variable is set. This will also hold precedent over the `OMP_DYNAMIC` variable.

A value of `false` does not guarantee that the user's requested number of threads will be used. But it means that MKL will attempt to use that value. This routine takes precedence over the environment variable `MKL_DYNAMIC`.

Note that if MKL is called from within a parallel region, MKL may not thread unless `MKL_DYNAMIC` is set to `false`, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

mkl_get_max_threads

Inquires about the number of threads targeted for parallelism.

Syntax

Fortran:

```
num = mkl_get_max_threads()
```

C:

```
int mkl_get_max_threads();
```

Description

This function allows the user to inquire independently of OpenMP* how many threads Intel MKL is targeting for parallelism. This is just a hint, and it is not guaranteed that this number of threads will be used.

See *Intel MKL User's Guide* for implementation details.

Return Values

The output is `INTEGER` equal to the number of threads.

`mkl_domain_get_max_threads`

Inquires about the number of threads targeted for parallelism in different domains.

Syntax

Fortran:

```
call integer mkl_domain_get_max_threads( mask )
```

C:

```
int mkl_domain_get_max_threads( int mask );
```

Input Parameters

Name	Type	Description
<i>mask</i>	FORTTRAN: <code>INTEGER</code> C: <code>int</code>	The name of the targeted domain

Description

This function allows the user of different domains of Intel MKL to inquire what number of threads is being used as a hint. The inquiry does not imply that this is the actual number of threads used. The number may vary depending on the value of the `MKL_DYNAMIC` variable and/or problem size, system resources, etc. But the function returns the value that MKL is targeting for the given domain.

The currently supported domains are:

- MKL_BLAS - BLAS domain
- MKL_FFT - FFT domain (excluding cluster FFT)
- MKL_VML - vector math library
- MKL_ALL - another way to do what `mkl_get_max_threads` does.

The user must enter a valid domain.

See *Intel MKL User's Guide* for implementation details.

Return Values

Returns the hint at the number of threads for the given domain.

mkl_get_dynamic

Returns current value of MKL_DYNAMIC variable.

Syntax

Fortran:

```
ret = mkl_get_dynamic()
```

C:

```
int mkl_get_dynamic();
```

Description

This function returns the current value of the `MKL_DYNAMIC` variable. This variable can be changed by manipulating the `MKL_DYNAMIC` environment variable before the MKL run is launched, or by calling `mkl_set_dynamic()`. Doing the latter has precedence over the former.

The function returns a value of 0 or 1. 1 indicates that `MKL_DYNAMIC` is true. 0 indicates that `MKL_DYNAMIC` is false. This variable indicates whether or not Intel MKL can dynamically change the number of threads. A value of `false` does not guarantee that the user's requested number of threads will be used. But it means that Intel MKL will attempt to use that value. This routine takes precedence over the environment variable `MKL_DYNAMIC`.

Note that if MKL is called from within a parallel region, MKL may not thread unless `MKL_DYNAMIC` is set to `false`, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

Return Values

1	Indicates MKL_DYNAMIC is true.
0	Indicates MKL_DYNAMIC is false.

Error Handling Functions

xerbla

Error handling routine called by BLAS, LAPACK, VML routines.

Syntax

```
call xerbla( sname, info )
```

Input Parameters

<i>sname</i>	CHARACTER*6. The name of the routine which called xerbla.
<i>info</i>	INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Description

The routine `xerbla` is an error handler for the BLAS, LAPACK, and VML routines. It is called by a BLAS, LAPACK, or VML routine if an input parameter has an invalid value.

A message is printed and execution stops.

Installers may consider modifying the `stop` statement to call system-specific exception-handling facilities.

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
call pxerbla(ictxt, sname, info)
```

Input Parameters

<i>ictxt</i>	(global) INTEGER The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) CHARACTER*6 The name of the routine which called <code>pxerbla</code> .
<i>info</i>	(global) INTEGER. The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called by a *ScaLAPACK* routine if an input parameter has an invalid value. A message is printed. Program execution is not terminated. For the *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and it is left to the user to determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *info* on return from a *ScaLAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Equality Test Functions

lsame

Tests two characters for equality regardless of the case.

Syntax

```
val = lsame( ca, cb )
```

Input Parameters

ca, cb CHARACTER*1. Specify the single characters to be compared.

Output Parameters

val LOGICAL. Result of the comparison.

Description

This logical function returns `.TRUE.` if *ca* is the same letter as *cb* regardless of the case.

lsamen

Tests two character strings for equality regardless of the case.

Syntax

```
val = lsamen( n, ca, cb )
```

Input Parameters

n INTEGER. The number of characters in *ca* and *cb* to be compared.

ca, cb CHARACTER*(*). Specify two character strings of length at least *n* to be compared. Only the first *n* characters of each string will be accessed.

Output Parameters

val LOGICAL. Result of the comparison.

Description

This logical function tests if the first *n* letters of the string *ca* are the same as the first *n* letters of *cb*, regardless of case. The function `lsamen` returns `.TRUE.` if *ca* and *cb* are equivalent except for the case and `.FALSE.` otherwise. `lsamen` also returns `.FALSE.` if `len(ca)` or `len(cb)` is less than *n*.

Timing Functions

second/dsecnd

Returns elapsed CPU time in seconds.

Syntax

```
val = second()
```

```
val = dsecnd()
```

Output Parameters

<i>val</i>	REAL for <code>second</code> DOUBLE PRECISION for <code>dsecnd</code> Elapsed CPU time in seconds.

Description

The `second/dsecnd` functions return the elapsed CPU time in seconds. These versions get the time from the elapsed CPU clocks divided by CPU frequency. The difference is that `dsecnd` returns the result with double precision.

The functions should be applied in pairs: the first time, before a routine to be measured, and the second time - after the measurement. The difference between the returned values is the time spent in the routine. The usage of `second` is discouraged for measuring short time intervals because the single precision format is not capable of holding sufficient timer precision.

getcpuclocks

Returns full precision elapsed CPU clocks.

Syntax

```
getcpuclocks( clocks )
```

Output Parameters

<i>clocks</i>	INTEGER*8. Elapsed CPU clocks.

Description

The `getcpuclocks` subroutine returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `getcpuclocks` subroutine is also applied in pairs like `second/dsecnd`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

getcpufrequency

Returns CPU frequency value in GHz.

Syntax

```
val = getcpufrequency()
```

Output Parameters

val DOUBLE PRECISION. CPU frequency value in GHz.

Description

The function `getcpufrequency` returns the CPU frequency in GHz. This value is used by `second/dsecnd` functions while converting CPU clocks into seconds.

Obtaining a frequency may take some time when `second/dsecnd/getcpufrequency` is called for the first time. To avoid it, call `setcpufrequency` before setting the exact CPU frequency if it is known in advance.

setcpufrequency

Sets CPU frequency value in GHz.

Syntax

```
setcpufrequency( freq )
```

Output Parameters

freq DOUBLE PRECISION. CPU frequency value in GHz.

Description

The `setcpufrequency` function sets the CPU frequency in GHz, used then by `second` / `dsecond` functions while converting CPU clocks into seconds. Setting the exact CPU frequency is useful to bypass obtaining a frequency by `getcpufrequency`.

Initially, CPU frequency value is unset. The CPU frequency value can be set only by `setcpufrequency` call, or during the first call of `getcpufrequency`, if `setcpufrequency` has not been called before. Calling `setcpufrequency` with a special parameter `freq = -1.0` forces the CPU frequency value be unset.

Note that the CPU frequency of your machine is not actually changed when the `setcpufrequency` subroutine is called.

Memory Functions

This section describes the Intel MKL memory support functions. See the *Intel® MKL User's Guide* for details of the Intel MKL memory management.

MKL_FreeBuffers

Frees memory buffers.

Syntax

```
void MKL_FreeBuffers(void)
```

Description

The `MKL_FreeBuffers` function frees the memory allocated by the Intel MKL Memory Manager. The Memory Manager allocates new buffers if no free buffers are currently available. Call `MKL_FreeBuffers()` to free all memory buffers and to avoid memory leaking on completion of work with the Intel MKL functions, that is, after the last call of an Intel MKL function from your application.

See *Intel® MKL User's Guide* for details.

MKL_FreeBuffers Usage with FFT Functions

```

-----
DFTI_DESCRIPTOR *hand1, *hand2;
void MKL_FreeBuffers(void);
. . . . .
/* Using MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . . . .
Status = DftiFreeDescriptor(&hand1);
/* Do not call MKL_FreeBuffers() here as the hand2 descriptor will be destroyed! */
. . . . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);
/* Here user finishes the MKL FFT usage */
/* Memory leak will be triggered by any memory control tool */
/* Use MKL_FreeBuffers() to avoid memory leaking */
MKL_FreeBuffers();
-----

```

If the memory space is sufficient, use `MKL_FreeBuffers` after the last call of the MKL functions. Otherwise, a drop in performance can occur due to reallocation of buffers for the subsequent MKL functions.

WARNING. For FFT calls, do not use `MKL_FreeBuffers` between `DftiCreateDescriptor(hand)` and `DftiFreeDescriptor(&hand)`.

MKL_MemStat

Reports amount of memory utilized by MKL Memory Manager.

Syntax

Fortran:

```
AllocatedBytes = MKL_MEMSTAT( AllocatedBuffers )
```

C:

```
AllocatedBytes = MKL_MemStat ( int* AllocatedBuffers );
```

Output Parameters

Name	Type	Description
<i>AllocatedBytes</i>	FORTTRAN: INTEGER*8 C: MKL_INT64	Amount of allocated bytes
<i>AllocatedBuffers</i>	FORTTRAN: INTEGER*4, C: int*	Number of allocated buffers

Description

The function returns the amount of the allocated memory in the *AllocatedBuffers* buffers. If there are no allocated buffers at the moment, the function returns 0. Call the `MKL_MemStat()` function to check the Intel MKL memory status.

Note that after calling `MKL_FreeBuffers()` there should not be any allocated buffers.

See [Example “MKL_malloc\(\), MKL_free\(\), MKL_MemStat\(\) Usage”](#).

MKL_malloc

Allocates the aligned memory buffer.

Syntax

Fortran:

```
ptr = MKL_MALLOC ( size, alignment )
```

C:

```
void* MKL_malloc ( size_t size , int alignment );
```

Input Parameters

Name	Type	Description
<i>size</i>	FORTTRAN: INTEGER C: size_t	Size of the buffer to be allocated
<i>alignment</i>	FORTTRAN: INTEGER C: int	Alignment of the allocated buffer

Output Parameters

Name	Type	Description
<i>ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the allocated buffer

Description

The function allocates a *size*-bytes buffer, aligned on the *alignment* boundary, and returns a pointer to this buffer.

The function returns `NULL` if *size* < 1. If alignment is not power of 2, the alignment 32 is used.

See [Example “MKL_malloc\(\), MKL_free\(\), MKL_MemStat\(\) Usage”](#).

MKL_free

Frees the aligned memory buffer allocated by MKL_malloc.

Syntax

Fortran:

```
CALL MKL_FREE ( ptr )
```

C:

```
void* MKL_free ( void* ptr );
```

Input Parameters

Name	Type	Description
<i>ptr</i>	FORTTRAN: POINTER C: void*	Pointer to the buffer to be freed

Description

The function frees the buffer pointed by *ptr* and allocated by `MKL_malloc()`.

See [Example “MKL_malloc\(\), MKL_free\(\), MKL_MemStat\(\) Usage”](#).

Examples of MKL_malloc(), MKL_free(), MKL_MemStat() Usage

Usage Example in Fortran

```
PROGRAM FOO

REAL*8      A,B,C
POINTER      (A_PTR,A(1)), (B_PTR,B(1)), (C_PTR,C(1))
INTEGER      N, I
REAL*8      ALPHA, BETA
INTEGER      ALLOCATED_BYTES
INTEGER      ALLOCATED_BUFFERS
INTEGER      MKL_MEMSTAT, MKL_MALLOC
EXTERNAL     MKL_MALLOC, MKL_FREE, MKL_MEMSTAT

ALPHA = 1.1; BETA = -1.2
N = 1000
A_PTR = MKL_MALLOC(8*N*N,128)
B_PTR = MKL_MALLOC(8*N*N,128)
C_PTR = MKL_MALLOC(8*N*N,128)
DO I=1,N*N
    A(1) = I
    B(1) = -I
    C(1) = 0.0
END DO

CALL DGEMM('N','N',N,N,N,ALPHA,A,N,B,N,BETA,C,N);

ALLOCATED_BYTES = MKL_MEMSTAT(ALLOCATED_BUFFERS)
```

```
PRINT *, 'DGEMM uses ', ALLOCATED_BYTES, ' bytes in ',  
$  ALLOCATED_BUFFERS, ' buffers '  
  
CALL MKL_FREEBUFFERS  
  
ALLOCATED_BYTES = MKL_MEMSTAT(ALLOCATED_BUFFERS)  
IF (ALLOCATED_BYTES > 0) THEN  
    PRINT *, 'MKL MEMORY LEAK!'  
    PRINT *, 'AFTER MKL_FREEBUFFERS there are ',  
$    ALLOCATED_BYTES, ' bytes in ',  
$    ALLOCATED_BUFFERS, ' buffers '  
END IF  
  
CALL MKL_FREE(A_PTR)  
CALL MKL_FREE(B_PTR)  
CALL MKL_FREE(C_PTR)  
  
STOP  
END
```

Usage Example in C

```
#include <stdio.h>

#include <mkl.h>

int main(void) {
    double *a, *b, *c;

    int n, i;

    double alpha, beta;

    MKL_INT64 AllocatedBytes;
    int N_AllocatedBuffers;

    alpha = 1.1; beta = -1.2;
    n = 1000;
    a = (double*)MKL_malloc(n*n*sizeof(double),128);
    b = (double*)MKL_malloc(n*n*sizeof(double),128);
    c = (double*)MKL_malloc(n*n*sizeof(double),128);
    for (i=0;i<(NN*NN);i++) {
        a[i] = (double)(i+1);
        b[i] = (double)(-i-1);
        c[i] = 0.0;
    }

    dgemm('N','N', &n, &n, &n, &alpha, a, &n, b, &n, &beta, c, &n);

    AllocatedBytes = MKL_MemStat(&N_AllocatedBuffers);
    printf('\nDGEMM uses %ld bytes in %d buffers', (long)AllocatedBytes, N_AllocatedBuffers);

    MKL_FreeBuffers();
}
```

```
AllocatedBytes = MKL_MemStat(&N_AllocatedBuffers);  
if (AllocatedBytes > 0) {  
    printf("\nMKL memory leak!");  
    printf("\nAfter MKL_FreeBuffers there are %ld bytes in %d buffers",  
        (long)AllocatedBytes, N_AllocatedBuffers);  
}  
  
MKL_free(a);  
MKL_free(b);  
MKL_free(c);  
  
return 0;  
}
```

BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the BLACS (Basic Linear Algebra Communication Subprograms) package that are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of m rows and n columns, with a leading dimension, lda , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (lda, n) . A pointer to the beginning of the (sub)array to be sent.

lda (input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by m , n , and lda , as above, but they have two additional parameters as well. These parameters are:

uplo (input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

diag (input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Figure 16-1 Trapezoidal Arrays Shapes

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max/min/sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the `max/min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex.

Table 16-1 BLACS Combines

Routine name	Results of operation
?gamx2d	Entries of result matrix will have the value of the greatest absolute value found in that position.
?gamn2d	Entries of result matrix will have the value of the smallest absolute value found in that position.
?gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (lda, n). Matrix to be compared with to produce the maximum.
<i>lda</i>	INTEGER. The leading dimension of the matrix A, that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.

<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i>, <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i>, <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i>, <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest
)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the minimum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.

<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i>, <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i>, <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i>, <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d(icontxt, scope, top, m, n, a, lda, rdest, cdest)
call sgsum2d(icontxt, scope, top, m, n, a, lda, rdest, cdest)
call dgsum2d(icontxt, scope, top, m, n, a, lda, rdest, cdest)
call cgsum2d(icontxt, scope, top, m, n, a, lda, rdest, cdest)
call zgsum2d(icontxt, scope, top, m, n, a, lda, rdest, cdest)
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

a TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM .EQ. 0) THEN
    SEND TO PROCESS 1
    RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
    SEND TO PROCESS 0
    RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

Table 16-2 BLACS Point To Point Communication

Routine name	Operation performed
?gesd2d ?trsd2d	Take the indicated matrix and send it to the destination process.
?gerv2d ?trrv2d	Receive a message from the process into the matrix.

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector x , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)
```

```
IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 1, 0)
    CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 0, 0)
    CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m,</i> <i>n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrsv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

uplo, diag, m, n, lda Describe the matrix to be sent. See [Matrix Shapes](#) for details.

rsrc INTEGER.
The process row coordinate of the source of the message.

csrc INTEGER.
The process column coordinate of the source of the message.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix A . This routine is globally-blocking, that is, return from the routine indicates that the message has been received into A .

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i` integer

s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

Table 16-3 BLACS Broadcast Routines

Routine name	Operation performed
?gebs2d	Start a broadcast along a scope.
?trbs2d	
?gebr2d	Receive and participate in a broadcast along a scope.
?trbr2d	

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.

<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d(icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m,</i> <i>n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix A .

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.

csrc INTEGER.
The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda,n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines

The support routines perform distinct tasks that can be used for:

- Initialization
- Destruction
- Information Purposes
- Miscellaneous Tasks.

Initialization Routines

This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

Table 16-4 BLACS Intialization Routines

Routine name	Operation performed
<i>blacs_pinfo</i>	Returns the number of processes available for use.
<i>blacs_setup</i>	Allocates virtual machine and spawns processes.
<i>blacs_get</i>	Gets values that BLACS use for internal defaults.
<i>blacs_set</i>	Sets values that BLACS use for internal defaults.

Routine name	Operation performed
<code>blacs_gridinit</code>	Assigns available processes into BLACS process grid.
<code>blacs_gridmap</code>	Maps available processes into BLACS process grid.

blacs_pinfo

Returns the number of processes available for use.

Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

Output Parameters

mypnum INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs INTEGER. The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, *nprows* * *npcols* ≤ *nprocs*. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to `BLACS_SETUP`, this routine returns the correct values for *mypnum* and *nprocs*.

blacs_setup

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

nprocs INTEGER. On the process spawned from the keyboard rather than from `pvmspawn`, this parameter indicates the number of processes to create when building the virtual machine.

Output Parameters

mypnum INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to `blacs_pinfo`. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

`blacs_setup` is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to `blacs_pinfo` informs you that the virtual machine has not been set up, and a call to `blacs_setup` then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

blacs_get

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icoctxt, what, val )
```

Input Parameters

<i>icoctxt</i>	INTEGER. On values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	INTEGER. Indicates what BLACS internal(s) should be returned in <i>val</i>. Present options are: • <i>what</i> = 0 : Handle indicating default system context • <i>what</i> = 1 : The BLACS message ID range • <i>what</i> = 2 : The BLACS debug level the library was compiled with • <i>what</i> = 10 : Handle indicating the system context used to define the BLACS context whose handle is <i>icoctxt</i> • <i>what</i> = 11 : Number of rings multiring topology is presently using • <i>what</i> = 12 : Number of branches general tree topology is presently using.

Output Parameters

<i>val</i>	INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into [blacs_gridinit](#) or [blacs_gridmap](#).

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have

strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter `icontxt` is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as `icontxt`. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for `TOP = 'M'` (multiring broadcast)
- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).

blacs_set

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( icontxt, what, val )
```

Input Parameters

<i>icontxt</i>	INTEGER. For values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	INTEGER. Indicates what BLACS internal(s) should be set. Present values are: • 1 = The BLACS message ID range • 11 = Number of rings for multiring topology to use • 12 = Number of branches for general tree topology to use.
<i>val</i>	INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.

Description

This routine sets the BLACS internal defaults depending on *what* values:

what = 1 Setting the BLACS message ID range.

If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to `blacs_gridinit` or `blacs_gridmap`. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter *icontxt* is ignored, and *val* is defined as:

VAL (input) INTEGER array of dimension (2)

VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use.

VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.

what = 11

Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so *icontxt* is used, and *val* is defined as:

VAL (input) INTEGER array of dimension (1)

VAL(1) : The number of rings for multiring topology to use.

what = 12

Set number of rings for TOP = 'T' (general tree broadcast/general tree gather). This quantity is tied to a context, so *icontxt* is used, and *val* is defined as:

VAL (input) INTEGER array of dimension (1)

VAL(1) : The number of branches for general tree topology to use.

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

call `blacs_gridinit( icontxt, order, nprow, npcol )`

Input Parameters

icontxt

INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call `blacs_get` to obtain a default system context.

order

CHARACTER*1. Indicates how to map processes to BLACS grid. Options are:

- 'R' : Use row-major natural ordering

- 'C' : Use column-major natural ordering
- ELSE : Use row-major natural ordering

nprow INTEGER. Indicates how many process rows the process grid should contain.

npcol INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple `nprow x npcol` process grid. This process grid uses the first `nprow * npcol` processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( ictxt, usermap, ldumap, nprow, npcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<i>usermap</i>	INTEGER. Array, dimension (<i>ldumap</i> , <i>npcol</i>), indicating the process-to-grid mapping.
<i>ldumap</i>	INTEGER. Leading dimension of the 2D array <i>usermap</i> . $ldumap \geq nprow$.
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.
<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

<i>ictxt</i>	INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner.

`usermap(i,j)` holds the process number of the process to be placed in $\{i, j\}$ of the process grid. On most distributed systems, this process number is a machine defined number between $0 \dots nprow-1$. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler.

`blacs_gridinit` simply performs a `gridmap` where the first $nprow * npcol$ processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

Table 16-5 BLACS Destruction Routines

Routine name	Operation performed
<code>blacs_freebuff</code>	Frees BLACS buffer.
<code>blacs_gridexit</code>	Frees a BLACS context.
<code>blacs_abort</code>	Aborts all processes.
<code>blacs_exit</code>	Frees all BLACS contexts and releases all allocated memory.

blacs_freebuff

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( ictxt, wait )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the BLACS context.
<i>wait</i>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The *wait* parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If *wait* = 0, the BLACS free any buffers that can be freed without waiting. If *wait* is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit

Frees a BLACS context.

Syntax

```
call blacs_gridexit( ictxt )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the BLACS context to be freed.

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort

Aborts all processes.

Syntax

```
call blacs_abort( icontxt, errornum )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the BLACS context to be aborted.
<i>errornum</i>	INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

continue INTEGER. Flag indicating whether message passing continues after the BLACS are done. If *continue* is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Informational Routines

This section describes BLACS routines that return information involving the process grid.

Table 16-6 BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

`blacs_gridinfo`

Returns information on the current grid.

Syntax

```
call blacs_gridinfo( ictxt, nprow, npcol, myprow, mypcol )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

Output Parameters

nprow INTEGER. Number of process rows in the current process grid.

npcol INTEGER. Number of process columns in the current process grid.

myproW INTEGER. Row coordinate of the calling process in the process grid.

mypcol INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

blacs_pnum

Returns the system process number of the process in the process grid.

Syntax

call blacs_pnum(*icontxt*, *prow*, *pcol*)

Input Parameters

icontxt INTEGER. Integer handle that indicates the context.

prow INTEGER. Row coordinate of the process the system process number of which is to be determined.

pcol INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {*PROW*, *PCOL*} in the process grid.

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( ictxt, pnum, prow, pcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
<i>pnum</i>	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a <code>tid</code> for PVM.

Output Parameters

<i>prow</i>	INTEGER. Row coordinates of the <i>pnum</i> process in the BLACS grid.
<i>pcol</i>	INTEGER. Column coordinates of the <i>pnum</i> process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Miscellaneous Routines

This section describes `blacs_barrier` routine.

Table 16-7 BLACS Informational Routines

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

blacs_barrier

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( icontxt, scope )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Parameter that indicates whether a process row (<i>scope</i> ='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example 16-1. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

```
PROGRAM HELLO
*
*  -- BLACS example code --
*
*  Written by Clint Whaley 7/26/94
*
*  Performs a simple check-in type hello world
*
*  ..
*
*  .. External Functions ..

*
*  EXTERNAL BLACS_PNUM
*
*  ..
*
*  .. Variable Declaration ..
*
*  INTEGER CONXTXT, IAM, NPROCS, NPROW, NPCOL, MYPROW, MYPCOL
*
*  INTEGER ICALLER, I, J, HISROW, HISCOL
*
*
*  Determine my process number and the number of processes in
*  machine
*
*
*  CALL BLACS_PINFO(IAM, NPROCS)
*
*
*  If in PVM, create virtual machine if it doesn't exist
*
*
*  IF (NPROCS .LT. 1) THEN
*    IF (IAM .EQ. 0) THEN
*      WRITE(*, 1000)
```

```

        READ(*, 2000) NPROCS
    END IF

    CALL BLACS_SETUP(IAM, NPROCS)
END IF

*
*   Set up process grid that is as close to square as possible
*
    NPROW = INT( SQRT( REAL(NPROCS) ) )
    NPCOL = NPROCS / NPROW

*
*   Get default system context, and define grid
*
    CALL BLACS_GET(0, 0, CONTXT)
    CALL BLACS_GRIDINIT(CONTXT, 'Row', NPROW, NPCOL)
    CALL BLACS_GRIDINFO(CONTXT, NPROW, NPCOL, MYPROW, MYPCOL)

*
*   If I'm not in grid, go to end of program
*
    IF ( (MYPROW.GE.NPROW) .OR. (MYPCOL.GE.NPCOL) ) GOTO 30

*
*   Get my process ID from my grid coordinates
*
    ICALLER = BLACS_PNUM(CONTXT, MYPROW, MYPCOL)

*
*   If I am process {0,0}, receive check-in messages from
*   all nodes
*
    IF ( (MYPROW.EQ.0) .AND. (MYPCOL.EQ.0) ) THEN

```

```

Example 16-3. BLACS Usage. PARALLEL DOT PRODUCT

This routine does a bone-headed parallel double precision dot product of two vectors. Arguments are input on process {0,0}, and output everywhere else.

```

      DOUBLE PRECISION FUNCTION PDDOT( CONTEXT, N, X, Y )
*
*   -- BLACS example code --
*   Written by Clint Whaley 7/26/94
*   ..
*   .. Scalar Arguments ..
      INTEGER CONTEXT, N
*   ..
*   .. Array Arguments ..
      DOUBLE PRECISION X(*), Y(*)
*   ..
*
* Purpose
* =====
* PDDOT is a restricted parallel version of the BLAS routine
* DDOT.  It assumes that the increment on both vectors is one,
* and that process {0,0} starts out owning the vectors and
*
* has N.  It returns the dot product of the two N-length vectors
* X and Y, that is, PDDOT = X' Y.
*
* Arguments
* =====
*
* CONTEXT      (input) INTEGER
*
*              This integer is used by the BLACS to indicate a context.

```

```

*           A context is a universe where messages exist and do not
*           interact with other context's messages. The context
*
*           includes the definition of a grid, and each process's
*
*           coordinates in it.
*
*
* N         (input/output) INTEGER
*           The length of the vectors X and Y. Input
*           for {0,0}, output for everyone else.
*
*
* X         (input/output) DOUBLE PRECISION array of dimension (N)
*           The vector X of  $PDDOT = X' Y$ . Input for {0,0},
*           output for everyone else.
*
*
* Y         (input/output) DOUBLE PRECISION array of dimension (N)
*           The vector Y of  $PDDOT = X' Y$ . Input for {0,0},
*           output for everyone else.

Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an $m \times n$ matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in section [Sparse Linear Systems](#) that follows.

If the coefficients in matrix A and right-hand sides in vector b are not defined exactly but rather belong to known intervals, the system is called an *interval linear system*. Some basic definitions and concepts used in solving interval linear systems are described in section [Interval Linear Systems](#).

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix A . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently for the right applications, iterative solvers can be very efficient.

Direct Solvers, on the other hand, often factor the matrix A into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array A .

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix A is denoted by $a(i, j)$. For example, a 3 by 4 matrix A , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i, j) = a(j, i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i, j) = \text{conj}(a(j, i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements $a(i, j)$ and $a(j, i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product $x^T A x$ is greater than zero for all non-zero vectors x . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A , the result of the matrix product PA is identical to A except for interchanging the rows of A . For a square matrix, it can be shown that if PA is a permutation of the rows of A , then AP^T is the same permutation of the columns of A . Additionally, it can be shown that the inverse of P is P^T .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i -th row of a matrix to the j -th row, then the i -th element of the permutation vector is j .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U , such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUx &= b \\ \Rightarrow (Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A , that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H . Consequently, a solver can increase its efficiency by only storing L , and one-half of A , and not computing U . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L , D , and half of A and we need not compute U . However, the backward solve phases must be amended to solving $L^T x = D^{-1} y$ rather than $L^T x = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is the symmetric positive definite sparse matrix defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & 1 & * & * & * \\ 2 & 2 & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & \frac{5}{8} & * & * \\ 3 & * & * & * & 16 \end{bmatrix} b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A . The Cholesky factorization of A is: $A = LL^T$, where L is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ \frac{1}{2} & \frac{1}{2} & * & * & * \\ 2 & -2 & 2 & * & * \\ \frac{1}{4} & \frac{1}{-4} & \frac{1}{-2} & \frac{1}{2} & * \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L . By doing this, the solver would only need to compute the non-zero entries in L . Toward this end, consider permuting the rows and columns of A . As described in [Matrix Fundamentals](#) section, the permutations of the rows of A can be represented as a permutation matrix, P . The result of permuting the rows is the product of P and A . Suppose, in the above example, we swap the first and fifth row of A , then swap the first and fifth columns of A , and call the resulting matrix B . Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A , we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A . Consequently, the storage and computation time needed to factor B is much smaller than to factor A . Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A , which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^TP)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an LU factorization for B , we can solve the original system of equations by a three step process:

- 1.** Solve $Ly = Pb$.
- 2.** Solve $Uz = y$.
- 3.** Set $x = P^Tz$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives:

$$Y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12}.$$

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since we are using a Cholesky factorization, $L^T z = y$.

$$\begin{bmatrix}
 4 & * & * & * & \frac{3}{4} \\
 * & \frac{1}{\sqrt{2}} & * & * & \frac{3}{\sqrt{2}} \\
 * & * & 2(\sqrt{3}) & * & \sqrt{3} \\
 * & * & * & \frac{\sqrt{10}}{4} & \frac{3}{\sqrt{10}} \\
 \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4}
 \end{bmatrix} * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12} \end{bmatrix}$$

This gives

$$z = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}.$$

The third and final step is to set $x = P^T z$. This gives

$$X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}.$$

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

The storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column that contains the <i>I</i> -th element in the <i>values</i> array.
<i>rowIndex</i>	Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *I*-th row is equal to the difference of *rowIndex*(*I*) and *rowIndex*(*I*+1).

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

NOTE. The Intel MKL sparse storage scheme for the direct sparse solvers uses the Fortran programming language convention of starting array indices at 1.

Consider the symmetric matrix *A*:

$$A = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{bmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix *A* are as follows:

Table A-1 Storage Arrays for a Symmetric Matrix

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)	
<i>columns</i>	=	(1	2	4	2	3	4	5	4	5)	
<i>rowIndex</i>	=	(1	4	5	8	9	10)				

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix *B*:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

Table A-2 Storage Arrays for a Non-Symmetric Matrix

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if *a*(*j*,*i*) is not zero if and only if *a*(*j*,*i*) is not zero. From the point of view of the solver software, a "non-zero" element of a matrix

is any element stored in the *values* array, even if its value is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{bmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Table A-3 Storage Arrays for a Symmetrically Structured Matrix

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
<i>columns</i>	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)
<i>rowIndex</i>	=	(1	4	7	10	13	16)									

Storage Format Restrictions

- The storage format for the sparse solver must conform to two important restrictions:
- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
 - no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

This section describes in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

CSR Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains row indices, such that <i>pointerE(j)-pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE. Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix *B*

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

can be represented in the CSR format as:

Table A-4 Storage Arrays for a Matrix in CSR Format

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
pointerB	=	(1	4	6	9	12)								
pointerE	=	(4	6	9	12	14)								
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
pointerB	=	(0	3	5	8	11)								
pointerE	=	(3	5	8	11	13)								

This storage format is used in the NIST Sparse BLAS library [[Rem05](#)].

Note that the storage format accepted for the direct sparse solvers and described above (see [Storage Formats for the Direct Sparse Solvers](#)) is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix *B* can be represented in this format (referred to as the 3-array variation of the CSR format) as:

Table A-5 Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row *J* goes just after the set of non-zero elements in the row *J-1*.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

Comparing the array *rowIndex* from the Table A-2 with the arrays *pointerB* and *pointerE* from the Table A-4 it is easy to see that

pointerB(I) = rowIndex(I) for I=1, ..5;

pointerE(I) = rowIndex(I+1) for I=1, ..5.

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
Subroutine name_routine(... , values, columns, pointerB, pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
call name_routine(... , values, columns, rowIndex, rowindex(2), ...).
```

CSC Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element <i>I</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains column indices, such that <i>pointerE(j)-pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE. Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

The above matrix *B* can be represented in the CSC format as:

Table A-6 Storage Arrays for a Matrix in CSC Format

one-based indexing														
values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(1	2	4	1	2	5	3	4	1	3	4	2	5)
pointerB	=	(1	4	7	9	12)								
pointerE	=	(4	7	9	12	14)								
zero-based indexing

pointerE	=	(3	6	8	11	13)								

Coordinate Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> in any order.
<i>rows</i>	Element <i>I</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array.
<i>columns</i>	Element <i>I</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>I</i> -th value in the <i>values</i> array .

NOTE. Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *c*

$$c = \begin{bmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{bmatrix}$$

can be represented in the coordinate format as follows:

Table A-7 Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing														
<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
<i>columns</i>	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
<i>columns</i>	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Diagonal Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

values

A real or complex two-dimensional array is dimensioned as *lval* by *ndiag*. Each column of it contains the non-zero elements of certain diagonal of *A*. The key point of the storage is that each element in *values* retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of *distance(I)* is the number of elements to be padded for diagonal *I*.

distance

An integer array with dimension *ndiag*. Element *I* of the array *distance* is the distance between *I*-diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$\begin{aligned}
 &\text{distance} = (-3 \quad -1 \quad 0 \quad 1 \quad 2) \\
 &\text{values} = \begin{bmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{bmatrix}
 \end{aligned}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Skyline Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

<i>values</i>	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
<i>pointers</i>	An integer array with dimension $(m+1)$, where m is the number of rows for lower triangle (columns for the upper triangle). $pointers(I) - pointers(1)+1$ gives the index of element in <i>values</i> that is first non-zero element in row (column) I . The value of $pointers(m+1)$ is set to $nz+pointers(1)$, where nnz is the number of elements in the array <i>values</i> .

For example, the low triangle of the matrix C given above can be stored as follows:

```
values = ( 1  -2  5  4  -4  0  2  7  8  0  0  -5 )
```

```
pointers = ( 1  2  4  5  9  13 )
```

and the upper triangle of this matrix C can be stored as follows:

```
values = ( 1  -1  5  -3  0  4  6  7  4  0  -5 )
```

```
pointers = ( 1  2  4  7  9  12 )
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format does not support general matrices.

BSR Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of

	them is equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.
<i>pointerE</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row <i>j</i> of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE. Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix *D*

$$D = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 2 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix *D* can be represented as a 3x3 block matrix *E* with the following structure:

$$E = \begin{bmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 1 \end{bmatrix}, P = \begin{bmatrix} 4 & 3 \\ 0 & 0 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

`values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)`

`columns = (1 2 2 2 3)`

`pointerB = (1 3 4)`

`pointerE = (3 4 6)`

zero-based indexing

`values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)`

`columns = (0 1 1 1 2)`

`pointerB = (0 2 3)`

`pointerE = (2 3 5)`

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Intel MKL supports the variation of the BSR format that is specified by three arrays: `values`, `columns`, and `rowIndex`. The following table describes these arrays.

<code>values</code>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<code>columns</code>	Element i of the integer array <code>columns</code> is the number of the column in the block matrix that contains the i -th non-zero block.
<code>rowIndex</code>	Element j of this integer array gives the index of the element in the <code>columns</code> array that is first non-zero block in a row j of the block matrix.

The length of the `values` array is equal to the number of all elements in the non-zero blocks, the length of the `columns` array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *I*-th row is equal to the difference of *rowIndex*(*I*) and *rowIndex*(*I*+1).

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zeros blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

values = (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)

columns = (1 2 2 2 3)

rowIndex = (1 3 4 6)

zero-based indexing

values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)

columns = (0 1 1 1 2)

rowIndex = (0 2 3 5)

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix *F* can be represented as a 3x3 block matrix *G* with the following structure:

$$G = \begin{bmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, M' = \begin{bmatrix} 6 & 8 \\ 7 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 2 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only upper triangular) as follows:

one-based indexing

`values = (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)`

`columns = (1 2 2 3)`

`rowIndex = (1 3 4 5)`

zero-based indexing

`values = (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)`

`columns = (0 1 1 2)`

`rowIndex = (0 2 3 4)`

Interval Linear Systems

Intervals

An interval is a compact connected subset of the real axis $\mathbf{R}$. It is thus completely defined by two numbers, namely, its *lower endpoint* and *upper endpoint* (sometimes called *left endpoint* and *right endpoint* respectively), so that $[a, b]$ denotes the interval $\{x \in \mathbf{R} \mid a \leq x \leq b\}$. The set of all real intervals is denoted by $\mathbf{IR}$. In mathematical notation, taking the lower and upper endpoints of an interval is usually denoted by

$\inf[a, b] = a, \sup[a, b] = b.$

In the discussion below, intervals and interval objects are denoted by boldface letters, while underscores and overscores designate the lower and upper endpoints of the interval $\mathbf{x} = [\underline{\mathbf{x}}, \overline{\mathbf{x}}]$

Every interval is uniquely determined by its *midpoint*,

$$\text{mid } \mathbf{a} = \frac{1}{2} (\bar{\mathbf{a}} + \underline{\mathbf{a}}),$$

and radius,

$$\text{rad } \mathbf{a} = \frac{1}{2} (\bar{\mathbf{a}} - \underline{\mathbf{a}})$$

the latter being equivalent to the width $\text{wid } \mathbf{a} = \bar{\mathbf{a}} - \underline{\mathbf{a}}$. Intervals of the form $[\mathbf{a}, \mathbf{a}]$ that have equal lower and upper endpoints, that is, intervals of zero width, are called *degenerate* or *point* or *thin*, and they coincide with usual real numbers so that it can be implied $\mathbf{R} \subset \mathbf{IR}$. On the contrary, the intervals with nonzero width are called *thick* intervals.

Since intervals are sets, set-theoretical relations and operations between them are applicable, for example, inclusion, intersection, and so on. In particular, a point $t \in \mathbf{R}$ is a member of the interval $\mathbf{a}$ (written as $t \in \mathbf{a}$) if $\underline{\mathbf{a}} \leq t \leq \bar{\mathbf{a}}$. Also, the inclusion is defined as $\mathbf{a} \subseteq \mathbf{b}$ if and only if $\underline{\mathbf{a}} \geq \underline{\mathbf{b}}$ and $\bar{\mathbf{a}} \leq \bar{\mathbf{b}}$.

Intervals and interval objects (vectors, matrices, etc.) are a convenient tool to represent the so-called *bounded* uncertainty and ambiguity, when only the lower and upper bounds of the possible variation of some value are known. In this sense, intervals provide an alternative to probabilistic and fuzzy approaches for describing quantitative uncertainty.

Arithmetic operations, such as addition, subtraction, multiplication and division, can be extended to intervals according to the fundamental principle

$$\mathbf{a} * \mathbf{b} = \{a * b \mid a \in \mathbf{a}, b \in \mathbf{b}\}, \quad * \in \{+, -, \cdot, /\}, \quad (1)$$

which makes it possible to define the so-called *classical interval arithmetic*. Note that the empty interval $[\emptyset]$ is often incorporated into the computer interval arithmetic structures.

Interval vectors and matrices

An interval vector is an ordered tuple of intervals placed vertically(column vector) or horizontally(row vector). So, if $a_1, a_2, \dots, a_n$ are intervals, then

$$a = \begin{pmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{pmatrix} \text{ is a column vector,}$$

and

$a_1, a_2, \dots, a_n$ is a row vector.

The set of all interval n -vectors is denoted later in the text by $\mathbf{IR}^n$.

The interval vectors can be associated with their geometric images, namely rectangular boxes of the space $\mathbb{R}^n$, whose sides are parallel to the coordinate axes. For this reason, interval vectors are often called *boxes* for brevity.

An *interval matrix* is a rectangular table composed of the intervals:

$$\mathbf{A} := \begin{pmatrix} \mathbf{a}_1 \\ \mathbf{a}_2 \\ \vdots \\ \mathbf{a}_m \end{pmatrix} = \begin{pmatrix} \mathbf{a}_{11} & \mathbf{a}_{12} & \dots & \mathbf{a}_{1n} \\ \mathbf{a}_{21} & \mathbf{a}_{22} & \dots & \mathbf{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{a}_{m1} & \mathbf{a}_{m2} & \dots & \mathbf{a}_{mn} \end{pmatrix},$$

or $\mathbf{A} = (\mathbf{a}_{ij})$. Interval vectors can be identified with interval matrices either of the size $n \times 1$ (column vectors) or $1 \times n$ (row vectors). The set of all interval $m \times n$ -matrices is denoted by $\mathbf{IR}^{m \times n}$. Arithmetic operations between interval vectors and matrices can be introduced on the basis of the relation that generalizes (1) (see [Alefeld83], [Neumaier90]).

An interval square matrix $\mathbf{A} \in \mathbf{IR}^{n \times n}$ is referred to as *regular* (nonsingular) if and only if all the point matrices $\mathbf{A} \in \mathbf{A}$ are regular (nonsingular), that is, have nonzero determinants.

Otherwise, the interval matrix $\mathbf{A} \in \mathbf{IR}^{n \times n}$ is called *singular*, which means that it contains at least one singular point matrix.

Generally, recognition of whether an interval matrix is regular or singular is an NP-hard problem, which implies that there may be no relatively simple (polynomially complex) algorithms that completely solve the problem in a reasonable time.

For practical needs, it is important to have a set of workable sufficient criteria for testing regularity of a wide range of interval matrices. Intel MKL provides routines that implement Ris-Beeck spectral criterion, Rump singular value criterion, as well as Rohn-Rex singular value criterion for testing regularity/singularity of interval matrices.

Sometimes, a related property (called *strong regularity*) needs to be checked for interval matrices. Strong regularity requires that the product of the interval matrix by its midpoint inverse is regular. The routine `?gerbr` enables to check the strong regularity judging by the value of its output parameter `sr`.

Interval Linear Systems

Solving systems of linear algebraic equations of the form

$$\begin{cases} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1, \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2, \\ \vdots \quad \quad \quad \ddots \quad \quad \quad \vdots \\ a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_m, \end{cases} \quad (2)$$

or, concisely,

$$Ax = b$$

with an $m \times n$ matrix A and a right-hand side m -vector b , is one of the key problems in science and engineering. If a_{ij} and b_i are not defined exactly but rather belong to known intervals $\mathbf{a}_{ij}$ and $\mathbf{b}_i$ respectively, the system is called an *interval linear system* and can be written as

$$\begin{cases} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1, \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2, \\ \vdots \quad \quad \quad \ddots \quad \quad \quad \vdots \\ a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_m, \end{cases} \quad (3)$$

with intervals $\mathbf{a}_{ij}$ and $\mathbf{b}_i$, or in a short form as

$$\mathbf{A}x = \mathbf{b} \quad (4)$$

with an interval matrix $\mathbf{A} = (\mathbf{a}_{ij})$ and interval right-hand side vector $\mathbf{b} = (\mathbf{b}_i)$. An interval linear system (3)–(4) is considered as a set of point linear systems of the same form $Ax = b$ with the parameters a_{ij} and b_i such that $a_{ij} \in \mathbf{a}_{ij}$ and $b_i \in \mathbf{b}_i$.

When a_{ij} and b_i are changing within intervals $\mathbf{a}_{ij}$ and $\mathbf{b}_i$, the solutions to the corresponding point systems $Ax = b$ with $A = (a_{ij})$ and $b = (b_i)$ form a set in the space $\mathbb{R}^n$, namely

$$\Xi(\mathbf{A}, \mathbf{b}) := \{x \in \mathbb{R}^n \mid (\exists A \in \mathbf{A}) (\exists b \in \mathbf{b}) (Ax = b)\}. \quad (5)$$

The set (5), made up of solutions to all the point systems $Ax = b$ with $A \in \mathbf{A}$ and $b \in \mathbf{b}$, is called a *solution set* to the interval linear system (3)–(4). Usually, the solution set is a solid polyhedron in $\mathbb{R}^n$ for independent a_{ij} and b_i , $1 \leq i, j \leq n$, sometimes star-shaped as in the figure below.

NOTE. The above described set $\Xi(\mathbf{A}, \mathbf{b})$ is often called a *untied solution set*, since there exist a variety of other solution sets to interval systems of equations (see [[Shary02](#)]).

An exact description of the solution set is practically impossible for dimensions n larger than several tens, since its complexity grows exponentially with n . On the other hand, such an exact description is not really necessary in most cases. Usually, one needs to compute some *estimates*, in a prescribed sense, of the solution set. The most popular in practice is the following problem of *outer* (by supersets) interval estimation:

For an interval system of linear equations $\mathbf{Ax} = \mathbf{b}$ (6)

find an interval enclosure of the solution set $\Xi(\mathbf{A}, \mathbf{b})$.

Frequently, a component-wise form of the problem (6) is considered:

For an interval system of linear equations $\mathbf{Ax} = \mathbf{b}$ (7)

find estimates for $\min\{x_v | x \in \Xi(\mathbf{A}, \mathbf{b})\}$ from below,

for $\max\{x_v | x \in \Xi(\mathbf{A}, \mathbf{b})\}$ from above, $v = 1, 2, \dots, n$.

In particular, Intel MKL [?gepps](#) routines operate with this type of the problem statement.

The problem (6)–(7) is one of the historically first and most popular in modern interval analysis. You can find an extensive bibliography on this problem, for example, in [\[Alefeld83\]](#), [\[Kearfott96\]](#), [\[Neumaier90\]](#).

Thus, solving an interval linear system is understood here as computing an outer interval estimate of the solution set to an interval linear system (3)–(4). The matrix $\mathbf{A}$ of the system is usually assumed to be square nonsingular.

Unlike classical computational linear algebra, solving interval linear systems proves to be very computationally hard in general. Computing the optimal (smallest) interval enclosures of the solution in (6), or, equivalently, computing exact estimates of the solution set in (7), is an NP-hard problem (see [\[Kreinovich97\]](#)), if there are no restrictions on the widths of the intervals in the system and/or the structure of nonzero elements in the matrix $\mathbf{A}$. Moreover, the problem remains NP-hard even if we weaken the requirements on the solution and compute estimates of the solution sets that must be precise to within a predetermined absolute or relative accuracy.

From the practical standpoint, NP-hardness means that with a high probability a general problem cannot be solved in polynomial time with respect to problem size.

For this reason, numerical algorithms employed in Intel MKL for solving interval linear systems are divided into two classes depending on whether or not they provide a guaranteed accuracy of the result. “Fast” algorithms work fast and compute an enclosure of the solution set in a reasonable time, but without any accuracy assumptions. “Optimal”, or “sharp” algorithms may take a lot of time to complete execution, but the results they obtain are less crude and may satisfy some accuracy requirements.

Intel MKL includes interval solver routines that implement algorithms of both types. For example, fast methods, such as interval Gauss method, interval Householder method, Hansen-Bliek-Rohn method, and Krawczyk iteration, are implemented in routines `?gegas`, `?gehss`, `?gehbs`, and `?gekws`, respectively. Parameter partitioning method (PPS-method) implemented in `?gepps` routine is an example of a sharp method. The routine `?trtrs` is subsumed under both categories due to a very special matrix structure.

Preconditioning

Preconditioning of interval linear system (4) is multiplying both the matrix $\mathbf{A}$ and the right-hand side vector $\mathbf{b}$ by a point matrix, with the intension to improve the properties of the system. So the system $\mathbf{Ax} = \mathbf{b}$ is substituted by the following system

$$(\mathbf{CA})\mathbf{x} = \mathbf{Cb}$$

where $\mathbf{C}$ is some square point matrix. Preconditioning is widely used in classical computational linear algebra, and many interval solver algorithms (for example, interval Gauss method, interval Gauss-Seidel method and some others) also require a suitable preconditioning prior to their use.

One of the widely used preconditioning methods for the interval linear systems is preconditioning done by the inverse of the midpoint matrix, often called *midpoint-inverse preconditioning*. In Intel MKL, the midpoint inverse preconditioning is implemented in the routine `?gemip`.

Inverting interval matrices

Given an interval square matrix $\mathbf{A}$, an enclosure for the set of all inverse point matrices in $\mathbf{A}$ is called the *inverse interval matrix* $\mathbf{A}^{-1}$, that is,

$$\mathbf{A}^{-1} \supseteq \{A^{-1} | A \in \mathbf{A}\}.$$

In classical linear algebra, the solution to a system of linear algebraic equations $\mathbf{Ax} = \mathbf{b}$ with square nonsingular matrix $\mathbf{A}$ can be expressed as the product of the inverse $\mathbf{A}^{-1}$ by the right-hand side vector, or $\mathbf{x} = \mathbf{A}^{-1}\mathbf{b}$.

In interval analysis, the similar product $\mathbf{A}^{-1}\mathbf{b}$ also produces an enclosure for the solution set $\Xi\mathbf{A}, \mathbf{b}$ of the interval linear system $\mathbf{Ax} = \mathbf{b}$. However, this method usually causes substantial overestimation and is not recommended. Using specialized procedures for outer estimation of the solution sets is preferable.

Nevertheless, computing tight enclosures for inverse interval matrices is essential in sensitivity-like analysis of equation systems and the like.

Computing the inverse interval matrix may be carried out as finding an enclosure for the solution set of the following interval matrix equation

$\mathbf{A}\mathbf{Y} = \mathbf{I}$, where $\mathbf{I}$ is the identity matrix,

by applying n times (for every column of the matrix $\mathbf{Y}$) any method to solve the interval linear systems.

Note also that direct iterative procedures for finding the inverse interval matrix exist, such as Schulz method (see [[Herzberger94](#)]), which is included into Intel MKL as `?geszi` routine.

Routine and Function Arguments

B

The major arguments in the BLAS routines are vector and matrix, whereas VML functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length n and increment $incx$ is passed in a one-dimensional array x whose values are defined as

$x(1), x(1+|incx|), \dots, x(1+(n-1)*|incx|)$

If $incx$ is positive, then the elements in array x are stored in increasing order. If $incx$ is negative, the elements in array x are stored in decreasing order with the first element defined as $x(1+(n-1)*|incx|)$. If $incx$ is zero, then all elements of the vector have the same value, $x(1)$. The dimension of the one-dimensional array that stores the vector must always be at least

$idimx = 1 + (n-1)*|incx|$

Example B-1 One-dimensional Real Array

Let $x(1:7)$ be the one-dimensional real array

$x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0)$.

If $incx = 2$ and $n = 3$, then the vector argument with elements in order from first to last is $(1.0, 5.0, 9.0)$.

If $incx = -2$ and $n = 4$, then the vector elements in order from first to last is $(13.0, 9.0, 5.0, 1.0)$.

If $incx = 0$ and $n = 4$, then the vector elements in order from first to last is $(1.0, 1.0, 1.0, 1.0)$.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified. In Fortran, storing the m -by- n matrix is based on column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is m , and the increment between elements on the same diagonal is $m + 1$.

Example B-2 Two-dimensional Real Matrix

Let a be the real 5 x 4 matrix declared as `REAL A (5,4)`.

To scale the third column of a by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
callsscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
callsscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of A by 2.0, use the statement:

```
callsscal (5, 2.0, a(1,1), 6)
```

NOTE. The default vector argument is assumed to be 1.

Vector Arguments in VML

Vector arguments of VML mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as $a[0]$, $a[1]$, ..., $a[n-1]$ (for C- interface).

To accommodate for arrays with other increments, or more complicated indexing, VML contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

```
a[m0], a[m1], ..., a[mn-1]
```

and need to be regrouped into an array y as

```
y[k0], y[k1], ..., y[kn-1],
```

VML pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = incy * j, mj = inca * j, j = 0, ..., n-1
```

Constraint: $incy > 0$ and $inca > 0$.

For example, setting $incy = 1$ specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

$kj = iy[j], mj = ia[j], j = 0, \dots, n-1,$

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y , respectively.

Mask Vector Indexing

Indices kj, mj are such that:

$my[kj] \neq 0, ma[mj] \neq 0, j = 0, \dots, n-1,$

where ma and my are arrays that contain mask vectors for the input and output arrays a and y , respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in either one- or two-dimensional arrays, using the following storage schemes:

- conventional full storage (in a two-dimensional array)
- packed storage for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- band storage for band matrices (in a two-dimensional array).

Full storage is the following obvious scheme: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if $uplo = 'U'$, a_{ij} is stored in $a(i, j)$ for $i \leq j$, other elements of a need not be set.

if $uplo = 'L'$, a_{ij} is stored in $a(i, j)$ for $j \leq i$, other elements of a need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array ap :

if $uplo = 'U'$, a_{ij} is stored in $ap(i+j(j-1)/2)$ for $i \leq j$

if `uplo = 'L'`, a_{ij} is stored in $ap(i + (2*n-j)*(j-1)/2)$ for $j \leq i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in *p*.

Band storage is as follows: an m -by- n band matrix with kl non-zero sub-diagonals and ku non-zero super-diagonals is stored compactly in a two-dimensional array *ab* with $kl+ku+1$ rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array. Thus,

a_{ij} is stored in $ab(kl+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

Use the band storage scheme only when kl and ku are much less than the matrix size n . Although the routines work correctly for all values of kl and ku , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6$, $kl = 2$, $ku = 1$

Array elements marked * are not used by the routines:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0						
a_{21}	a_{22}	a_{23}	0	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
a_{31}	a_{42}	a_{43}	a_{34}	0	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{31}	a_{42}	a_{53}	a_{64}	*	*
0	0	0	a_{64}	a_{65}	a_{66}						

When a general band matrix is supplied for *LU factorization*, space must be allowed to store kl additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $kl + ku$ super-diagonals. Thus,

a_{ij} is stored in $ab(kl+ku+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

The band storage scheme for LU factorization is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	*	*	+	+	+
a_{21}	a_{22}	a_{23}	0	0	0	*	*	+	+	+	+
a_{31}	a_{42}	a_{43}	a_{34}	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	0	a_{64}	a_{65}	a_{66}	a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

*	*	*	u_{14}	u_{25}	u_{36}
*	*	u_{13}	u_{24}	u_{35}	u_{46}
*	u_{12}	u_{23}	u_{34}	u_{45}	u_{56}
u_{11}	u_{22}	u_{33}	u_{44}	u_{55}	u_{66}
m_{21}	m_{32}	m_{43}	m_{54}	m_{65}	*
m_{31}	m_{42}	m_{53}	m_{64}	*	*

where u_{ij} are the elements of the upper triangular matrix U, and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $kl = 0$ if upper triangular, or $ku = 0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* = 'U', a_{ij} is stored in $ab(k+1+i-j, j)$ for $\max(1, j-k) \leq i \leq j$

if $uplo = 'L'$, a_{ij} is stored in $ab(1+i-j, j)$ for $j \leq i \leq \min(n, j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in b .

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n'	normal (no conjugation, no transposition)
'T' or 't'	transpose
'C' or 'c'	conjugate transpose.

Example B-3 Two-Dimensional Complex Array

Suppose $A(1:5, 1:4)$ is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let $transa$ be the transposition parameter, m be the number of rows, n be the number of columns, and lda be the leading dimension. Then if

$transa = 'N'$, $m = 4$, $n = 2$, and $lda = 5$, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'T'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (2.1, 0.21) & (3.1, 0.31) & (4.1, 0.41) \\ (1.2, 0.12) & (2.2, 0.22) & (3.2, 0.32) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'C'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array `A` above is declared as `COMPLEX A (5,4)`.

Then if `transa = 'N'`, `m = 3`, `n = 4`, and `lda = 4`, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Code Examples

This appendix presents code examples of using some Intel MKL routines and functions. You can find here example code written in both Fortran and C.

Currently, the appendix includes the following sections:

- [BLAS Code Examples](#)
- [PARDISO Code Examples](#)
- [Direct Sparse Solver Code Examples](#)
- [Iterative Sparse Solver Code Examples](#)
- [Preconditioner Code Examples](#)
- [Fourier Transform Functions Code Examples](#)
- [Interval Linear Solvers Code Examples](#)
- [PDE Support Code Examples](#).

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example C-1. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors x and y .

Parameters

n	Specifies the number of elements in vectors x and y .
$incx$	Specifies the increment for the elements of x .

Parameters

incy Specifies the increment for the elements of *y*.

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
    x(i) = 2.0e0
    y(i) = 1.0e0
end do
res = sdot (n, x, incx, y, incy)
print*, `SDOT = `, res
end
```

As a result of this program execution, the following line is printed:

SDOT = 10.000

Example C-2. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine *scopy*. This routine performs a vector-vector operation of copying a single-precision real vector *x* to a vector *y*.

Parameters

n Specifies the number of elements in vectors *x* and *y*.

incx Specifies the increment for the elements of *x*.

Parameters

incy Specifies the increment for the elements of *y*.

```
program copy_main
real x(10), y(10)
integer n, incx, incy, i
n = 3
incx = 3
incy = 1
do i = 1, 10
    x(i) = i
end do
call scopy (n, x, incx, y, incy)
print*, `Y = `, (y(i), i = 1, n)
end
```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example C-3. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

$a := \alpha x y' + a.$

Parameters

alpha Specifies a scalar *alpha*.
x *m*-element vector.
y *n*-element vector.

Parameters

a *m*-by-*n* matrix.

```
program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx,
incy, i, j, lda
m = 2
n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10
    x(i) = 1.0
    y(i) = 1.0
end do
do i = 1, m
    do j = 1, n
        a(i,j) = j
    end do
end do
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A: `
do i = 1, m
    print*, (a(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

```
1.50000 2.50000 3.50000
```

```
1.50000 2.50000 3.50000
```

Example C-4. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

$c := \alpha a a' + \beta c.$

Parameters

alpha Specifies a scalar *alpha*.

beta Specifies a scalar *beta*.

a Symmetric matrix

b *m*-by-*n* matrix

Parameters

c *m*-by-*n* matrix

```
program symm_main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3
alpha = 0.5
beta = 2.0
do i = 1, m
    do j = 1, m
        a(i,j) = 1.0
    end do
end do
do i = 1, m
    do j = 1, n
        c(i,j) = 1.0
        b(i,j) = 2.0
    end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
```

```
print*, `Matrix C: `  
do i = 1, m  
    print*, (c(i,j), j = 1, n)  
end do  
end
```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

```
5.00000 5.00000  
5.00000 5.00000  
5.00000 5.00000
```

The following example illustrates a call from a C program to the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example C-5. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure *c*.

```
#define N 5

void main()
{

    int n, inca = 1, incb = 1, i;

    typedef struct{ double re; double im; } complex16;
    complex16 a[N], b[N], c;

    void zdotc();

    n = N;
    for( i = 0; i < n; i++ ){
        a[i].re = (double)i; a[i].im = (double)i * 2.0;
        b[i].re = (double)(n - i); b[i].im = (double)i * 2.0;
    }

    zdotc( &c, &n, a, &inca, b, &incb );

    printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.re, c.im );
}
```

NOTE. Instead of calling BLAS directly from C programs, you might wish to use the CBLAS interface; this is the supported way of calling BLAS from C. For more information about CBLAS, see [Appendix D](#), which presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

PARDISO Code Examples

This section presents code examples of using the PARDISO direct solver for computing solutions of linear systems with sparse matrices. For description of this solver, refer to Chapter 8 of the manual.

Examples for Sparse Symmetric Linear Systems

In this section two examples (Fortran, C) are provided to solve symmetric linear systems with PARDISO. To solve the systems of equations $Ax = b$, where

$$A = \begin{bmatrix} 7.0 & 0.0 & 1.0 & 0.0 & 0.0 & 2.0 & 7.0 & 0.0 \\ 0.0 & -4.0 & 8.0 & 0.0 & 2.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 8.0 & 1.0 & 0.0 & 0.0 & 0.0 & 0.0 & 5.0 \\ 0.0 & 0.0 & 0.0 & 7.0 & 0.0 & 0.0 & 9.0 & 0.0 \\ 0.0 & 2.0 & 0.0 & 0.0 & 5.0 & 1.0 & 5.0 & 0.0 \\ 2.0 & 0.0 & 0.0 & 0.0 & 1.0 & -1.0 & .0 & 5.0 \\ 7.0 & 0.0 & 0.0 & 9.0 & 5.0 & 0.0 & 11.0 & 0.0 \\ 0.0 & 0.0 & 5.0 & 0.0 & 0.0 & 5.0 & 0.0 & 5.0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \end{bmatrix}$$

Example Results for Symmetric Systems

Upon successful execution of the solver, the result of the solution x is as follows

Reordering completed ...

Number of nonzeros in factors = 30

Number of factorization MFLOPS = 0

Factorization completed ...

Solve completed ...

The solution of the system is

$x(1) = -0.0418602013$

$x(2) = -0.00341312416$

$x(3) = 0.117250377$

$x(4) = -0.11263958$

$x(5) = 0.0241722445$

$x(6) = -0.10763334$

$x(7) = 0.198719673$

$x(8) = 0.190382964$

Examples for Sparse Unsymmetric Linear Systems

In this section two examples (Fortran, C) are provided to solve unsymmetric linear systems with PARDISO. To solve the systems of equations $Ax = b$, where

$$A = \begin{bmatrix} 1.0 & -1.0 & 0.0 & -3.0 & 0.0 \\ -2.0 & 5.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 4.0 & 6.0 & 4.0 \\ -4.0 & 0.0 & 2.0 & 7.0 & 0.0 \\ 0.0 & 8.0 & 0.0 & 0.0 & -5.0 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \\ 1.0 \end{bmatrix}$$

Example Results for Unsymmetric Systems

Upon successful execution of the solver, the result of the solution x is as follows

Reordering completed ...

Number of nonzeros in factors = 21

Number of factorization MFLOPS = 0

Factorization completed ...

Solve completed ...

The solution of the system is

$x(1) = -0.522321429$

$x(2) = -0.00892857143$

$x(3) = 1.22098214$

$x(4) = -0.504464286$

$x(5) = -0.214285714$

Direct Sparse Solver Code Examples

This section contains example code in FORTRAN 77, Fortran 90 and C. For description of the sparse solver routines used in this code, refer to "Direct Sparse Solver (DSS) Interface Routines" in Chapter 8 of the manual. The example code solves the equations presented in Direct Method section of Appendix A - a symmetric positive definite system of equations $Ax = b$ with a sparse matrix, where

$$A = \begin{bmatrix} 9 & 1.5 & 6 & 0.75 & 3 \\ 1.5 & 0.5 & 0 & 0 & 0 \\ 6 & 0 & 12 & 0 & 0 \\ 0.75 & 0 & 0 & 0.625 & 0 \\ 3 & 0 & 0 & 0 & 16 \end{bmatrix} \text{ and } B = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

Example results for symmetric systems

Upon successful execution of the solver, the determinant and the result of the solution array are as follows

```

pow of determinant is      0.000
base of determinant is      2.250
Determinant is      2.250
Solution Array:  -326.333   983.000  163.417   398.000   61.500

```

Example C-10. FORTRAN 77 example to Solve Symmetric Positive Definite System

Iterative Sparse Solver Code Examples

This section contains example code in FORTRAN 77 and C. For description of the iterative sparse solver routines based on the reverse communication interface (RCI ISS) used in this code, refer to "Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)" in Chapter 8 of the manual .

Example of Use RCI (Preconditioned) Conjugate Gradient Solver for Systems with Single Right Hand Side

Example results for symmetric positive definite systems. Upon successful execution of the solver, the result of the solution array is as follows:

The system is successfully solved

The following solution obtained

1.000	0.000	1.000	0.000
1.000	0.000	1.000	0.000

Expected solution

1.000	0.000	1.000	0.000
1.000	0.000	1.000	0.000

Number of iterations: 8

Examples of Use RCI (Preconditioned) Conjugate Gradient Solver for Systems with Multiple Right Hand Sizes (MRHS)

Example results for symmetric positive definite systems. Upon successful execution of the solver, the result of the solution array is as follows:

The system is successfully solved

The following solution obtained

1.000	0.000	1.000	0.000
1.000	0.000	1.000	0.000
0.000	2.000	0.000	2.000
0.000	2.000	0.000	2.000

Expected solution

1.000	0.000	1.000	0.000
1.000	0.000	1.000	0.000
0.000	2.000	0.000	2.000
0.000	2.000	0.000	2.000

Example C-14a. Fortran Example to Solve Symmetric Positive Definite System with Multiple Right Hand Sizes (MRHS). No Preconditioning, No User-Defined Stopping Tests.

Fortran Example of Using RCI (Preconditioned) Flexible Generalized Minimal Residual Solver.

Fortran example results for a non-symmetric indefinite system. Upon successful execution of the solver, the following result is printed (up to rounding errors that depend on the computer system used):

```

-----
The SIMPLEST example of usage of RCI FGMRES solver
to solve a non-symmetric indefinite non-degenerate
algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:
As IPAR(8)=1, the automatic test for the maximal number of
iterations will be performed
As IPAR(9)=1, the automatic residual test will be performed
+++
As IPAR(10)=0, the user-defined stopping test will not be
requested, thus, RCI_REQUEST will not take the value 2
+++
As IPAR(11)=0, the Preconditioned FGMRES iterations will not
be performed, thus, RCI_REQUEST will not take the value 3
+++
As IPAR(12)=1, the automatic test for the norm of the next
generated vector is not equal to zero up to rounding and computational

```

errors will be performed, thus, RCI_REQUEST will not take the value 4

+++

The system has been SUCCESSFULLY solved

The following solution has been obtained:

COMPUTED_SOLUTION(1)=-0.100E+01

COMPUTED_SOLUTION(2)= 0.100E+01

COMPUTED_SOLUTION(3)= 0.305E-15

COMPUTED_SOLUTION(4)= 0.100E+01

COMPUTED_SOLUTION(5)=-0.100E+01

The expected solution is:

EXPECTED_SOLUTION(1)=-0.100E+01

EXPECTED_SOLUTION(2)= 0.100E+01

EXPECTED_SOLUTION(3)= 0.000E+00

EXPECTED_SOLUTION(4)= 0.100E+01

EXPECTED_SOLUTION(5)=-0.100E+01

+++

Number of iterations: 5

C Example of Using RCI (Preconditioned) Flexible Generalized Minimal Residual Solver.

C example results for the same non-symmetric indefinite system as in the previous example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example the addresses for input/result are adjusted for user-defined

operations from `IPAR(22)` to `ipar[21]-1`, and from `IPAR(23)` to `ipar[22]-1`, respectively. Upon successful execution of the solver, the following result is printed (up to rounding errors that depend on the computer system used):

```
-----  
The SIMPLEST example of usage of RCI FGMRES solver  
  to solve a non-symmetric indefinite non-degenerate  
  algebraic system of linear equations  
-----  
  Some info about the current run of RCI FGMRES method:  
  
As ipar[7]=1, the automatic test for the maximal number of iterations will be performed  
+++  
As ipar[8]=1, the automatic residual test will be performed  
+++  
As ipar[9]=0, the user-defined stopping test will not be requested, thus,  
RCI_request will not take the value 2  
+++  
As ipar[10]=0, the Preconditioned FGMRES iterations will not  
be performed, thus, RCI_request will not take the value 3  
+++  
As ipar[11]=1, the automatic test for the norm of the next  
generated vector is not equal to zero up to rounding and computational  
errors will be performed, thus, RCI_request will not take the value 4  
+++  
  
The system has been SUCCESSFULLY solved  
  
The following solution has been obtained:  
computed_solution[0]=-1.000000e+000
```

```
computed_solution[1]=1.000000e+000  
computed_solution[2]=3.053113e-016  
computed_solution[3]=1.000000e+000  
computed_solution[4]=-1.000000e+000
```

The expected solution is:

```
expected_solution[0]=-1.000000e+000  
expected_solution[1]=1.000000e+000  
expected_solution[2]=0.000000e+000  
expected_solution[3]=1.000000e+000  
expected_solution[4]=-1.000000e+000
```

Number of iterations: 5

Fourier Transform Functions Code Examples

This section presents code examples of functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

FFT Code Examples

This section presents code examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter. Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

Example C-16 One-dimensional In-place FFT (Fortran Interface)

```
! Fortran example.

! 1D complex to complex, and real to conjugate even
Use MKL_DFTI
Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status

!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform

status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*
```

Example C-18 Two-dimensional FFT (Fortran Interface)

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

! Fortran example.

! 2D complex to complex, and real to conjugate even

Use MKL_DFTI

Complex :: X_2D(32,100)

Real :: Y_2D(34, 102)

Complex :: X(3200)

Real :: Y(3468)

Equivalence (X_2D, X)

Equivalence (Y_2D, Y)

type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle

Integer :: Status, L(2)

!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j=32,1<=k<=100

!...set L(1) = 32, L(2) = 100

!...the transform is a 32-by-100

! Perform a complex to complex transform

```
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
                             DFTI_COMPLEX, 2, L)
```

```
Status = DftiCommitDescriptor( My_Desc1_Handle)
```

```
Status = DftiComputeForward( My_Desc1_Handle, X)
```

```
Status = DftiFreeDescriptor(My_Desc1_Handle)
```

! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate even transform

```
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE,&
                               DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format
```

Example C-19 Two-dimensional FFT (C Interface)

```
/* C99 example */

#include "mkl_dfti.h"

float _Complex x[32][100];
float y[34][102];

DFTI_DESCRIPTOR *my_desc1_handle, my_desc2_handle;
long status, l[2];

//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;

status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
                             DFTI_COMPLEX, 2, l);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
                             DFTI_REAL, 2, l);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/
```

The following examples demonstrate how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of the `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

Example C-20 Changing Default Settings (Fortran)

The code below illustrates how this can be done:

```
! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle,&
DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor (My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)
```

Example C-21 Changing Default Settings (C)

```
/* C99 example */

#include "mkl_dfti.h"

float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;

/* or alternatively
DFTI_DESCRIPTOR *my_desc_handle;*/

long status;

//...put input data into x_in[j], 0 <= j < 32

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);

status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);

/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Example C-22 Using Status Checking Function

The [Example C-22](#) illustrates the use of the status checking functions described in [Chapter 11](#).

```
/* C */

DFTI_DESCRIPTOR_HANDLE desc;
long status, class_error, value;
char* error_message;
// . . . descriptor creation and other code
status = DftiGetValue( desc, DFTI_PRECISION, &value); //

class_error = DftiErrorClass(status, DFTI_NO_ERROR);
if (! class_error) {
    printf ("DftiGetValue() fixes the wrong situation and
           returns the corresponding value n");
    error_message = DftiErrorMessage(status);
    printf("error_message = %s \n", error_message);
}
// . . .

! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer value, status
character(DFTI_MAX_MESSAGE_LENGTH) error_message
logical class_error
! . . . descriptor creation and other code
status = DftiGetValue( desc, DFTI_PRECISION, value)
class_error = DftiErrorClass(status, DFTI_NO_ERROR)
if (.not. class_error) then
    print *, ' DftiGetValue() fixes the wrong situation and ',&
```

```
        'returns the corresponding value '  
    error_message = DftiErrorMessage(status)  
    print *, 'error_message = ', error_message  
endif
```

Example C-23. Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran

use mkl_dfti

Complex :: X_2D(20,40)
Complex :: X(800)

Equivalence (X_2D, X)

INTEGER :: STRIDE(2)

type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2

! ...

Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 20 )

Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 40 )

! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )

! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20

Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
```

```

Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )

/* C */
#include "mkl_dfti.h"
float _Complex x[20][40];
long stride[2];
long status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...

status = DftiCreateDescriptor( &desc_handle_dim1, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 20 );
status = DftiCreateDescriptor( &desc_handle_dim2, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 40 );

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;

status = DftiSetValue( desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_STRIDES, stride );

```

```
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride );
status = DftiCommitDescriptor( desc_handle_dim1 );
status = DftiComputeForward( desc_handle_dim1, x );
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue( desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 );
status = DftiSetValue( desc_handle_dim2,
DFTI_INPUT_DISTANCE, 40 );
status = DftiSetValue( desc_handle_dim2,
DFTI_OUTPUT_DISTANCE, 40 );
status = DftiCommitDescriptor( desc_handle_dim2 );
status = DftiComputeForward( desc_handle_dim2, x );
status = DftiFreeDescriptor( &Desc_Handle_dim1 );
status = DftiFreeDescriptor( &Desc_Handle_dim2 );
```

The following are examples of real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example C-24](#) is two-dimensional in-place transform and [Example C-24a](#) is two-dimensional out-of-place transform in Fortran interface. [Example C-25](#) is three-dimensional out-of-place transform in C interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Example C-24. Two-Dimensional REAL In-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate even
Use MKL_DFTI
Real :: X_2D(34,100) ! 34 = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X_2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.
```

Example C-24a. Two-Dimensional REAL Out-of-place FFT (Fortran Interface)

```

! Fortran example.
! 2D and real to conjugate even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)

! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate even
transform

Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_OUTPUT_STRIDES, strides_out)

```

```
Status = DftiCommitDescriptor(My_Desc_Handle)
Status = DftiComputeForward(My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.
```

Example C-25 Three-Dimensional REAL FFT (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float _Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
/* or alternatively
DFTI_DESCRIPTOR *my_desc_handle*/
long status, l[3];
long strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, l );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
```

```
status = DftiFreeDescriptor(&my_desc_handle);  
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9  
and is stored in complex matrix y in CCE format. */
```

Examples of Using Multi-Threading for FFT Computation

The following sample program shows how to employ internal threading in Intel MKL for FFT computation (see case "a" in ["Number of user threads"](#)).

To specify the number of threads inside Intel MKL, use the following settings:

set MKL_NUM_THREADS = 1 for one-threaded mode;

set MKL_NUM_THREADS = 4 for multi-threaded mode.

Note that the configuration parameter DFTI_NUMBER_OF_USER_THREADS must be equal to its default value 1.

Example C-26 Using Intel MKL Internal Threading Mode

```
#include "mkl_dfti.h"

void main () {

float x[200][100];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
long status, len[2];
//...put input data into x[j][k] 0<=j<=199, 0<=k<=99

len[0] = 200; len[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,DFTI_REAL, 2,
    len);
status = DftiCommitDescriptor(
my_desc1_handle);
status = DftiComputeForward(
my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
}
```

The following [Example C-27](#) and [Example C-27a](#) illustrate a parallel customer program with each descriptor instance used only in a single thread (see cases "b" and "c" in [Number of user threads](#)).

Specify the number of threads for [Example C-27](#) like this:

set `MKL_SERIAL = yes` (or `YES`) for Intel MKL to work in the single-threaded mode (recommended);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have its default value of 1.

Example C-27 Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL (case "a"). To achieve this, you need to set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

```
#include "mkl_dfti.h"
#include "omp.h"

void main ()
{
    float _Complex x[200][100];
    long len[2];
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;

    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel
    {
        DFTI_DESCRIPTOR_HANDLE my_desc_handle;
        long myStatus;
        int myID = omp_get_thread_num ();

myStatus    =  DftiCreateDescriptor (&my_desc_handle, DFTI_SINGLE,
DFTI_COMPLEX, 2, len);

        myStatus = DftiCommitDescriptor (my_desc_handle);
        myStatus = DftiComputeForward (my_desc_handle, &x[myID * len[0] * len[1]]);
        myStatus = DftiFreeDescriptor (&my_desc_handle);
    } /* End OpenMP parallel region */
}
```

```
}
```

Specify the number of threads for [Example C-27a](#) like this:

set `MKL_NUM_THREADS = 1` for Intel MKL to work in the single-threaded mode (obligatory);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have the default value of 1.

Example C-27a Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```
#include "mkl_dfti.h"

#include "omp.h"

void main ()
{
    float _Complex x[200][100];
    long len[2];
    long i;
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;
    DFTI_DESCRIPTOR_HANDLE my_desc_handle[4];
    long myStatus;

    for (i=0;i<3;i++) myStatus = DftiCreateDescriptor (&my_desc_handle[i], DFTI_SINGLE, DFTI_COMPLEX,
        2, len);

    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel
    {
        int myID = omp_get_thread_num ();
        myStatus = DftiCommitDescriptor (my_desc_handle[myID]);
        myStatus = DftiComputeForward (my_desc_handle[myID], &x[myID * len[0] * len[1]]);
    } /* End OpenMP parallel region */
    for (i=0;i<3;i++) myStatus = DftiFreeDescriptor (&my_desc_handle[i]);
}
```

The following [Example C-28](#) illustrates a parallel customer program with a common descriptor used in several threads (see case "d" in ["Number of user threads"](#)).

In this case, the number of threads, as well as any other configuration parameter, must not be changed after FFT initialization by the `DftiCommitDescriptor()` function is done.

Example C-28 Using Parallel Mode with a Common Descriptor

```
// set number of threads inside Intel MKL:
//rem set MKL_SERIAL = YES    -    is not required
// since one-threaded mode for Intel MKL is forced automatically
// set OMP_NUM_THREADS = 4    -    multi-threaded mode for customer

#include "mkl_dfti.h"
#include "omp.h"
void main ()
{
    float _Complex x[200][100];
    long status;
    DFTI_DESCRIPTOR_HANDLE desc_handle;
    int nThread = omp_get_max_threads ();
    long len[2];
    //...put input data into x[j][k] 0<=j<=199, 0<=k<=99
    len[0] = 50; len[1] = 100;

    status =
DftiCreateDescriptor (&desc_handle, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    status = DftiSetValue (desc_handle,
DFTI_NUMBER_OF_USER_THREADS, nThread);
    status = DftiCommitDescriptor (desc_handle);

    // each thread calculates real FFT for matrix (50*100)
    #pragma omp parallel num_threads(nThread)
    {
```

```
long myStatus;

int myID = omp_get_thread_num ();

myStatus = DftiComputeForward (desc_handle, &x[myID * len[0] * len[1]]);
} /* End OpenMP parallel region */

status = DftiFreeDescriptor (&desc_handle);
}
```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

Example 29. 2D Out-of-place Cluster FFT Computation

```

DFTI_DESCRIPTOR_DM_HANDLE desc;

long len[2],v,i,j,n,s;

Complex *in,*out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,2,1 en);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
    for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);

```

```
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();
```

Example 30. 1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```
DFTI_DESCRIPTOR_DM_HANDLE desc;

long len,v,i,n_out,s_out;

Complex *in,*work;

MPI_Init(...);

// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,1,1,en);

// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
work=(Complex*)malloc(v*sizeof(Complex));

// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);

// Set work array as a workspace
DftiSetValueDM(desc,CDFT_WORKSPACE,work);

// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0;i<n;i++) in[i]=f(i+s);

// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);

DftiComputeForwardDM(desc,in);

DftiGetValueDM(desc,CDFT_LOCAL_OUT_NX,&n_out);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_X_START,&s_out);

// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
```

```
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();
```

Auxiliary Data Transformations

This section presents code examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Example C-30a Conversion from Cartesian to polar representation of complex data

```
// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp( I*phi )
#include <mkl_vml.h>

void

variant1_Cartesian2Polar(int n,const double *re,const double *im,
                        double *r,double *phi)
{
    vdHypot(n,re,im,r);          // compute radii r[]
    vdAtan2(n,re,im,phi);        // compute phases phi[]
}

void
```

```
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                        double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);           // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_re,temp_im,phi); // compute phases phi[]
}
```

Example C-30b Conversion from polar to Cartesian representation of complex data

```
// Polar->Cartesian conversion of complex data.
// Polar representation:  $z = r * \exp(I * \phi)$ 
// Cartesian representation:  $z = \text{re} + I * \text{im}$ 
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n, const double *r, const double *phi,
                        double *re, double *im)
{
    vdSinCos(n, phi, im, re);    // compute direction, i.e.  $z[]/abs(z[])$ 
    vdMul(n, r, re, re);        // scale real part
    vdMul(n, r, im, im);        // scale imaginary part
}

void
variant2_Polar2Cartesian(int n, const double *r, const double *phi,
                        MKL_Complex16 *z,
                        double *temp_re, double *temp_im)
{
    vdSinCos(n, phi, temp_im, temp_re); // compute direction, i.e.  $z[]/abs(z[])$ 
    vdMul(n, r, temp_im, temp_im); // scale imaginary part
    vdMul(n, r, temp_re, temp_re); // scale real part
    vdUnpackI(n, temp_re, (double*)z + 0, 2); // fill in result.re
    vdUnpackI(n, temp_im, (double*)z + 1, 2); // fill in result.im
}
```

Interval Linear Solvers Code Examples

This section presents code examples of using the routines described in “[Interval Linear Solvers](#)”. These routines are intended for computing enclosures and estimates of the solution sets to interval linear systems of equations as well as for checking properties of interval matrices and their inversion.

Example C-31. Interval Gauss-Seidel method

Given an interval system of linear algebraic equations, interval Gauss-Seidel method (implemented as `?gegss` routine) is often applied for enclosing a desired portion of the solution set that is bounded by a prescribed interval box.

Consider the following interval linear system of equations

$$\begin{pmatrix} [2, 3] & [0, 1] \\ [1, 2] & [2, 3] \end{pmatrix} x = \begin{pmatrix} [0, 120] \\ [60, 240] \end{pmatrix}$$

proposed first by E. Hansen (see [Hansen92](#)). Does its solution set intersect the interval box

$$\begin{pmatrix} [0, 200] \\ [0, 200] \end{pmatrix} ?$$

The following sample program answers the above question.

```

PROGRAM DIGEGSS_EXAMPLE
!
! Example program enclosing the solution set to a square interval
! linear system by interval Gauss-Seidel iterative method
!
!-----!
USE INTERVAL_ARITHMETIC
IMPLICIT NONE
!-----!
INTEGER, PARAMETER :: DIM = 2
INTEGER :: NRHS, LDA, LDB, NITS,
INFO, I, J
REAL(8) :: EPSILON
TYPE(D_INTERVAL) :: A(DIM,DIM), B(DIM,1),
ENCL(DIM,1)
CHARACTER(1) :: TRANS
!-----!
PRINT 300
!-----!
! !
! Initializing the input data - !
! !
TRANS = 'N'
NRHS = 2
A(1,1) = DINTERVAL(2.,3.); A(1,2) = DINTERVAL(0.,1.);
A(2,1) = DINTERVAL(0.,1.); A(2,2) = DINTERVAL(2.,3.);
LDA = 2

```

```

B(1,1) = DINTERVAL(0.,120.); B(2,1) = DINTERVAL(60.,240.);

LDB = 2

EPSILON = 1.D-6

NITS = 20

!-----!

!

! Assigning the bounding box for the solution set -
DO I = 1, DIM
ENCL(I,1) = DINTERVAL(0.,200.)
END DO

!-----!

CALL DIGEGSS(TRANS,
DIM, NRHS, A, LDA, B, LDB, ENCL, EPSILON, NITS, INFO )

!-----!

!

! Outputting the solution
IF( INFO /= 0 ) THEN
PRINT 400
ELSE
PRINT 600
DO I = 1, DIM
PRINT *, '[', B(I,1), ']'
END DO
END IF

!-----!

300 FORMAT (/, ' **** SOLVING INTERVAL LINEAR SYSTEM **** ', /, &
' by interval Gauss-Seidel method ')
400 FORMAT (/, ' The interval Gauss-Seidel method fails. ')

```

```
600 FORMAT (/, ' Outer interval estimate of the solution set:',/)
!-----!
END PROGRAM DIGEGSS_EXAMPLE
```

Assigning double-precision intervals to the entries of the matrix A and right-hand side vector B is carried out by `DINTERVAL` function that turns two real numbers into the interval having these reals as endpoints. Running the above code produces the answer

```
**** SOLVING INTERVAL LINEAR SYSTEM****
by interval Gauss-Seidel method
Outer interval estimate of the solution set:
[ 0.000000000000000E+000 60.0000000000000 ]
[ 0.000000000000000E+000 120.000000000000 ]
```

One can make sure that the resulting box really encloses the required portion of the solution set after having a look at the corresponding graph from the paper [Hansen92](#). Moreover, it is even the tightest possible enclosure.

Example C-32. Hansen-Bliek-Rohn procedure

The following Fortran 90 program illustrates the use of `digehbs` routine implementing “semiinterval” Hansen-Bliek-Rohn procedure for outer interval estimation of the solution sets to interval linear systems.

```
PROGRAM DIGEHBS_EXAMPLE
!
! Example program for enclosing the solution set to square interval
! interval system of equations by Hansen-Bliek-Rohn procedure
!
!-----!
USE INTERVAL_ARITHMETIC
IMPLICIT NONE
!-----!
INTEGER, PARAMETER :: DIM = 2
INTEGER :: LDA, LDB, INFO, I, J
TYPE(D_INTERVAL), ALLOCATABLE ::
A(:, :), B(:)
CHARACTER(1) :: TRANS
!-----!
PRINT 300
!-----!
!
! Initializing the input data -
!
TRANS = 'N'
ALLOCATE( A(DIM,DIM), B(DIM) )
A(1,1) = DINTERVAL(2.,4.); A(1,2) = DINTERVAL(-2.,1.)
A(2,1) = DINTERVAL(-1.,2.); A(2,2) = DINTERVAL(2.,2.)
LDA = 2
```

```

B(1) = DINTERVAL(0.,2.); B(2) = DINTERVAL(0.,2.)

LDB = 2

!-----!

CALL DIGEHBS( TRANS, DIM, A, LDA,
B, LDB, INFO )

!-----!

IF( INFO /= 0 ) THEN
PRINT 400
ELSE
PRINT 600
DO I = 1, DIM
PRINT *, I, ' ) [', B(I), ']'
END DO
END IF

!-----!

DEALLOCATE( A, B )

!-----!

300 FORMAT (/, ' **** SOLVING INTERVAL LINEAR SYSTEM ****',/, &
' by Hansen-Bliek-Rohn procedure ',/)
400 FORMAT (/, ' The matrix of the system is not an H-matrix',/, &
' Hansen-Bliek-Rohn procedure fails. ',/)
600 FORMAT (/, ' Enclosure of the solution set: ',/)

!-----!

END PROGRAM DIGEHBS_EXAMPLE

```

However, the output of the program looks like

```
**** SOLVING INTERVAL LINEAR SYSTEM****
```

by Hansen-Bliek-Rohn procedure

The matrix of the system is not an H-matrix,

Hansen-Bliek-Rohn procedure fails.

This result is obtained because the program is applied to the interval linear system

$$\begin{pmatrix} [2, 4] & [-2, 1] \\ [-1, 2] & [2, 4] \end{pmatrix} \mathbf{x} = \begin{pmatrix} [0, 2] \\ [0, 2] \end{pmatrix}$$

where the interval matrix is not an H-matrix (that is, it does not have diagonal dominance).

However, preconditioning by `digemip` routine helps to resolve the problem. The following modified program, which incorporates preliminary preconditioning of the interval linear system under solution, makes the matrix diagonally dominant and produces an acceptable answer to the problem.

```
PROGRAM DIGEMIP_DIGEHS_EXAMPLE
!
! Example program for enclosing the solution set to square interval
! interval system of equations by Hansen-Bliek-Rohn procedure
!
!-----!
USE INTERVAL_ARITHMETIC
IMPLICIT NONE
!-----!
INTEGER, PARAMETER :: DIM = 2, NRHS = 1
INTEGER :: LDA, LDB, INFO, I, J
TYPE(D_INTERVAL), ALLOCATABLE ::
A(:, :), B(:)
CHARACTER(1) :: TRANS
!-----!
PRINT 300
!-----!
!
! Initializing the input data -
!
TRANS = 'N'
ALLOCATE( A(DIM,DIM), B(DIM) )
A(1,1) = DINTERVAL(2.,4.); A(1,2) = DINTERVAL(-2.,1.)
A(2,1) = DINTERVAL(-1.,2.); A(2,2) = DINTERVAL(2.,2.)
LDA = 2
B(1) = DINTERVAL(0.,2.); B(2) = DINTERVAL(0.,2.)
```

```

LDB = 2

!-----!

CALL DIGEMIP( DIM, NRHS, A, LDA,
B, LDB, INFO )
CALL DIGEHBS( TRANS, DIM, A, LDA,
B, LDB, INFO )

!-----!

IF( INFO /= 0 ) THEN
PRINT 400
ELSE
PRINT 600
DO I = 1, DIM
PRINT *, I, ' ) [', B(I), ']'
END DO
END IF

DEALLOCATE( A, B )

!-----!

300 FORMAT (/, ' **** SOLVING INTERVAL LINEAR SYSTEM ****',/, &
' by Hansen-Bliek-Rohn procedure ',/)
400 FORMAT (/, ' The matrix of the system is not an H-matrix',/, &
' Hansen-Bliek-Rohn procedure fails. ',/)
600 FORMAT (/, ' Enclosure of the solution set: ',/)

!-----!

END PROGRAM DIGEMIP_DIGEHS_EXAMPLE

```

This time, the output of the program is

```
**** SOLVING INTERVAL LINEAR SYSTEM****
```

by Hansen-Bliek-Rohn procedure

Enclosure of the solution set:

```
1 ) [ -4.23529411764708 10.7058823529412 ]
```

```
2 ) [ -6.70588235294119 10.8235294117647 ]
```

(the last digits may change for various computer architectures).

Example C-33. Computing enclosure for inverse interval matrix

Given an interval 2×2 matrix

$$\begin{pmatrix} 3 & [0, 1] \\ [1, 2] & [2, 3] \end{pmatrix}$$

the following Fortran 90 code computes an enclosure of its inverse interval matrix:

```

PROGRAM SIGESZI_EXAMPLE
!
!Example program inverting an interval matrix by Sczulz iterative procedure
!
!-----!
USE INTERVAL_ARITHMETIC
IMPLICIT NONE
!-----!
INTEGER, PARAMETER :: DIM = 2, LDA = 2
INTEGER :: INFO, I, J
TYPE(S_INTERVAL), ALLOCATABLE ::
A(:, :)
!-----!
PRINT 300
!-----!
!
! Initializing the input data -
!
ALLOCATE( A(LDA,DIM) )
A(1,1) = SINTERVAL(3.,3.); A(1,2) = SINTERVAL(0.,1.)
A(2,1) = SINTERVAL(1.,2.); A(2,2) = SINTERVAL(2.,3.)
!-----!
CALL SIGESZI ( DIM, A, LDA, INFO )
!-----!
PRINT 600
DO I = 1, DIM
PRINT *, ( '[', A(I,J), ']', J = 1,

```

```

DIM )
END DO
DEALLOCATE( A )
!-----!
300 FORMAT (/, ' **** INVERTING INTERVAL MATRIX ****',/, &
' by interval Schulz method ' )
400 FORMAT (/, ' Schulz inversion procedure failed. ',/)
600 FORMAT (/, ' Enclosure of the inverse matrix ',/)
!-----!
END PROGRAM SIGESZI_EXAMPLE

```

The output listing (with small variations depending on the architecture) looks as follows:

```

**** INVERTING INTERVAL MATRIX ****
by interval Schulz method
Enclosure of the inverse matrix
[ 0.2407409 0.5000001 ][ -0.2500000 0.1018518 ]
[ -0.5000000 5.5555239E-02 ][ 0.1388889 0.7500001 ]

```

At the same time, if we widen the (1,1) entry of the matrix to the interval [2, 3], the `sigeszi` procedure fails to compute a finite enclosure of the inverse to the new interval matrix

$$\begin{pmatrix} [2, 3] & [0, 1] \\ [1, 2] & [2, 3] \end{pmatrix}$$

Nevertheless, the interval linear system with such matrix can be successfully solved by specialized routines, for example, by interval Gauss method or interval Gauss-Seidel method (see [Example C-31](#)).

PDE Support Code Examples

This section presents code examples for routines described in the in the [“Partial Differential Equations Support” chapter](#). The examples are grouped in subsections

- [Trigonometric Transform Code Examples](#)
- [Poisson Library Code Examples](#).

Trigonometric Transforms Interface Code Examples

Code presented in this section computes solutions of three simple 1D Helmholtz problems with different boundary conditions: DD, NN and ND cases, where “D” denotes a Dirichlet boundary condition and “N” stands for a Neumann boundary condition. [Example C-34](#) implements the computations in C and [Example C-35](#) provides Fortran 90 code.

The algorithm of computing the solution uses [Trigonometric Transform routines](#), described in chapter 13. In the DD case, the sine transform is computed, the NN case uses the cosine transform and the ND case corresponds to the staggered cosine transform.

Other details of the Helmholtz problems being solved are printed out along with the computed solutions.

Upon successful execution of [Example C-34](#) the following text is printed out ([Example C-35](#) generates similar output):

Example of use of MKL Trigonometric Transforms

This example gives the solutions of the 1D differential problems
 with the equation $-u''+u=f(x)$, $0 < x < 1$,
 and with 3 types of boundary conditions:
 DD case: $u(0)=u(1)=0$,
 NN case: $u'(0)=u'(1)=0$,
 ND case: $u'(0)=u(1)=0$.

 In general, the error should be of order $O(1.0/n^{**2})$
 For this example, the value of n is 8
 The approximation error should be of order 5.0e-002 if everything is OK

 Note that n should be even to use Trigonometric Transforms !

DOUBLE PRECISION COMPUTATIONS

=====

The computed solution of DD problem is

u[0]= 0.000
 u[1]= 0.153
 u[2]= 0.524
 u[3]= 0.895
 u[4]= 1.049
 u[5]= 0.895

```
u[6]= 0.524
```

```
u[7]= 0.153
```

```
u[8]= 0.000
```

```
Error=4.873e-002
```

The computed solution of NN problem is

```
u[0]==-0.026
```

```
u[1]= 0.128
```

```
u[2]= 0.500
```

```
u[3]= 0.872
```

```
u[4]= 1.026
```

```
u[5]= 0.872
```

```
u[6]= 0.500
```

```
u[7]= 0.128
```

```
u[8]==-0.026
```

```
Error=2.583e-002
```

The computed solution of ND problem is

```
u[0]==-0.009
```

```
u[1]= 0.145
```

```
u[2]= 0.517
```

```
u[3]= 0.890
```

```
u[4]= 1.045
```

```
u[5]= 0.892
```

u[6]= 0.522

u[7]= 0.152

u[8]= 0.000

Error=4.470e-002

Example C-34 shows C code of the computations.

Example C-34. C Example to Solve a Set of 1D Helmholtz Problems

Poisson Library Code Examples

Cartesian case

The code below computes an approximate solution of a 2D Poisson problem

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = 8\pi^2 \sin 2\pi x \cdot \sin 2\pi y$$

in the rectangle $0 < x < 1, 0 < y < 1$.

The following boundary conditions are imposed for the problem:

- Dirichlet boundary condition

$$u(0, y) = u(1, y) = 1$$

for $0 \leq y \leq 1$.

- Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, 0) = -2\pi \sin 2\pi x, \frac{\partial u}{\partial n}(x, 1) = 2\pi \sin 2\pi x$$

for $0 < x < 1$.

The exact solution is known to be

$$u(x, y) = \sin 2\pi x \cdot \sin 2\pi y + 1$$

Example [C-36](#) implements the computations in C and Example [C-37](#) provides Fortran 90 code. Mind that PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of Intel MKL FFT interface.

The algorithm of computing the approximate solution of a Poisson Problem uses [Poisson Library routines](#), described in chapter 13. Details of the Poisson problem being solved and the errors are printed out between the computed solution and the exact one.

Upon successful execution of Example C-36 the following text is printed out (Example C-37 produces similar output):

Example of use of MKL Poisson Library

```
This example gives the solution of 2D Poisson problem
with the equation -u_xx-u_yy=f(x,y), 0<x<1, 0<y<1,
f(x,y)=(8*pi*pi)*sin(2*pi*x)*sin(2*pi*y),
and with the following boundary conditions:
  u(0,y)=u(1,y)=1 (Dirichlet boundary conditions),
-u_y(x,0)=-2.0*pi*sin(2*pi*x) (Neumann boundary condition),
  u_y(x,1)= 2.0*pi*sin(2*pi*x) (Neumann boundary condition).
```

```
-----
In general, the error should be of order O(1.0/nx^2+1.0/ny^2)
For this example, the value of nx=ny is 6
The approximation error should be of order 1.0e-01, if everything is OK
-----
```

DOUBLE PRECISION COMPUTATIONS

```
=====
The number of mesh intervals in x-direction is nx=6
The number of mesh intervals in y-direction is ny=6
```

```
In the mesh point (0.167,0.000) the error between the computed and the true solution
is equal to -7.505e-02
In the mesh point (0.167,0.167) the error between the computed and the true solution
is equal to  4.432e-02
In the mesh point (0.167,0.333) the error between the computed and the true solution
is equal to  6.309e-02
```

In the mesh point (0.167,0.500) the error between the computed and the true solution is equal to -5.551e-16

In the mesh point (0.167,0.667) the error between the computed and the true solution is equal to -6.309e-02

In the mesh point (0.167,0.833) the error between the computed and the true solution is equal to -4.432e-02

In the mesh point (0.167,1.000) the error between the computed and the true solution is equal to 7.505e-02

Double precision 2D Poisson example has successfully PASSED
through all steps of computation!

Note that actual figures in the error may slightly differ from the figures printed above depending on the architecture and operating system used to run the example.

Example [C-36](#) shows C code of the computations.

```

Spherical case

The code below computes an approximate solution of a Helmholtz problem on the entire sphere:

$$-\Delta_s u + u = 3 \cos \theta, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

with $a_\phi = 0$, $b_\phi = 2\pi$, $a_\theta = 0$, $b_\theta = \pi$, and a boundary condition

$$\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\substack{\theta \rightarrow 0 \\ \theta \rightarrow \pi}} = 0$$

at the poles (*periodic* case).

The exact solution is known to be $u(\phi, \theta) = \cos \theta$.

Example [C-38](#) implements the computations in C and Example [C-39](#) provides Fortran 90 code. Mind that PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of Intel MKL FFT interface.

The algorithm of computing the approximate solution of a Poisson Problem uses [Poisson Library routines](#), described in chapter 13. Details of the Poisson problem being solved and the errors are printed out between the computed solution and the exact one. Upon successful execution of Example C-38 the following text is printed out (Example C-39 produces similar output):

Example of use of MKL Poisson Library

This example gives the solution of Helmholtz problem on a whole sphere
 $0 < p < 2\pi$, $0 < t < \pi$, with Helmholtz coefficient $q=1$ and right-hand side
 $f(p,t)=3\cos(t)$

 In general, the error should be of order $O(1.0/np^2+1.0/nt^2)$

For this example, the value of $np=nt$ is 8

The approximation error should be of order $1.5e-01$, if everything is OK

 Note that np should be even to solve the PERIODIC problem!

 DOUBLE PRECISION COMPUTATIONS

=====

The number of mesh intervals in phi-direction is $np=8$

The number of mesh intervals in theta-direction is $nt=8$

In the mesh point (0.785,0.000) the error between the computed and the true solution
 is equal to $-1.402e-001$

In the mesh point (0.785,0.393) the error between the computed and the true solution
 is equal to $-3.097e-002$

In the mesh point (0.785,0.785) the error between the computed and the true solution
 is equal to $-6.036e-003$

In the mesh point (0.785,1.178) the error between the computed and the true solution is equal to 2.964e-004

In the mesh point (0.785,1.571) the error between the computed and the true solution is equal to 4.979e-017

In the mesh point (0.785,1.963) the error between the computed and the true solution is equal to -2.964e-004

In the mesh point (0.785,2.356) the error between the computed and the true solution is equal to 6.036e-003

In the mesh point (0.785,2.749) the error between the computed and the true solution is equal to 3.097e-002

In the mesh point (0.785,3.142) the error between the computed and the true solution is equal to 1.402e-001

Double precision Helmholtz example on a whole sphere has successfully PASSED through all steps of computation!

Note that actual figures in the error may slightly differ from the figures printed above depending on the architecture and operating system used to run the example.

Example [C-38](#) shows C code for the problem.

Example C-38. C Example to Solve Helmholtz Problem on a Sphere

      1 the computed and the true solution is equal to ', E10.3)
! End of the example code
end
```

Preconditioner Code Examples

This section contains example codes in FORTRAN 77 and C. For description of the preconditioner routines used in these codes, refer to "Preconditioners (Accelerators) based on Incomplete LU Factorization Techniques" in Chapter 8 of the manual.

Fortran Example of Using ILU0 Preconditioner with RCI FGMRES Solver

Example results for non-degenerate system. Upon successful execution of the solver, the output contains the following information:

```
-----
The FULLY ADVANCED example RCI FGMRES with ILU0 preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

Some info about the current run of RCI FGMRES method:

As IPAR(8)=0, the automatic test for the maximal number of iterations will be skipped
+++

As IPAR(9)=0, the automatic residual test will be skipped
+++

As IPAR(10)=1, the user-defined stopping test will be requested via RCI_REQUEST=2
+++

As IPAR(11)=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_REQUEST=3
+++

As IPAR(12)=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_REQUEST=4
+++

The system has been solved

The following solution has been obtained
COMPUTED_SOLUTION(1)= 0.100E+01
COMPUTED_SOLUTION(2)= 0.100E+01
COMPUTED_SOLUTION(3)= 0.100E+01
```

```
COMPUTED_SOLUTION(4)= 0.100E+01
```

The expected solution is:

```
EXPECTED_SOLUTION(1)= 0.100E+01
```

```
EXPECTED_SOLUTION(2)= 0.100E+01
```

```
EXPECTED_SOLUTION(3)= 0.100E+01
```

```
EXPECTED_SOLUTION(4)= 0.100E+01
```

Number of iterations: 2

```
-----  
Fortran example of FGMRES with ILU0 preconditioner  
has successfully PASSED all stages of computations  
-----
```

NOTE. If the ILU0 preconditioner is not used, then the same code requires 7 iterations.

Example C-40. FORTRAN 77 Example to Solve Non-symmetric Non-degenerate Linear System

```

C-----
C Calculate ILU0 preconditioner.
C
      !ATTENTION!
C DCSRILU0 routine uses some IPAR, DPAR set by DFGMRES_INIT routine.
C Important for DCSRILU0 default entries set by DFGMRES_INIT are

```

```

C ipar(2) = 6 - output of error messages to the screen,
C ipar(6) = 1 - allow output of error messages,
C ipar(31)= 0 - abort DCSRILU0 calculations if routine meets zero diagonal element.
C
C If ILU0 is going to be used out of MKL FGMRES context, than the values
C of ipar(2), ipar(6), ipar(31), dpar(31), and dpar(32) should be user
C provided before the DCSRILU0 routine call.
C
C In this example, specific for DCSRILU0 entries are set in turn:
C ipar(31)= 1 - change small diagonal value to that given by dpar(32),
C dpar(31)= 1.D-20 instead of the default value set by DFGMRES_INIT.
C           It is a small value to compare a diagonal entry with it.
C dpar(32)= 1.D-16 instead of the default value set by DFGMRES_INIT.
C           It is the target value of the diagonal value if it is
C           small as compared to dpar(31) and the routine should change
C           it rather than abort DCSRILU0 calculations.
C-----

```

```

      IPAR(31)=1
      DPAR(31)=1.D-20
      DPAR(32)=1.D-16

      CALL DCSRILU0(N, A, IA, JA, BILU0, IPAR, DPAR, IERR)
      NRM2=DNRM2(MATSIZE, BILU0, INCX)

      IF(IERR.ne.0) THEN
        WRITE(*,'(A,A,I1)') ' Error after calculation of the',
1 ' preconditioner DCSRILU0',IERR
        GOTO 998
      
```

```
ENDIF

C-----
C Set the desired parameters:
C do the restart after 2 iterations
C LOGICAL parameters:
C do not do the stopping test for the maximal number of iterations
C do the Preconditioned iterations of FGMRES method
C Set parameter IPAR(11) for preconditioner call. For this example,
C it reduces the number of iterations.
C DOUBLE PRECISION parameters
C set the relative tolerance to 1.0D-3 instead of default value 1.0D-6
C NOTE. Preconditioner may increase the number of iterations for an
C arbitrary case of the system and initial guess and even ruin the
C convergence. It is user's responsibility to use a suitable preconditioner
C and to apply it skillfully.
C-----

      IPAR(15)=2
      IPAR(8)=0
      IPAR(11)=1
      DPAR(1)=1.0D-3

C Example of Using ILU0 Preconditioner with RCI FGMRES Solver

C example has the same non-degenerate system as in the previous FORTRAN 77 example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example we adjust the addresses for input/result for user-defined operations from `IPAR(22)` to `ipar[21]-1` and from `IPAR(23)` to `ipar[22]-1`, respectively. Specific to ILU0 preconditioner parameter entries are referred to as `ipar[30]`, `dpar[30]`, `dpar[31]`. Upon successful execution of the solver, the following information is printed (up to rounding errors that depend on the computer system):

```

-----
The FULLY ADVANCED example RCI FGMRES with ILU0 preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

```

Some info about the current run of RCI FGMRES method:

As ipar[7]=0, the automatic test for the maximal number of iterations will be skipped

+++

As ipar[8]=0, the automatic residual test will be skipped

+++

As ipar[9]=1 the user-defined stopping test will be requested via

RCI_request=2

+++

As ipar[10]=1, the Preconditioned FGMRES iterations will be performed, thus, the preconditioner action will be requested via RCI_request=3

+++

As ipar[11]=0, the automatic test for the norm of the next generated vector is not equal to zero up to rounding and computational errors will be skipped, thus, the user-defined test will be requested via RCI_request=4

+++

The system has been solved

The following solution has been obtained

computed_solution[0]=1.000000e+00

computed_solution[1]=1.000000e+00

computed_solution[2]=1.000000e+00

computed_solution[3]=1.000000e+00

The expected solution is:

expected_solution[0]=1.000000e+00

expected_solution[1]=1.000000e+00

expected_solution[2]=1.000000e+00

expected_solution[3]=1.000000e+00

Number of iterations: 2

C example of FGMRES with ILU0 preconditioner
has successfully PASSED all stages of computations

NOTE. If the ILU0 preconditioner is not used, then the same code requires 7 iterations.

Fortran Example of Using ILUT Preconditioner with RCI FGMRES Solver

Example results for non-degenerate system. Upon successful execution of the solver, the output contains the following information:

```

-----
The FULLY ADVANCED example RCI FGMRES with ILUT preconditioner
to solve the non-degenerate algebraic system of linear equations
-----

```

Some info about the current run of RCI FGMRES method:

As IPAR(8)=0, the automatic test for the maximal number of iterations will be skipped

+++

As IPAR(9)=0, the automatic residual test will be skipped

+++

As IPAR(10)=1, the user-defined stopping test will be requested via RCI_REQUEST=2

+++

As IPAR(11)=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via RCI_REQUEST=3

+++

As IPAR(12)=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via RCI_REQUEST=4

+++

The system has been solved

The following solution has been obtained:

COMPUTED_SOLUTION(1)= 0.1000020E+01

COMPUTED_SOLUTION(2)= 0.1000007E+01

COMPUTED_SOLUTION(3)= 0.1000006E+01

COMPUTED_SOLUTION(4)= 0.9999908E+00

The expected solution is:

EXPECTED_SOLUTION(1)= 0.1000000E+01

EXPECTED_SOLUTION(2)= 0.1000000E+01

EXPECTED_SOLUTION(3)= 0.1000000E+01

EXPECTED_SOLUTION(4)= 0.1000000E+01

Number of iterations: 4

Fortran example of FGMRES with ILUT preconditioner
has successfully PASSED all stages of computations

NOTE. If the ILUT preconditioner is not used, then the same code requires 10 iterations.

Example C-42. Fortran Example to Solve Non-symmetric Non-degenerate Linear System

C Example of Using ILUT Preconditioner with RCI FGMRES Solver

C example has the same non-degenerate system as in the previous FORTRAN 77 example. The results are the same up to the notational convention between C and Fortran. Please pay special attention to how it is recommended to handle the differences between the Fortran and C arrays. Specifically, in this example we adjust the addresses for input/result for user-defined operations from `IPAR(22)` to `ipar[21]-1` and from `IPAR(23)` to `ipar[22]-1`, respectively. Specific to

ILUT preconditioner parameter entries are referred to as *ipar*[30], *dpar*[30], *dpar*[31]. Upon successful execution of the solver, the following information is printed (up to rounding errors that depend on the computer system):

```
-----  
The FULLY ADVANCED example RCI FGMRES with ILUT  
preconditioner to solve  
the non-degenerate algebraic system of linear equations  
-----
```

Some info about the current run of RCI FGMRES method:

As *ipar*[7]=0, the automatic test for the maximal number of iterations will be
skipped

+++

As *ipar*[8]=0, the automatic residual test will be skipped

+++

As *ipar*[9]=1, the user-defined stopping test will be requested via

RCI_request=2

+++

As *ipar*[10]=1, the Preconditioned FGMRES iterations will be performed, thus,
the preconditioner action will be requested via *RCI_request*=3

+++

As *ipar*[11]=0, the automatic test for the norm of the next generated vector is
not equal to zero up to rounding and computational errors will be skipped,
thus, the user-defined test will be requested via *RCI_request*=4

+++

The system has been solved

The following solution has been obtained:

```
computed_solution[0]=1.000020e+00
computed_solution[1]=1.000007e+00
computed_solution[2]=1.000006e+00
computed_solution[3]=9.99908e-01
```

The expected solution is:

```
expected_solution[0]=1.000000e+00
expected_solution[1]=1.000000e+00
expected_solution[2]=1.000000e+00
expected_solution[3]=1.000000e+00
```

Number of iterations: 4

```
-----
C example of FGMRES with ILUT preconditioner
has successfully PASSED all stages of computations
-----
```

NOTE. If the ILUT preconditioner is not used, then the same code requires 10 iterations.

Example C-43. C Example to Solve Non-symmetric Non-degenerate Linear System

CBLAS Interface to the BLAS

This appendix presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

Similar to BLAS, the CBLAS interface includes the following levels of functions:

- “Level 1 CBLAS” (vector-vector operations)
- “Level 2 CBLAS” (matrix-vector operations)
- “Level 3 CBLAS” (matrix-matrix operations).
- “Sparse CBLAS” (operations on sparse vectors).

To obtain the C interface, the Fortran routine names are prefixed with `cblas_` (for example, `dasum` becomes `cblas_dasum`). Names of all CBLAS functions are in lowercase letters.

Complex functions `?dotc` and `?dotu` become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with `_sub`. For example, the BLAS function `cdotc` corresponds to `cblas_cdotc_sub`.

In the descriptions of CBLAS interfaces, links provided for each function group lead to the descriptions of the respective Fortran-interface BLAS functions.

CBLAS Arguments

The arguments of CBLAS functions obey the following rules:

- Input arguments are declared with the `const` modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.
- Level 2 and Level 3 routines acquire an additional parameter of type `CBLAS_ORDER` as their first argument. This parameter specifies whether two-dimensional arrays are row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

Enumerated Types

The CBLAS interface uses the following enumerated types:

```
enum CBLAS_ORDER {
    CblasRowMajor=101, /* row-major arrays */
    CblasColMajor=102}; /* column-major arrays */

enum CBLAS_TRANSPOSE {
    CblasNoTrans=111, /* trans='N' */
    CblasTrans=112, /* trans='T' */
    CblasConjTrans=113}; /* trans='C' */

enum CBLAS_UPLO {
    CblasUpper=121, /* uplo ='U' */
    CblasLower=122}; /* uplo ='L' */

enum CBLAS_DIAG {
    CblasNonUnit=131, /* diag ='N' */
    CblasUnit=132}; /* diag ='U' */

enum CBLAS_SIDE {
    CblasLeft=141, /* side ='L' */
    CblasRight=142}; /* side ='R' */
```

Level 1 CBLAS

This is an interface to “[BLAS Level 1 Routines and Functions](#)”, which perform basic vector-vector operations.

?asum

```
float cblas_sasum(const int N, const float *X, const int incX);
double cblas_dasum(const int N, const double *X, const int incX);
float cblas_scasum(const int N, const void *X, const int incX);
double cblas_dzasum(const int N, const void *X, const int incX);
```

?axpy

```
void cblas_saxpy(const int N, const float alpha, const float *X, const int incX, float *Y,
  const int incY);

void cblas_daxpy(const int N, const double alpha, const double *X, const int incX, double
  *Y, const int incY);

void cblas_caxpy(const int N, const void *alpha, const void *X, const int incX, void *Y,
  const int incY);

void cblas_zaxpy(const int N, const void *alpha, const void *X, const int incX, void *Y,
  const int incY);
```

?copy

```
void cblas_scopy(const int N, const float *X, const int incX, float *Y, const int incY);
void cblas_dcopy(const int N, const double *X, const int incX, double *Y, const int incY);
void cblas_ccopy(const int N, const void *X, const int incX, void *Y, const int incY);
void cblas_zcopy(const int N, const void *X, const int incX, void *Y, const int incY);
```

?dot

```
float cblas_sdot(const int N, const float *X, const int incX, const float *Y, const int
  incY);

double cblas_ddot(const int N, const double *X, const int incX, const double *Y, const int
  incY);
```

?sdot

```
float cblas_sdsdot(const int N, const float *SB, const float *SX, const int incX, const
  float *SY, const int incY);

double cblas_dsdot(const int N, const float *SX, const int incX, const float *SY, const int
  incY);
```

?dotc

```
void cblas_cdotc_sub(const int N, const void *X, const int incX, const void *Y, const int
  incY, void *dotc);

void cblas_zdotc_sub(const int N, const void *X, const int incX, const void *Y, const int
  incY, void *dotc);
```

?dotu

```
void cblas_cdotu_sub(const int N, const void *X, const int incX, const void *Y, const int incY, void *dotu);
```

```
void cblas_zdotu_sub(const int N, const void *X, const int incX, const void *Y, const int incY, void *dotu);
```

?nrm2

```
float cblas_snrm2(const int N, const float *X, const int incX);
```

```
double cblas_dnrm2(const int N, const double *X, const int incX);
```

```
float cblas_scnrm2(const int N, const void *X, const int incX);
```

```
double cblas_dznrm2(const int N, const void *X, const int incX);
```

?rot

```
void cblas_srot(const int N, float *X, const int incX, float *Y, const int incY, const float c, const float s);
```

```
void cblas_drot(const int N, double *X, const int incX, double *Y, const int incY, const double c, const double s);
```

?rotg

```
void cblas_srotg(float *a, float *b, float *c, float *s);
```

```
void cblas_drotg(double *a, double *b, double *c, double *s);
```

?rotm

```
void cblas_srotm(const int N, float *X, const int incX, float *Y, const int incY, const float *P);
```

```
void cblas_drotm(const int N, double *X, const int incX, double *Y, const int incY, const double *P);
```

?rotmg

```
void cblas_srotmg(float *d1, float *d2, float *b1, const float b2, float *P);
```

```
void cblas_drotmg(double *d1, double *d2, double *b1, const double b2, double *P);
```

?scal

```
void cblas_sscal(const int N, const float alpha, float *X, const int incX);
```

```
void cblas_dscal(const int N, const double alpha, double *X, const int incX);
```

```
void cblas_cscal(const int N, const void *alpha, void *X, const int incX);
```

```
void cblas_zscal(const int N, const void *alpha, void *X, const int incX);
```

```
void cblas_csscal(const int N, const float alpha, void *X, const int incX);
```

```
void cblas_zdscal(const int N, const double alpha, void *X, const int incX);
```

?swap

```
void cblas_sswap(const int N, float *X, const int incX, float *Y, const int incY);
```

```
void cblas_dswap(const int N, double *X, const int incX, double *Y, const int incY);
```

```
void cblas_cswap(const int N, void *X, const int incX, void *Y, const int incY);
```

```
void cblas_zswap(const int N, void *X, const int incX, void *Y, const int incY);
```

i?amax

```
CBLAS_INDEX cblas_isamax(const int N, const float *X, const int incX);
```

```
CBLAS_INDEX cblas_idamax(const int N, const double *X, const int incX);
```

```
CBLAS_INDEX cblas_icamax(const int N, const void *X, const int incX);
```

```
CBLAS_INDEX cblas_izamax(const int N, const void *X, const int incX);
```

i?amin

```
CBLAS_INDEX cblas_isamin(const int N, const float *X, const int incX);
```

```
CBLAS_INDEX cblas_idamin(const int N, const double *X, const int incX);
```

```
CBLAS_INDEX cblas_icamin(const int N, const void *X, const int incX);
```

```
CBLAS_INDEX cblas_izamin(const int N, const void *X, const int incX);
```

Level 2 CBLAS

This is an interface to “BLAS Level 2 Routines”, which perform basic matrix-vector operations. Each C routine in this group has an additional parameter of type `CBLAS_ORDER` (the first argument) that determines whether the two-dimensional arrays use column-major or row-major storage.

?gbmv

```
void cblas_sgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const int N, const int KL, const int KU, const float alpha, const float *A, const int lda, const float *X, const int incX, const float beta, float *Y, const int incY);
```

```
void cblas_dgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const int N, const int KL, const int KU, const double alpha, const double *A, const int lda, const double *X, const int incX, const double beta, double *Y, const int incY);
```

```

Level 3 CBLAS

This is an interface to “[BLAS Level 3 Routines](#)”, which perform basic matrix-matrix operations. Each C routine in this group has an additional parameter of type `CBLAS_ORDER` (the first argument) that determines whether the two-dimensional arrays use column-major or row-major storage.

?gemm

```

```

Sparse CBLAS

This is an interface to “[Sparse BLAS Level 1 Routines and Functions](#)”, which perform a number of common vector operations on sparse vectors stored in compressed form.

Note that all index parameters, *indx*, are in C-type notation and vary in the range $[0..N-1]$.

?axpyi

```
void cblas_saxpy(const int N, const float alpha, const float *X, const int *indx, float *Y);
```

```
void cblas_daxpy(const int N, const double alpha, const double *X, const int *indx, double *Y);
```

```
void cblas_caxpy(const int N, const void *alpha, const void *X, const int *indx, void *Y);
```

```
void cblas_zaxpy(const int N, const void *alpha, const void *X, const int *indx, void *Y);
```

?doti

```
float cblas_sdoti(const int N, const float *X, const int *indx, const float *Y);
```

```
double cblas_ddoti(const int N, const double *X, const int *indx, const double *Y);
```

?dotci

```
void cblas_cdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
```

```
void cblas_zdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);
```

?dotui

```

void cblas_dsctr(const int N, const double *X, const int *indx, double *Y);
void cblas_csctr(const int N, const void *X, const int *indx, void *Y);
void cblas_zsctr(const int N, const void *X, const int *indx, void *Y);
```

Specific Features of Fortran 95 Interfaces for LAPACK Routines

Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see [“MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation”](#)). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::= <name of interface> '(' <arguments list> ')'  
<arguments list> ::= <first argument> {<argument>}*  
<first argument> ::= < identifier >  
<argument> ::= <required argument>|<optional argument>  
<required argument> ::= ',' <identifier>  
<optional argument> ::= '[,' <identifier> ']'  
<name of interface> ::= <identifier>
```

where defined notions are separated from definitions by `::=`, notion names are marked by angle brackets, terminals are given in quotes, and `{...}*` denotes repetition zero, one, or more times.

<first argument> and each *<required argument>* should be present in all calls of denoted interface, *<optional argument>* may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character `!`.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

Interfaces Identical to Netlib

Optimization Solvers Basics

Classical optimization methods are linear methods based on calculation of a direction and search for the best point in the direction of the chosen gradient. The direction is calculated for each iteration. Examples of these methods are Conjugate Gradients and Quickest Descent. The search method usually requires calculation of the objective function approximation in a neighborhood of the current point.

Optimization problems generally have three basic components:

- An *objective function* that needs to be minimized or maximized. For instance, in a manufacturing process, you might want to maximize the profit or minimize the cost. In fitting experimental data to a user-defined model, the total deviation of observed data can be minimized from predictions based on the model.
- A set of *unknowns* or *variables* that affect the value of the objective function. In the manufacturing problem, the variables might include the amount of resources used or the time spent on each activity. In fitting-the-data problem, the unknowns are the parameters that define the model.
- A set of *constraints* that allow unknowns to take on certain values but exclude others. In the manufacturing problem, it does not make sense to spend a negative amount of time on any activity, so all the "time" variables are constrained to be non-negative.

The overall goal is to *find values of the variables that minimize or maximize the objective function while meeting the constraints*.

Intel® MKL provides math optimization tools, namely the optimized Trust-Region (TR) solvers for nonlinear least squares problems with or without linear constraints.

Nonlinear Least Squares Problem

Nonlinear least squares problem can be described as follows:

$$\min_{x \in \mathbb{R}^n} F(x) = \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m > n,$$

where $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}$ is a twice differentiable function in $\mathbb{R}^n$. Solving of nonlinear least squares problem is searching for the best approximation to vector y with the model function that has nonlinear dependence on variables x . Best approximation means that the sum of squares of residuals is the lowest possible.

If

$$F(x) = \sum_{i=1}^m r_i(x)^2, \quad r_i(x) = y_i - f_i(x),$$

then

$$F(x) = \frac{1}{2} R(x)^T R(x),$$

where $R(x) = \{ r_i(x) \}, i = 1, \dots, m$.

Trust-Region Algorithm

The Trust-Region (TR) algorithms are relatively new iterative methods for solving nonlinear optimization problems. They are widely used in power engineering, finance, applied mathematics, physics, computer science, economics, sociology, biology, medicine, mechanical engineering, chemistry, and other areas. The TR methods have global convergence and local super convergence, which differentiates them from line search methods and Newton methods. The TR methods have better convergence when compared with widely-used Newton-like methods.

The main idea behind a TR algorithm is calculating a trial step and checking if the next values of x_+ belong to the *trust region* [Conn00]. Calculation of the trial step is strongly associated with the approximation model.

If the nonlinear least squares problem is defined as

$$\min_{x \in \mathbb{R}^n} F(x) = \|y - f(x)\|_2^2, \quad y \in \mathbb{R}^m, \quad x \in \mathbb{R}^n, \quad f: \mathbb{R}^n \rightarrow \mathbb{R}^m, \quad m > n,$$

then the trial step is a solution of the following subproblem:

$$\min_{d \in \mathbb{R}^n} \left\| F(x_k) + J(x_k)^T d \right\|_2^2, \text{ where } \|d\|_2^2 < \Delta_k \text{ and } J(x_k) \text{ is Jacobi matrix.}$$

This operation is an approximation to the objective function in a neighborhood of the current point x .

Consider a TR algorithm with **linear (bound) constraints** :

$$\min_{l \leq x \leq u} f(x) = \min_{l \leq x \leq u} \frac{1}{2} \|F(x)\|^2.$$

The first-order necessary condition for the vector to be minimized with this constraint is

$$D(x)^{-2} \nabla f(x) = D(x)^{-2} F'^T(x) F(x) = 0,$$

where D is the diagonal scaling matrix

$$D(x) = \text{diag}(|v_1^{-\frac{1}{2}}(x)|, |v_2^{-\frac{1}{2}}(x)|, \dots, |v_n^{-\frac{1}{2}}(x)|)$$

with

$$v_i(x) = \begin{cases} x_i - u_i & \text{if } \nabla f(x)_i < 0 \text{ and } u_i < \infty \\ x_i - l_i & \text{if } \nabla f(x)_i > 0 \text{ and } l_i < \infty \\ \min(x_i - u_i, u_i - x_i) & \text{if } \nabla f(x)_i = 0 \text{ and } u_i < \infty \text{ or } l_i > -\infty \\ -1 & \text{if } \nabla f(x)_i < 0 \text{ and } u_i = \infty \\ 1 & \text{if } \nabla f(x)_i < 0 \text{ and } u_i = \infty \\ 1 & \text{if } \nabla f(x)_i = 0 \text{ and } u_i = -l_i = \infty \end{cases}$$

for $i = 1, \dots, n$.

Provided $\Omega = \{x \in R^n: l \leq x \leq u\} \subset R^n$, write $\text{int}(\Omega)$ for the strictly nonempty interior of Ω . At each iteration, the basic structure of the method involves solving an elliptical trust-region subproblem and computing a search step to update the current iteration.

Provided $x_i \in \text{int}(\Omega)$ and the trust region size $\Delta_k > 0$, consider the elliptical trust-region subproblem

$$\min_p \left\{ F(x_k) + J(x_k)^T p : \|D_k p\| \leq \Delta_k \right\}.$$

Let $p_{tr}(\Delta_k)$ and $p_c(\Delta_k)$ be a solution and a Cauchy point of the above trust-region subproblem respectively [Conn00]. The following linear combination of two vectors $p_{tr}(\Delta_k)$ and $p_c(\Delta_k)$ defines the search step (trial step) used in the algorithm, that is,

$$p(\Delta_k) = t \bar{p}_c(\Delta_k) + (1-t) \bar{p}_{tr}(\Delta_k).$$

A good agreement between the model function m_k and the objective function f is ensured for the following standard condition:

$$\rho_f(p(\Delta_k)) = \frac{f(x_k) - f(x_k + p(\Delta_k))}{m_k(0) - m_k(p(\Delta_k))} \geq \beta_2$$

with the given constant $\beta_2 \in (0, 1)$. If this condition is not met, reject $p(\Delta_k)$, and the trust-region size Δ_k is successively reduced so that $p(\Delta_k)$ satisfies the accuracy requirement.

Glossary

A^H	Denotes the conjugate transpose of a general matrix A . See <i>also</i> conjugate matrix.
A^T	Denotes the transpose of a general matrix A . See <i>also</i> transpose.
band matrix	A general m -by- n matrix A such that $a_{ij} = 0$ for $ i - j > 1$, where $1 < 1 < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .
c	When found as the first letter of routine names, c indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. See BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable x . For univariate distribution the cumulative distribution function is the function of real argument x , which for every x takes a value equal to probability of the event $A: X \leq x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$, which, for every x , takes a value equal to probability of the event $A = (X_1 \leq x_1 \ \& \ X_2 \leq x_2, \ \& \ \dots, \ \& \ X_n \leq x_n)$.

Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^H U$ or $A = L L^H$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = \ A\ \ A^{-1}\ $.
conjugate matrix	The matrix A^H defined for a given general matrix A as follows: $(A^H)_{ij} = (a_{ji})^*$.
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \sum_i x_i y_i$. Here x_i and y_i stand for the i -th elements of x and y , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23 \times 10^{-308} < x < 1.79 \times 10^{308}$. For this data type, the machine precision ϵ is approximately 10^{-15} , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.

full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H . The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	See identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A , $AI = A$ and $IA = A$.
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A .
LQ factorization	Representation of an m -by- n matrix A as $A = LQ$ or $A = (L \ 0)Q$. Here Q is an n -by- n orthogonal (unitary) matrix. For $m \leq n$, L is an m -by- m lower triangular matrix with real diagonal elements; for $m > n$,

$$L = \begin{bmatrix} L_1 \\ L_2 \end{bmatrix}$$

where L_1 is an n -by- n lower triangular matrix, and L_2 is a rectangular matrix.

LU factorization	Representation of a general m -by- n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).
machine precision	The number ϵ determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See <i>also</i> double precision and single precision.

MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable x . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is

$$F(x) = \int_{-\infty}^x f(t) dt .$$

For multivariate distribution the relation is

$$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n .$$

positive-definitematrix	A square matrix A such that $Ax \cdot x > 0$ for any non-zero vector x . Here $\cdot$ denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
QR factorization	Representation of an m -by- n matrix A as $A = QR$, where Q is an m -by- m orthogonal (unitary) matrix, and R is n -by- n upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.

random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.
RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.
s	When found as the first letter of routine names, <i>s</i> indicates the usage of single-precision real data type.
ScaLAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A , triangular matrix) called the Schur form of A ; the matrix Z is orthogonal (for complex A , unitary). Columns of Z are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18 \times 10^{-38} < x < 3.40 \times 10^{38}$. For this data type, the machine precision (ϵ) is approximately 10^{-7} , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H . See also SVD.
SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. See BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. See full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. See also Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.

transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T , and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^H A = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. See Chapter 10 of this book.
z	When found as the first letter of routine names, z indicates the usage of double-precision complex data type.
